FOURTH EDITION

Trace Elements in Human and Animal Nutrition

By ERIC J. UNDERWOOD

After surveying the nature, occurrence, discovery, modes of action, requirements, tolerances, and metabolic interactions of trace elements, the author presents detailed discussions of individual elements, elaborating their chemical forms and distribution in the animal body, their absorption, metabolic movements and excretion, their biochemical and physiological functions, and their toxic effects in the cells. Descriptions of the clinical and pathological manifestations of deficiencies, imbalances, chronic toxicities, and sources as well as a critical assessment of minimum needs and maximum tolerances follow. Finally, the author introduces soil-plant-animal interrelationships, including environmental cycling of the elements and soil-water relations in human health and disease.

1977, 512 pp., $29.50/£20.95 ISBN: 0-12-709065-7

Chemical Evolution of the Precambrian

Edited by CYRIL PONNAMPERUMA

The second colloquium of the Laboratory of Chemical Evolution of the University of Maryland, held on October 29—November 1, 1975, at College Park, Maryland, explored the question of chemical evolution as it relates to the precambrian. The participants, consisting of geologists, chemists, and biologists, focused on the important questions, "When did life begin?" and "Is there any evidence for prebiotic processes on the earth?" The subsequent discussions entailed examining every aspect of the precambrian, from the formation of the earth's crust to the appearance of the first cell and its evolution to the eukaryotic organisms of the late precambrian. The papers in this volume represent the latest thinking and experimental evidence available on the early precambrian and will be of utmost interest to biologists, chemists, paleontologists, and geologists investigating the origin of life.

A new journal

PHYSICS AND CHEMISTRY OF MINERALS

Edited by S.S. Hafner, A.S. Marfunin, C.T. Prewitt

Advisory Board:
T.J. Ahrens, A. Authier, P.M. Bell, G.B. Bokiy, V. Gabis, T. Hahn, H. Jagodzinski, J.C. Jamieson, N. Kato, R.C. Liebermann, J.D.C. McConnell, A.C. McLaren, N. Morimoto, A. Navrotsky, R.E. Newnham, A.F. Reid, R.D. Shannon, D.W. Strangway, R.G.J. Strens, I. Sunagawa, V.M. Vinokurov, E.J.W. Whittaker, B.J. Wuensch

Physics & Chemistry of Minerals
is an international journal devoted to publishing articles and short communications of physical or chemical studies on minerals or solids related to minerals. The aim of the journal is to support competent interdisciplinary work in mineralogy and physics or chemistry. Particular emphasis is placed on applications of modern techniques or new theories and models to interpret atomic structures and physical or chemical properties of minerals. Some subjects of interest are:

- Relationships between atomic structure and crystalline state (structure of various states, crystal energies, crystal growth, thermodynamic studies, phase transformations, solid solution, exsolution phenomena, etc.)
- General solid state spectroscopy (ultraviolet, visible, infrared, Raman, ESCA, luminescence, X-ray, electron paramagnetic resonance, nuclear magnetic resonance, gamma ray resonance, etc.)
- Experimental and theoretical estimation of chemical bonds in minerals (application of crystal field, molecular orbital, band theories, etc.)
- Physical properties (mechanic, magnetic, electric, optical, etc.)
- Relations between thermal expansion, compressibility, elastic constants, and fundamental properties of atomic structure, particularly as applied to geophysical problems.
- Electron microscopy in support of physical and chemical studies.

INTRODUCTION TO GEOLOGY: Volume 2 EARTH HISTORY

H.H. Read & Janet Watson

Part 1 EARLY STAGES OF EARTH HISTORY
Part 2 LATER STAGES OF EARTH HISTORY

This scholarly work by two acknowledged experts consists of two parts which together provide a comprehensive outline of earth history covering the whole of the geological time span as well as every continent. Part 1 carries the record to late Precambrian times, Part 2 covers the last thousand million years.

The authors have integrated the records of events that took place at or near the earth's surface with those of tectonic, metamorphic and magmatic events occuring at depth in the crust. The development of large geological units such as mobile belts and basins of deposition are emphasised. Local details are presented where appropriate in relation to the evolution of these units. Economic deposits are discussed in the same context.

The treatment of earth history is based on the concept of a long-term rhythm in the mobility of the earth's crust. The principal divisions of the two Parts deal with successive repetitions of this crustal rhythm, while individual chapters are arranged on a regional basis.

This is the second volume of *Introduction to Geology*. Volume 1, *Principles*, was first published in 1962, with a revised second edition in 1968.

Volume 2
Part 1 hardcover £5.95, paperback £2.95
Part 2 hardcover £6.95, paperback £3.95

For further details and inspection copies, please write Rosemary Hamilton (N), The Macmillan Press, Little Essex Street, London WC2R 3LF

Sedum of North America

Sedum *of North America, North of the Mexican Plateau.* By Robert T. Clausen. Pp.742. (Cornell University: Ithaca and London, 1976.) £42.25.

Sedum is the largest genus of the family Crassulaceae and consists of about 300 species, most of them in the north temperate zone but some on subtropical and tropical mountains. They are succulent plants, usually low-growing and small-leaved, and on account of their general easiness of cultivation and propagation and their numerous small starry flowers they have long been esteemed as rock-garden plants. Their garden value led an Irish botanist, Robert Lloyd Praeger, to publish in 1921 an account of the genus *Sedum* as found in cultivation (*J. R. Hort. Soc.*, **46**, 1-314), describing and illustrating 151 species, still a most useful work. A Swedish botanist, Harald Fröderström, published between 1930 and 1935 a survey of the genus as a whole in *Acta Horti Gothoburgensis*, distinguishing 327 species. Neither competes in bulk and wealth of detail with Robert T. Clausen's *Sedum of North America*, which devotes 742 pages to some 90 species, only 36 of them native. Unlike other workers on the genus, which he has studied intensively since 1935, Professor Clausen has been able to examine wild populations of almost every North American species and has supplemented his field surveys by experimental culture at Cornell University. Thus he has been able to separate environmental modifications from genetically fixed characters.

The result is this comprehensive monograph admirably illustrated with various sketch maps and with line drawings of all the species by Elfriede Abbe, who earlier provided those in Clausen's *Sedum of the Trans-Mexican Volcanic Belt* (1959). That work set out to be "an exposition of taxonomic methods", not simply a concise working account of 28 Mexican species, and provided a prolixity of detail irrelevant for almost all its users. In *Sedum of North America*, because the area covered is about 216 times larger (though with almost the same number of species), the same treatment has resulted in this huge and expensive work. It raises the question as to whether the printing (as distinct from the research and recording) of so many measurements in the diffuse paper-covering style of this book is justifiable nowadays, since the information relevant for most purposes could have been presented in a volume of less than half the size and half the price. It thus suffers from a defect produced by its major virtue. Having worked so long, so thoroughly and so successfully at understanding these plants which can indeed only be properly evaluated from living material studied both in the wild and under cultivation, Professor Clausen has evidently felt he must publish everything, an honest enough procedure but costly. Thus his account of *Sedum spathulifolium* occupies 35 pages; he nevertheless leaves somewhat uncertain Praeger's var. *purpureum*, of which he has seen no material, although this is still cultivated in England.

For anyone interested in the *Sedum* species of North America, their characters, population variation, nomenclature, distribution and identification, this work will be indispensable, which makes its high cost all the more regrettable. Likewise regrettable is the lack of attention to page headings; instead of the verso heading throughout the book unnecessarily proclaiming that it deals with "Sedum of North America", it could more usefully have given the chapter heading, while the recto heading then named the species dealt with beneath, which is often not evident. One hopes that some day Professor Clausen will produce a convenient illustrated handbook to the genus *Sedum* in America as a whole, summarising concisely the results of his many years of painstaking enquiry. **W. T. Stearn**

W. T. Stearn is Honorary Botanical Curator of the Linnean Society, and was formerly a Senior Principal Scientific Officer at the British Museum (National History).

Statistical mechanics of liquids

Theory of Simple Liquids. By J. Hansen and I. R. McDonald. Pp. xv+395. (Academic: London and New York, 1976.) £14; $30.65.

RECENT years have shown an upsurge of interest in the statistical mechanics of liquids, which has been marked by a number of important advances. The advance has been continuous since 1957; the previous history of the subject had been a series of fundamental advances, with long gaps in between.

This book is a timely and balanced survey of recent developments, shows how they are related to the older work, and explains the relationships between the various theoretical approaches. The year 1957 showed that the task of evaluating the correct consequences of an assumed intermolecular interaction function was within the power of large computers and this has stimulated a great deal of further work. One good feature is a special chapter describing techniques of these computer calculations.

The days of analytical results in this field are, however, very far from over, and these approaches are described in chapters 4, 5 and 6. Basically what has happened is that the fundamental advances made by Kirkwood (the feasibility of an integral equation approach) and by Mayers (the diagram expansion technique) have been systematically followed up and improved. It has also been found possible to develop perturbation theories analogous to those of quantum mechanics and celestial mechanics. These three chapters provide a connected account of these developments, contain very little repetition and are a pleasure to read.

Some workers consider equilibrium statistical mechanics to be difficult enough and fight shy of transport processes. A large amount of work has, however, been carried out, and is well summarised in chapters 7, 8 and 9, which the reviewer, largely an 'equilibrium man', found most helpful. In reading a published paper in this field it can be quite difficult to separate the formalism and the 'intelligent guesswork' or to see whether any difficulties of principle are being glossed over. These chapters will certainly be helpful to many workers, as will the account of generalised hydrodynamics, hard to find elsewhere except in original papers.

I was disappointed to see no mention of surface tension and related phenomena. One of the first definite results in liquid-state theory was Laplace's relation between surface tension and latent heat, and the subject was again opened up by the pioneer work of Kirkwood and Buff. Many of the published papers are, however, obscure and complicated; perhaps lack of space was the deciding factor. The final chapter, on phase transitions, seems to have suffered for a similar reason. The discussion of melting is as good as could have been hoped for in the present rather fragmentary state of knowledge but I would have liked to see a far more extensive account of the critical region. In particular, I would have liked to know the authors' own views on the following point. Why do scaling and renormalisation group methods provide good results despite the fact that they seem to use approximations just as drastic as those that vitiated older theories of phase transitions?

The book is well printed and produced but the price seems on the high side even at present levels. There is a valuable bibliography and a good index.

Drama of environmental physiology

Environmental Physiology of Animals. Edited by J. Bligh, J. L. Cloudsley-Thompson and A. G. MacDonald. Pp. viii+456. (Blackwell Scientific: Oxford, 1976.) Cloth £18; paper £9.50.

THIS book is a multi-author text for degree-level students who have at least some knowledge of physiology and ecology. Its scope is very wide for, as the editors state in a postscript (p434) "Between a mutation and the resultant marginal benefit detectable in a population there lies an enormously complicated drama acted out by individual organisms in an environment which is certainly indifferent and often hostile. Environmental physiology *is* this drama, and is thus the central subject of biology. It embraces the intracellular molecular biology which accounts for the occurrence of mutations, as well as classical unicellular and multicellular morphology, physiology, biochemistry and ecology. It demands the ability to think at different levels of analysis—at those of molecules, of cells, of organisms and of populations, because organisms adapt in different ways at these different levels".

The text is divided into four main sections, and there is also an editorial introduction (part I) and postscript (part VI). Apart from the editorial contributions, the main text consists of a short section (part II) of two chapters on the origin of life and the evolution of the oceans and atmosphere. This is followed by a major section (part III) of seven chapters on adaptive mechanisms which have resulted from long-term evolutionary changes. It includes excellent reviews on ionic and osmotic regulation in aquatic animals, water balance and excretion, gas exchange, and reproduction. Part IV on acquired adaptations contains a well-coordinated and stimulating series of chapters on non-genetic adjustment to change in environmental conditions. This is followed by a section (part V) on immediate homeostatic or sensory responses. The latter contains chapters on sensory physiology, buoyancy, colour change, and temperature regulation.

A feature of this book is the contributions by the editors to coordinate the text so that contributory chapters can be placed clearly into the context of the framework of the book as a whole. It is a praiseworthy attempt to overcome some of the problems associated with multi-author texts, and some of the prefaces and introductory chapters to each section are quite outstanding. Chapter 11 introducing the concept of acclimatory adaptation and chapter 16 on rapid responses of organisms to environmental change, are especially clear in introducing later chapters in each section. Other chapters are, however, less successful in this respect and are in places even slightly ludicrous in attempting to unite environmental concepts with those of physiology. After identification of the principal terrestrial environments in chapter 6, for example, the reader is informed (p102) that "The topography of the land and variations of its climate represent the same part in the make up of the environment, figuratively speaking, as morphology and physiology do in the life of an animal (12). Thus irrespective of climate, the mammalian fauna of desert, savanna, steppe, tundra and high plateaux have certain features in common". I was unable to fully understand either the precise meaning of the analogy attributed to Haviland (1926), or the logic of its relationship with the statement that follows it.

It was a little disappointing to find that there was no chapter on sense organs in the section on evolutionary aspects, and that no detailed consideration was given to topics such as accoustic interactions between bats and their prey in chapter 17, a topic which would surely have fitted in well with the concepts underlying the theme of this book. It was also slightly surprising to find in the chapter on locomotion that there were no diagrams of how fishes, quadrapeds and flying animals actually conform to Newton's three Laws of Motion, despite the excellent prelude to chapter 8 stating these as underlying principles. Perhaps these were assumed to be well-known from other texts, but it would surely have been well-worth illustrating them in a comprehensive book designed for the undergraduate level.

The contributions overall are of very high quality, and are remarkably free of mistakes. The book has been well compiled and conscienciously edited so that, in general, individual chapters are well-balanced reviews which fit the stated theme of the book. The continuity is greatly aided by the editorial contributions, some of which are exceptionally stimulating. This book will be a welcome addition to the shelves of the physiologist and ecologist. It is enjoyable to read and is to be highly recommended for courses in environmental physiology at university level. **R. C. Newell**

R. C. Newell is Professor of Environmental Biology at the Institute of Biology, Odense University, Odense, Denmark.

Nematodes

The Organization of Nematodes. Edited by N. A. Croll. Pp. viii+439. (Academic: London and New York, 1976.) £15; $32.75.

THIS multi-author volume contains fourteen chapters which describe various aspects of the structure, physiology and biochemistry of nematodes. The controversial topic of nematode taxonomy is discussed in the first chapter and is followed by chapters which review, to a greater or lesser extent, energy metabolism; the functional organisation of the head; the development and organisation of skeletal structures; sense organs and their secretions; nitrogen excretion, osmotic and ionic regulation; nematodes as models for ageing studies; respiratory physiology; hormones; neuromuscular physiology; the mechanics of feeding; behavioural coordination; the use of mutants to analyse the sensory system; and survival strategies.

The individual chapters of this book are of a high standard, and some are excellent. In a book with this title, however, one would expect complete coverage of all fields of the organisation of nematodes, but the alimentary system, with the notable exception of the oesophagus, and the reproductive systems, with the exception of the spicules and the eggshell, are not included; yet these are major systems in nematodes.

The reviews are also not grouped in a logical manner. This may be deliberate policy to emphasise the individual nature of each chapter, but one would, for example, expect to find energy metabolism, respiratory physiology and nitrogenous excretion dealt with in adjacent chapters. There is also overlap of subject matter in several chapters. This is inevitable in a multi-author volume, but sense organs, for example, are described in chapters 3, 5 and 13, with no cross references. It is unfortunate that the authors of these particular chapters were apparently not given access to each other's manuscripts. Several chapters are comprehensive reviews of the subject, whereas some others deal with a smaller number of examples or topics in greater depth. Some chapters include important work which has not previously been published. It is a matter for regret that the plates, especially the electron micrographs, do not occupy more of the page, as certain details have been lost as a result.

This book is a significant contribution to the literature on nematodes, and will be extremely useful to those who teach and carry out research on these important animals. It will also be heavily used by students who wish to pursue, in depth, the various topics dealt with in the book. **D. L. Lee**

D. L. Lee is Professor of Agricultural Zoology in the Department of Pure and Applied Zoology at the University of Leeds, UK.

HYPERTENSION

Two Key Books

Hypertension and Brain Mechanisms

edited by W. DE JONG, A. P. PROVOOST *and* A. P. SHAPIRO

PROGRESS IN BRAIN RESEARCH, Vol. 47

1977. about 380 pages.
US $ 57.95/Dfl. 142.00. ISBN 0-444-41534-3

This book contains contributions by over forty international authorities on the control of arterial blood pressure by the brain. These centre on three main areas: 1) integration of neuroanatomy, neurophysiology and neurotransmission of the central nervous system in relation to cardiovascular control and emotional behavior in man and animal; 2) brain damage, i.e. infarction, blood flow disturbances, stroke, etc, resulting from hypertension and vice versa; 3) evaluation of brain mechanisms in drug and non-pharmacological treatment of hypertension, including bio feedback, relaxation techniques and the role of the social environment.

The wide scope of this book makes it of interest to researchers concerned with hypertension as well as to those engaged in its treatment. It will be of great value to clinicians, physiologists and pharmacologists and also to neurologists and psychologists.

CONTENTS: Neuroanatomy and neurophysiological mechanisms of central cardiovascular control. Neurotransmission in relation to cardiovascular control. Brain damage and hypertension: experimental and clinical. Integrated brain function and hypertension. Pharmacological aspects of central acting antihypertensive drugs and influence on peripheral effector mechanisms. Subject Index.

Control Mechanisms in Essential Hypertension

by W. H. BIRKENHÄGER *and* M. A. D. H. SCHALEKAMP

1976. xviii + 182 pages.
US $26.75/Dfl. 65.00. ISBN 0-444-41452-5

from the introduction

"Professor Birkenhäger and Dr. Schalekamp have themselves made great contributions to knowledge by their wide researches into haemodynamic, renal, functional and humoral influences in essential hypertension. They are particularly fitted therefore to collate the rapidly expanding corpus of world knowledge in this field and this they have done with commendable fairness and critical appraisal."

CONTENTS: Blood pressure as a variable. Systemic haemodynamics. Renal haemodynamics and renal function. Body fluids in essential hypertension. The adrenergic system in essential hypertension. Renin, angiotensin and aldosterone. Autoregulation: a factor in the genesis of hypertension? Cardiovascular reactivity and volume control during antihypertensive drug treatment. The pathophysiological profile of essential hypertension as a guide to treatment. Speculations. Subject index.

"Professor Birkenhäger and Dr. Schalekamp have made a substantial contribution to our knowledge of the regulation of the circulation in hypertension, and their book is a balanced review of this difficult and contentious subject."

WILEY
INTERSCIENCE

ABNORMAL AGEING: The Psychology of Senile and Presenile Dementia

by **E. Miller**, *University of Southampton.*

Ageing is rightly a topic of increasing concern and research interest. The growing proportion of the elderly in the population raises many important issues for society, and presents some problems. Dementia is one of the commonest and yet most difficult disorders found in older people, and the basic aim of this book is to present the psychological aspects of dementia.
The author reviews what is known about the psychological changes produced by dementia and discusses the practical contributions that psychology can make in dealing with the demented individual.

0471 99439 1 176 pages February 1977 £5.75/$11.00

PHARMACOLOGY: Drugs Affecting Behavior

by **C. Kornetsky**, *Boston University School of Medicine.*

Describes the physiological and psychological effects of drugs used in treating the mentally ill, the epileptic, and the hyperkinetic child, and presents various theories concerning the mechanisms involved in the therapeutic action of drugs and the pharmacology of abused drugs.

0471 50410 6 288 pages September 1976 £14.00/$24.50

IMMUNOCHEMISTRY OF ENZYMES AND THEIR ANTIBODIES

edited by **M. R. J. Salton,** *New York University Medical Center.*

Leading medical scientists pool their collective experience to formulate basic principles for the interaction of enzymes and antibodies and explain how these interactions can be used to solve complex molecular and biological problems. Features selected model systems illustrating the use of enzyme/antibody interactions to establish molecular structure and architecture of enzymes. (Developments in Medical Microbiology and Infectious Diseases).

0471 74995 8 240 pages February 1977 £14.25/$24.15

IMMUNOBIOLOGY FOR THE CLINICIAN

by **H. R. K. Barber.**

A concise, overall view of the basic concepts and recent developments in immunology. Topics include: Structure of a Normal Cell and Cancer Cell Kinetics; Immunity, Antigens, and Viruses in Relation to Cancer; Immunodeficiency Diseases; Immunohaematology; Immunosuppression; Immunology of Cancer; Immunotherapy and Immunopotentiation.

04710 4785 6 320 pages February 1977 £14.65/$24.75

TROPICAL CLIMATOLOGY: An Introduction to the Climates of the Low Latitudes

by **S. Nieuwolt,** *Department of Geography, Kenyatta University College, Nairobi.*

This textbook is intended for students of geography, biology and agriculture whose studies include a course on the climate of tropical regions and the effects of the weather upon man's activities in these regions.
The book explains the origin of the tropical climates in a non-mathematical way and all quantitative data are illustrated by maps and diagrams.

0471 99406 5 218 pages February 1977 £6.95/$15.00

GEOLOGY OF CALIFORNIA

by **R. M. Norris** and **R. W. Webb,** *both of University of California, Santa Barbara.*

The first systematic, comprehensive text covering major fundamental elements of the geology of California. The book incorporates the most recent research on the basic geology of the earth's crust as reflected in the visible geology of the provinces of the state of California.

0471 61566 8 392 pages February 1977 £9.35/$16.00

CELLULOSE AS A CHEMICAL AND ENERGY RESOURCE

edited by **C. R. Wilke,** *University of California.*

This contains papers by scientists and engineers actively involved in research related to cellulose. The papers were presented at the Cellulose Conference Proceedings, held under the auspices of the National Science Foundation, at the University of California, Berkeley, June 1974.

0471 01549 0 370 pages March 1976 £14.50/$25.20

MICROPROCESSORS AND MICROCOMPUTERS

by **B. Soucek,** *State University of New York, Stony Brook and Institute Ruder Boskovic, Zagreb.*

Describes the general programming and interfacing techniques common to all microprocessors, concentrating on detailed description of representative microprocessor families. Numerous illustrations, examples and a bibliography are provided along with exercise problems.

0471 81391 5 624 pages April 1976 £17.00/$29.75

newly on the market

These descriptions are prepared by the staff of *Nature* on the basis of material provided by manufacturers. There is a Reader Enquiry Form on page xxi.

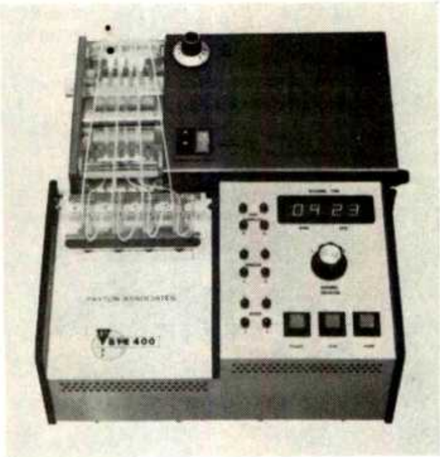
HPLC Column Injector System. Shandon Southern. The system comprises an optimised septum injector or an adaptor allowing the use of other injectors, a range of columns up to 8 mm bore, and a packing tube for slurry packing. These are designed as a unified system and combine the high efficiency of syringe injection with a standard of reproducibility normally associated with valve injection systems. Both analytical and small scale preparative chromatography are possible.
Circle No. 33 on Reader Enquiry Form

High-Resolution Underwater Detection System. Marconi. A digital sonar navigation, positioning and detection aid for the location, tracking and recovery of underwater objects such as wellheads, pipelines and divers known as Marfix, this portable acoustic detection system employs a new method of sonar electronic scan. Marfix comprises three main units: a processor, a display and a portable transducer which can be mounted on most vessels to scan either horizontally or vertically.
Circle No. 34 on Reader Enquiry Form

Digital readout refractometer. Anacon. The Model 42 provides instantaneously a digital LED display of refractive index and sample temperature. The readout can be calibrated in refractive index, percentage, degrees Brix or any other relevant unit and produces a repeatability of ±0.0002 RI. Provision of external water bath connections allow sample temperature control. Size: 13×6×10 in; weight 15 lb.
Circle No. 35 on Reader Enquiry Form

Automatic audiometer. B & K Laboratories. The Type 1800 Audiometer will provide extremely accurate and reliable automatic recordings in less than 10 min per individual, is for Bekesy type audiometry and provides a series of pure tone signals at seven different frequencies from 500 to 8000 Hz, either pulsed or continuous.
Circle No. 36 on Reader Enquiry Form

In vitro **Bleeding Time Recorder.** Payton Associates. The BTR–400 replaces the traditional *in vivo* method eliminating some of the limitations and undesirable aspects e.g. trauma, repeated incision, and scarring. It also minimises the risk of infection. Simultaneous determinations of up to four different blood samples are possible. Blood is pumped at a constant rate through tubes, near the end of each of which is a minute orifice. Drops of blood fall through a photo-sensitive detector and this information is translated into bleeding time, stored in a memory module, and displayed via a 4-way selector switch on a digital (LED) counter. The Payton system also facilitates mixing experiments and provides ready access to the hemostatic plug for further study.
Circle No. 37 on Reader Enquiry Form



Payton BTR-400

Minature cryogenerator. Pye Unicam. The type MC80 Mini-Cooler is an extremely compact, lightweight cryogenerator able to produce temperatures down to 80 K within 15 min.

The MC80 measures 38 cm high and weighs 6 kg. Operating on the Philips–Stirling principle,. the MC 80 produces a cold output, approximately liquid nitrogen temperature, at a copper 'cold finger' normally situated inside a transparent bell-jar vacuum head; there is provision for pneumatic lines and electrical connections to be made through the vacuum wall allowing observation of experiments carried out in the bell-jar.
Circle No. 38 on Reader Enquiry Form

Resonant optical scanners. Techmation. Operating on the oscillating torsion bar (bearingless) principle, these motors exhibit an extremely long mechanical life and are designed for use in applications where a single frequency between 100 Hz and 2 kHz, fixed scanning angle and extreme reliability are required. They show a high order of amplitude stability (0.6% per °C) and are supplied complete with precision mirror.
Circle No. 39 on Reader Enquiry Form

High versatility SEM/X-ray system. Philips. A high-performance scanning electron microscope PSEM 500 interfaced with a fully-focusing wavelength dispersive X-ray spectrometer, the PSEM 500X, not only permits analysis of X-rays from $Z=5$ to $Z=92$ but is the first such system to use the vertical spectrometer orientation—a configuration which offers the highest mechanical reproducibility—without the need for an optical microscope. Instead, a new standard in specimen height accuracy and reproducibility is achieved via the unique, fully-eucentric goniometer coupled with its 4,6 mm fine Z-adjustment (in 0,2 μm steps) and the large (210 mm) Rowland circle of the spectrometer. An extremely high-vacuum system (10^{-6} torr, inclusive of the spectrometer assembly) vastly improves practical light-element detection. Thus, absorption of 'soft' X-rays from light elements, due to specimen contamination, is seldom encountered. The same vacuum system, without modification, allows operation with optional higher-brightness sources—a particularly valuable facility for excitation of X-rays from light elements. The standard 50 kV electron optics of the PSEM 500 is ideal, when using an energy dispersive X-ray detection system, for unambiguous excitation of K-line X-rays from heavier elements. The larger excited volume of X-rays, when using 50 kV electrons, can also facilitate easier trace-element detection. The energy dispersive and wavelength dispersive spectrometers can be in operation at the same time, thus giving an optimum choice of the characteristics of each type of spectrometer.
Circle No. 40 on Reader Enquiry Form

CO_2 Incubator. Assab. In the T304GF, temperature is controlled within the range +25 °C to +75 °C to a tolerance of ±0.3 °C throughout the cabinet. The CO_2 level, ranging from 0 to 25%, is continuously analysed and controlled through the use of a thermal conductivity sensor which responds rapidly to changes in CO_2 as small as 0.1%. This system ensures the most economical use of CO_2 and rapid recovery of the preset level following door opening. Humidity is produced by the controlled recirculation of the cabinet CO_2/air mixture through a water bath. A polymer foil hygrostat, accurate to ±2.0% RH, senses the relative humidity and operates the circulating pump accordingly. Both temperature and Co_2 control centres are solid state plug-in units which can be easily replaced. Controls are provided to set required levels which are displayed on digital meters. If required, visual or audible high/low alarms can be specified for temperature and CO_2 functions. Dimensions: 800×600×600 mm.

Circle No. 41 on Reader Enquiry Form

Scanning electron microscope. Philips. The SEM 501 has a guaranteed 70 Å resolution which can be consistently achieved and often exceeded and uses a three lens optics achieving a wide range of illuminating conditions. Its illumination efficiency, smallest spot size of 40 Å and low magnetic field at the specimen all combine to give high resolution images. Specimen positioning, at any magnification within the standard ×4 to ×160,000, is easily attained. The SEM 501 incorporates TV rate imaging, 30 kV electron optics, micron marker, independent number of lines and line time selection, high resolution photomonitor, digital display of magnification, *Y* modulation, a modular specimen rotation unit.

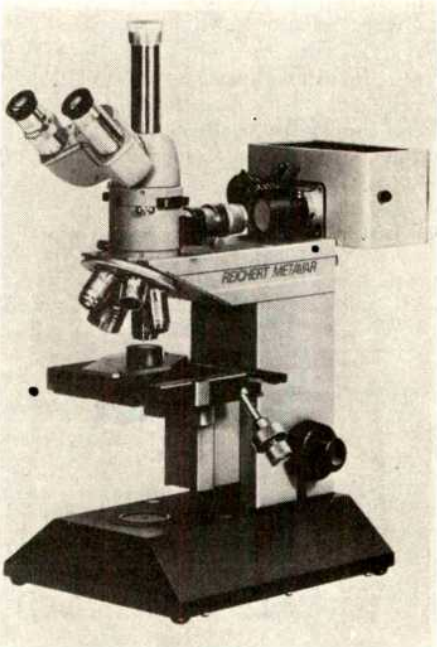
Circle No. 42 on Reader Enquiry Form

Electronic motionless switch. Siemens. A reliable, long-lived piezo-electric motionless switch for the direct control of ICs. The fully encapsulated switches can be used separately or grouped to construct switch panels and can be operated off symmetrical or asymmetrical voltages between 4 and 30 V, generates a current of 60 mA (adequate for miniature relays) for roughly 0.3 s under a brief pressure of around 150 g. In contrast to inductive proximity switches, this switch must be actuated by a defined pressure. A red, green or yellow light-emitting diode under a cap, which can be removed for the insertion of inscriptions, indicates the switch status

Circle No. 43 on Reader Enquiry Form

Metallurgical microscope. Reichert-Jung. The MetavaR microscope has a series of variants which enable all known metallurgical examination techniques to be undertaken and uses an identical stand throughout the range but alternative optics and illuminators depending on the technique. The incident light equipment is available in three options either for bright field polarisation, dark field or interference contrast. They are easily and accurately fitted or interchanged between stand or viewing tube. The S is for polarised light and bright field examination, the U is for examinations in bright field, dark field and polarised light; and the IK is for interference contrast, polarised light and bright ground examinations. Supplementary equipment for the series includes dual viewing projection screen, camera systems and drawing apparatus.

Circle No. 44 on Reader Enquiry Form



Reichert-Jung MetavaR metallurgical microscope

Uric Acid Clinical Diagnostic Kit. Pierce Chemical. The kit uses a unique method for quantative serum uric acid determination. Its direct serum procedure eliminates deproteinisation, and its unique two-tube method eliminates interferences from common drugs and native serum constituents. Absorbance values are linear to 20 mg dl^{-1}. The test can be run in a little over 35 min and colour development takes place within 15 min at room temperature. The final colour is stable for 90 min. The uricase is stable refrigerated; all other sonstituents are stable at room temperature.

Circle No. 45 on Reader Enquiry Form

Automatic sampling system. Hewlett–Packard. Batches of up to 60 samples can now be analysed automatically in sequence, and in replication if desired, by HP1084A and HP1082A processor-controlled liquid chromatographs. Only the sample amount injected is consumed by the system, making it possible to use micro-vials where only small samples are available.

A detachable unit containing 60 glass vials is located on top of the liquid chromatograph. A variable-volume sample injector, a standardd part of the chromatograph, then samples each vial in numerical sequence. The injection volume can be pre-set manually at any point between 10 and 200 μl.

Circle No. 46 on Reader Enquiry Form

Helium liquefier refrigerator. Sulzer. The Turbocryofridge TCF100, has a choice of two oil-free compressors, enabling a large number of plant variants to be achieved. By using the larger compressor and the cold box to its full extent with liquid nitrogen pre-cooling, it is possible to increase the minimum capacity of 10 l He/h (40 W at 4.5 K) to 80 l He/h (180 W at 4.5 K). For the generation of the necessary refrigerating capacity, the cold box is equipped with one or two turbo-expanders, each with dynamic gas bearings which operate at room temperatures. Braking is by a direct-coupled, single-stage centrifugal compressor.

Circle No. 47 on Reader Enquiry Form

TV attachment for light microscopes. Teletronics. A new closed-circuit TV attachment for multi-purpose microscopes, enables many people to view the same microscope slide simultaneously. The new system comprises a mini-CCTV camera, a 9-inch black-and-white TV monitor, and an attachment to link the camera to the microscope. Suitable for use with routine/research/biological microscopes having a sleeve of 23.2 mm inside diameter, the system gives users several options: camera-to-monitor cable distance can be from 1.5 to 100 m; the high-resolution 9-inch monitor can receive input from up to three cameras; and the monitor can be augmented by up to 10 additional monitor screens.

Circle No. 48 on Reader Enquiry Form

Automatic Colony Counter. Oriel Scientific. The Lab-Counter is an automated system giving fast and accurate counts of various types of samples both translucent and opaque. More than 700 samples per hour can be counted. The following samples can be taken by using the appropriate sample holder: microscopic slides, petri dishes 50–100 mm, tissue culture flasks, photographic films, filter dishes or photographs.

Circle No. 49 on Reader Enquiry Form

Why believe all our claims for the new SEM 501?

The new SEM 501 gives you better micrographs, consistently, more conveniently than with any other competitive scanning electron microscope.

That's our claim.

Don't believe it until you prove it for yourself. Bring your own samples. Sit in the driver's seat of our SEM 501.

Feel for yourself how convenient it is to operate.

Experience for yourself the benefits of a built-in eucentric goniometer.

See for yourself the uncompromised quality you get from the videoscope and unique greyscale generator. . . and better than 70 Å resolution time after time.

Learn for yourself what SEM versatility really means!

While you're here, learn about our unmatched total support service.

What you see in our lab you'll get in your lab.

That you can believe!

Philips Industries, Electron Optics Department,
Building TQ III-2 Eindhoven, The Netherlands.

Just sit in this driver's seat!

Seeing is believing!

☐ I'd like to sit in the driver's seat of your new SEM 501 Please contact me for a personal demonstration.

☐ For the time being, full documentation will do.

☐ Put me on your mailing list for technical/application bulletins.

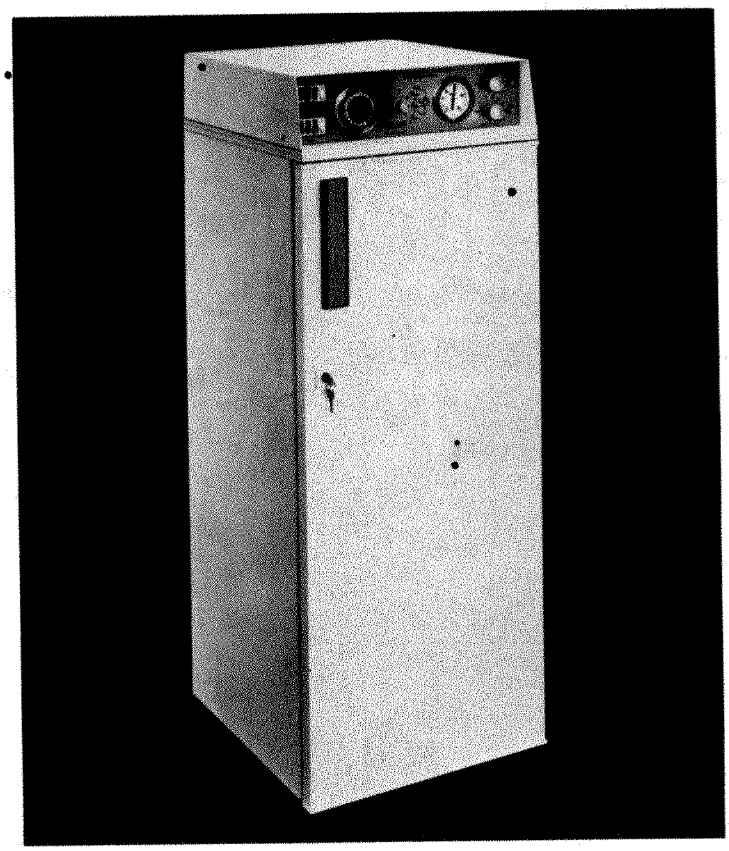
Gallenkamp

Cooled Incubators -dependability



Incubators must be dependable otherwise they're useless. The Gallenkamp range of cooled incubators is designed to keep your work at the temperature you choose. A Compenstat solid state thermostat provides accurate temperature control, and for additional security, high and low temperature adjustable safety thermostats are built into all models.

Our cooled incubators cover a range of 0 to 45°C, in ambient temperatures up to 30°C. Features such as temperature cycling, internal illumination and inner perspex doors are available, and one model is designed to allow incubation in CO_2 enriched atmospheres. Your work is valuable! A dependable Gallenkamp incubator will take great care of it.

The quiet side of technology

How many people understand what the state does on our behalf in prisons, in conflicts such as that in Northern Ireland, or in the murky world of demonstrations, pickets and strikes? And how well aware are scientists and technologists of the uses to which the armed forces, the police and the prison service put science and technology in pursuit of domestic policies? There is general and widespread ignorance of these subjects, and so the appearance of *The Technology of Political Control,* by Carol Ackroyd, Karen Margolis, Jonathan Rosenhead and Tim Shallice (Penguin £1.25), should have been welcomed as a guide to an uncharted area. But the book, which stems from investigations organised by the British Society for Social Responsibility in Science (BSSRS), is too ill-focused, full of ideology and lacking in constructive thinking to have anything like a major impact on the scientist who knows little and wants to know more.

The authors themselves write that their approach 'may seem a curious amalgam of technological exposé and political analysis' and indeed it is. The first half of the book is devoted to a rambling analysis of the steps by which Britain could move towards being a 'Strong State', obsessed less with the threat from without than with that from within as it lays plans in anticipation of social conflict. Such a strong state would have learned a lot from the Northern Ireland experience and would practise the sort of low-intensity operations described by Frank Kitson in a book of that name. The army, more closely integrated with the police, would play a significant role in putting down insurgency.

If you believe, as do the authors, that the major function of the British legal system is to protect property, that the events of the twentieth century are increasingly posing the question of socialism or barbarism and that any new working class revolution will have to ensure that ultimate power resides with the working class, then you will probably accept their analysis. A less class-conscious view of the world would probably not reveal quite the same trends, but that is not the point. The point is, as the authors insist, that they are writing as 'concerned scientists and committed socialists'. The actual technology of political control is therefore at least as important.

The technology occupies the second half of the book and amongst other things includes phone-tapping, bugging, computers, sensing equipment, riot control techniques, method of psychological torture and misuse of psychiatry. It is described as a 'vast and grim catalogue available to Western governments'. But the detail contains few surprises. Indeed, it is one of the disappointments of the book that it draws so widely on newspaper cuttings and so little on detailed research by the authors. Given the grass roots contacts BSSRS has been developing in the past few years, such research surely ought not to have been impossible.

Take the example of the computer. The police and the army already use computers as data banks, of course, and these uses are described. It takes little imagination to spot that computers may have a broader role to play in stitching together low grade information: as one Pentagon enthusiast put it some years ago, given an adequate computer network in Northern Ireland, one could put all sorts of information together, such as that Mrs O'Reilly hasn't gone out for her daily walk to the baker's, and come up with suggestive patterns of use to the security forces. But if this is true and it has been done, it poses all sorts of questions about the privacy of the individual. The authors only very tangentially pick up this issue, either technically or in its implications, and give little sign of persistent enquiry. So it seems with many other technical issues.

To the authors of this book, modern technology in the service of the state's law enforcement agencies is clearly an affront because it is or will be used to keep down working-class-generated insurgency and revolution. But what do they say scientists should do? It is here that the book is at its weakest and briefest. The answer seems to be that they should work politically for the abolition of the capitalist state and the establishment of a workers' militia in place of the capitalist army.

Those who take a less extreme view will be more likely to say that many of the problems of technology and political control are not amenable to such neat solutions. In Northern Ireland there is now plenty of technology on both sides, none of it particularly palatable, and talk of working-class control is meaningless. In other less strife-ridden parts of the country the unspectacular recipe is eternal vigilance. Technology does indeed have its role to play in law enforcement, and law enforcement agencies would be remiss if they did not use technology to the full. But the question is at what place use becomes abuse, reasonable enquiry becomes harassment, monitoring becomes intrusion. This can only be solved on a case-by-case basis, with at least some sort of trust in political institutions. The real need is for scientists who are involved in military and police research to be able to speak up when they see the balance shifting in an unsavoury direction. ☐

Directing Cuba's science

Mahindra Naraine, recently in the Caribbean, assesses the achievements of Cuba's science policy

IN FEBRUARY of last year, Cuba proclaimed a new constitution and established a new governmental system which transformed its existing central administration: ten months later, in December, the Council of Ministers—effectively the new Cuban government—was appointed by the National Assembly. The country was no longer ruled by decree, and elections had been held. The changes, marking the fourth phase of Cuba's modern history (see box), are now having their impact on the country's science and technology policy.

The institutional and infrastructural framework that the new order supercedes had a chequered record. It was characterised by the conscious promotion of science and technology—training personnel, creating research institutions, establishing means of international collaboration and starting research projects. Thus, in 1962 a new Academy of Sciences was created. In conjuction with the Soviet Academy of Sciences it assessed the country's natural resources, and, had as its first priority the creation of a soils map and national atlas. Other institutes were also established: the Institute for Sugar Cane Research, the Meteorological Institute, the Institute for Scientific and Technical Documentation and the Institute of Nuclear Research. In addition, the Ministry of Industry decided to set up special institutes to seek immediate or long term policies for the use of natural resources; these included institutions for the study of sugar cane by-products, mineral research, chemical research, meteorological research, standards and metrology.

In 1965 the National Centre for Scientific Research (CNIC) was created to carry out research in several fields, especially in the biological sciences. Most of its work is basic research, and it enjoys close associations with the various institutions and with the University of Havana. But although a few coordinating bodies were established—Councils of Agricultural Research, Sugar Research, Geology and Geophysics Research and so on—there was still no central directing body for science and technology. By 1974 the Cubans felt that they had a 'critical mass' of personnel and resources oriented towards research and development and that their socio-economic development was solid enough as a base for further work.

Camera Press

There was good reason for this. The investment in the universities in the 1960s began to bear fruit in the 1970s with a growing volume of research and increasing manpower. There are now more than one hundred basic research centres of varying size including research institutes, experimental stations and specialised laboratories, in which there are over 21,000 technical workers (about 20% of them university graduates); expenditure in 1975 on the basic research centres was $75 million. In 1957 there were an estimated 4,000 engineers and scientists and 5,000 middle-level technicians; in 1975 there were some 30,000 university graduates, about half of them scientists and technologists. University enrolment has grown from 15,000 (1959) to 30,000 (1970) to 83,000 (1975); the plan envisages 140,000 in higher education by 1980. In 1974 the breakdown by disciplines was:

Science and technology	52.8%
Agriculture	16.3%
Medicine	18.3%
Education	1.8%
Economics	7.0%
Social sciences	3.8%

In 1958 only 11% of the students were enrolled in science and technology. According to Cuban figures, there are 20 graduates and technicians per thousand of population. This means there are some 170,000 technicians in the country.

Highest priority

The Cubans have given education the highest priority, spending $874.6 million in 1975. The 1976–80 plan provides for 1.7 million in primary school in 1980, and 1 million in secondary school. There are four universities, and in the different provinces there are also 'university colleges' which are attached to one of the universities. 'University units' are centres of production, services and research where workers can carry out productive activities and take classes. University research is to a great extent carried out in teaching departments as an integral part of the students' science and technology training and the education of the staff. Some faculties have developed centres around specific topics, where teachers are assisted by researchers working in nearby schools and where postgraduates are trained. Some centres, for example the Centre for Digital Research and the Institute of Animal Science, do only research and postgraduate training; this type of centre is not directly dependent on the faculty or schools, and aims to train quality personnel and develop research.

With such advances, it was by 1974 time for more changes. In June of that year the government decided to establish a National Council of Science and Technology (CNCT) to manage the country's science and technology policy. Central management was deemed necessary to avoid publication, reduce cost, manage international collaboration and to coordinate the work of the various institutes with socio-economic development. Indeed, in establishing CNCT it was explicitly stated that a national science policy was a political not a technical decision.

CNCT was set up as an organ of the Council of Ministers with its President being the Vice-Premier of Education, Science and Culture. One of its vice-presidents was the President of the Academy of Sciences. The immediate task of CNCT was to draw up the national science and technology policy; once this was approved by the Council of Ministers, it was expected to control the execution of the plan and to propose practical application of the results obtained. The CNCT itself, which did not administer any research and development centre, had three main parts:

1. Presidential Council (President, Vice-Presidents, Secretary General and Directors.)
2. Advisory Committee (Members of the presidential council; well known scientists from different organisations and institutions; technical ministers and or vice-ministers concerned with research sectors and sub-sectors of research departments in universities; directors of the major research institutions.)
3. Scientific councils (Set up according to the nature and needs of the managing bodies, they are intended to bring together the most famous specialists in the relevant discipline independently of the organisations where they usually work.)

Mahindra Naraine is a Nature *Travelling Scholarship holder.*

Close collaboration with the Central Planning Authority (JUCE-PLAN) and with other bodies was necessary to achieve proper integration of science and technological plans with the socio-economic and cultural development of the country and to ensure that the science and technology plan would be one of the categories of the national economic plan. The 1976–80 economic plan was approved at the first Congress of the Cuban Communist Party in December 1975, and has three aims: to increase and diversify agricultural production to make the country self sufficient in food; to increase industrialisation; and to increase the production of sugar and nickel to pay for imports.

In agriculture the main areas of expansion will be rice, vegetables, citrus, poultry, fisheries and livestock. Industrial production will be increased in all areas, particularly fertilisers, steel, cement, paper and agricultural machinery. It is planned to produce about 600 cane harvesters a year from a Cuban design; this will reduce the workforce in the sector from about 370,000 to 50,000 by 1980. A nuclear reactor with capacity 880 MW will be built with Soviet assistance; in 1975 Cuban electrical generating capacity was 6.5×10^{12}W (about 700 kWh per inhabitant) but this is expected to increase by 35% over the next five years.

In 1959 sugar constituted 80% of Cuban exports and it held a similar position in 1970. In the future it is expected that the extensive Cuban nickel deposits will take over the role of main exchange earner, hence the 300% proposed expansion in nickel production.

CNCT plan

The CNCT drew up a plan for 1976–80 to link up with the national economic plan, slowly integrating indigenous research with technology transfer. Technology transfer is considered by Cubans to be indispensable to rapid economic development, but for it to be effective it must be adapted to local conditions and that means a large research and development base is essential. The CNCT plan focuses on the exploitation of Cuba's extensive laterite deposits; the application of nuclear technology and solar energy; the development of the electronics industry (to produce 100,000 television sets and 300,000 radios per year) and the development of computing and information systems (Cuban designed mini-computers are now being manufactured with Japanese components—under a Soviet–Cuban agreement, Cuba will provide the Comecon countries with certain components); the use of local products; and agriculture,

Cuban chronicle

Over the past hundred years Cuba has undergone three major transformations, and the development of its science and technology policy has tended to reflect this historical development.

The second half of the nineteenth century, ending with the first US intervention from 1898–1902, coincided with the rise of Cuban national consciousness and the struggle against Spanish colonialism. The first Cuban Academy of Sciences was founded in 1860, immediately prior to the Ten Years War, by about thirty European-trained academics, many of whom made contributions to world science. Attempts to introduce scientific and technical methods to Cuban agriculture, then in a primitive state, were unsuccessful; colonial conditions meant the Academy was 'peripheralised', and new development stemmed from technology transfers rather than indigenous sciences. By 1895 there were 1,186 students in institutions of secondary education—0.7 per thousand of population; the subjects studied were mainly Greek, Latin and rhetoric.

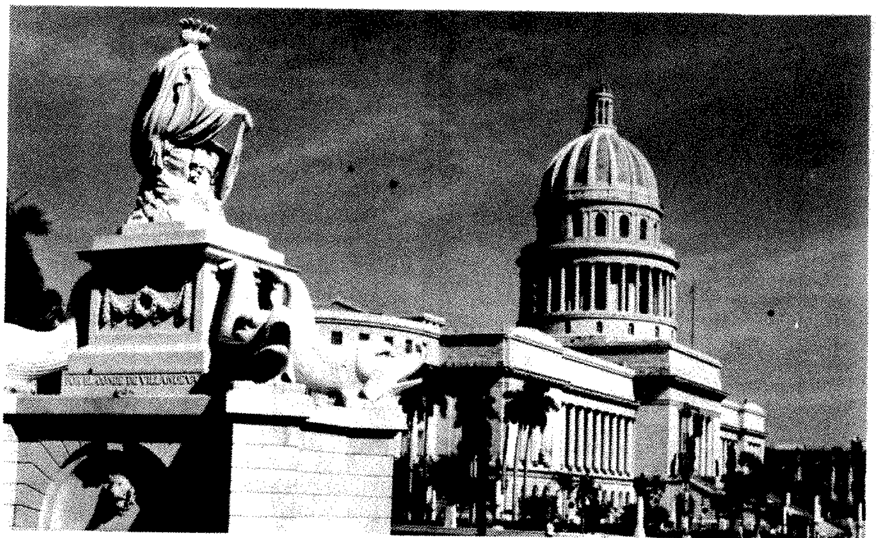
Cubans view the period beginning in 1902 and ending in 1958 as "the period of the neo-colonial republic marked by the presence of American imperialism." Local scientific activity was minimal and there were few research centres. The Academy of Sciences suffered a slow decline: by 1959 its yearly state budget was $600 and it did not possess a librarian. It was attached to the Ministry of Justice, while the Geographical Society of Cuba fell under the Ministry of State and the National Observatory was part of the Ministry of Sea and War. By 1958 15,000 students were enrolled in higher education, with 11% studying science and technology. About 60,000 students were in secondary education, representing about 10 per thousand of population. American missions in 1937 and 1950 commented on the paucity of technicians, the scientific and technological backwardness of the country and especially in the sugar industry, and the lack of facilities for research at the University of Havana.

The period was one of great political instability and culminated in the Batista dictatorship. The plantation economy, dependent on sugar for more than 80% of exports, was heavily reliant upon the US economy both in terms of trade and direct investment. The urban/rural dualism intensified, and by 1958 Cuba had half a million unemployed and two million illiterates and semi-literates in a population of 6.5 million. The period is seen as one of increasing cultural domination with continual attempts to belittle Cuban achievements. The example is cited of the recognition given to the American Dr Walter Reed as the discoverer of the carrier of yellow fever; in Cuba the Cuban Academician Dr Carlos Finlay is considered to have deciphered the problem.

The successful revolution of Fidel Castro and his followers in 1959 marked the start of Cuba's third period. Influenced by Soviet industrialisation, Castro and particularly Ché Guevara felt that a similar programme was necessary for the Cuban revolution to succeed. Science and technology were therefore recognised as critical factors in social and economic development, and in spite of a critical resource shortage, human and material resources were allocated for the creation of research centres to meet the requirements of the development plan.

The development plan which emerged for 1961–63 followed eighteen months characterised no less by chaos and government measures to gain control over all aspects of Cuban society, than by a programme of agrarian reform and a campaign to eradicate illiteracy. It was drawn up by Guevara and was intended to transform the Cuban economy from an agricultural to an industrial structure. It was expected to accelerate development on many fronts by means of import substitutions with emphasis on heavy industry. The programme exceeded Cuba's technical, administrative and resource capabilities; it ended as a failure.

The second growth strategy from 1964–75 reoriented previous plais, with their emphasis on agriculture, to centre on sugar and exports. Industrialisation remained the long term objective, but it was to be a gradual process with immediate expansion on a few fronts, such as cement manufacture, fertilisers and steel. Consequently, the science and technology infrastructure continued to expand, particularly in the training of personnel and in the establishment of research centres (see main story).



Cuba's Academy of Sciences, formerly the State Capitol

Barnaby's

livestock and fisheries. Over 100 problem areas have been identified for research and development activity.

Under the most recent changes, however, the National Scientific and Technological Council (CNCT) has disappeared. Its duties have been taken over by the State Committee for Science and Technology (CECT), whose head is a member of the Council of Ministers. This committee is the agency in charge of directing, coordinating and supervising the implementation of state and government policy in science and technology. It has to advise the government, prepare science policy, supervise research, establish research centres, and manage the science and technology information system.

The Academy of Sciences is now classed as an institute that is a central state agency, but its director will not be a member of the Council of Ministers. It has been charged with the drawing up, supervision and implementation of basic research and with being the link with foreign organisation. The various other technical ministries, covering, for example, the chemical industry, and mines and geology, will continue to have their own laboratories and do their own industrially oriented research. The work of all such ministries, however, will be coordinated by the CECT, which will also link up with the Academy of Sciences, the Ministry of Higher Education and the Ministry of Economic Collaboration.

Growing role

Cubas' international role is now growing; it is unusual to find a country so little endowed with natural resources such a large source of aid. Cuba's aid essentially comes from the technical expertise that is the result of its massive investment in scientific and technological education. The success has been little short of phenomenal, and it is estimated that there are more experts in the developing countries from Cuba than from any other country. But it is well known that Cuba has not achieved this by its own means. Since 1960 it has been drawn into the Soviet orbit; in 1970 the Soviet–Cuban Commission for Economic, Scientific and Technical Cooperation was formed, and in 1972 Cuba joined Comecon. Cuban development has been underwritten by the Soviets to the estimated sum of $5 billion since 1959. The full contribution of the Comecon countries is hard to assess, for apart from credits they provided expertise in the early years and also trained Cuban personnel. In 1969 as much as 20% of the scientific and technical staff engaged in research and development in Cuba were foreign but this manpower assistance declined as the Cuban investments in education began to produce results around 1970.

An important instrument in Cuba's new international role is the State Committee for Economic Collaboration (formerly the National Commission for Economic, Scientific and Technical Collaboration). In coordination with the State Committee for Science and Technology, it plans and administers foreign technical aid. As the relentless industrialisation drive continues, Cuba's voice is growing more important in the 'North–South' dialogue. Along with India and Yugoslavia she has been one of the leading advocates of greater trade between the underdeveloped countries. For a country that in the next decade expects to be the most industrialised of that group, it sounds like good business. Mexico and Cuba have already designed sugar mills and equipment for sale to the developing nations.

How far Cuba will be able to continue this programme and supply these countries is uncertain. What is certain is that a massive investment in science and technology has meant great political and economic gains. Castro was indeed prophetic: "The future of this country," he said in 1960, "must be the future of men of science." ☐

USA

Feasible, sound and attractive

A new report on the prospects for solar energy was published last week. Colin Norman reports from Washington

GIVEN sufficient political and economic support, solar energy technologies could supply as much as 40% of the world's energy needs by the turn of the century, and a startling 75% by the year 2025, according to a report published last week by the Worldwatch Institute, a small think-tank concerned with global problems. Such a major shift from fossil fuels to renewable energy resources "would require an unprecendented worldwide commitment of resources and talent", but the social and economic benefits "would far outweigh the costs and difficulties", claims Denis Hayes, who wrote the report[*].

Though a multitude of enthusiastic articles and studies have been written in the past few years to extol the virtues of solar power, the worldwatch report is already attracting considerable attention. For one thing, it was published while the Carter Administration was in the midst of putting together a long-awaited energy policy for the United States, a policy which is expected to place increased emphasis on renewable energy resources. It also breaks new ground in analysing the worldwide potential for solar power, while most other studies have concentrated on solar prospects in a single country. And its upbeat conclusions are also tempered by some realism about the political obstacles along the road to a solar powered world.

Hayes begins by noting that a transition from oil and gas to alternative power sources is inevitable, given the fact that production of oil and gas is expected to peak in the 1980s and that the price of those fuels is already beginning to increase by leaps and bounds. He argues that a switch to coal to provide energy needs over the next 50 years would result in "an absolutely intractable problem" of massive increases in atmospheric carbon dioxide, that a switch to nuclear power would require building so many nuclear reactors and recycling so much plutonium that "such a prospect cannot sanely be greeted with equanimity", and that fusion power is a long distance, unproven technology. That leaves the solar options, which Hayes defines as wind, falling water, biomass and direct sunlight.

Though Hayes is quick to acknowledge that most solar technologies are hard put to compete economically with conventional fuels at current prices, he argues that many alternative power sources have environmental costs and hidden subisidies which are not usually included in economic comparisons. As those costs are not internalised and as oil and gas prices spiral upwards, solar energy will become increasingly attractive, Hayes suggests.

Straightforward comparisons between solar power and conventional fuels also neglect an important factor: solar energy is not just more of the same. "Most energy decisions are based on the naive assumption that competing sources are neutral and interchangeable", Hayes notes, but solar technologies offer a highly decentralised and flexible power source which, if widely used, would result in a very different world from one powered chiefly by large central generating stations running on coal or nuclear fission. Solar technologies, Hayes argues, "are more compatible than centralised technologies with social equity, freedom and cultural pluralism".

---

[*] *Energy: The Solar Prospect* (Worldwatch Institute, 1776 Mass Avenue NW, Washington DC 20036, $2).

Hayes's basic message, therefore, is that a transition to a solar era "would be technically feasible, economically sound, and environmentally attractive". Furthermore, "the most intriguing aspect of a solar transition might lie in its social and political ramifications". A constant refrain running through Hayes's study is that many relatively unsophisticated solar technologies are already sufficiently developed to be put to use, either alone or in tandem.

On solar heating and cooling, for example, he argues that more attention should be paid to the thermodynamic efficiency of energy production and use, suggesting that it is "surely the height of thermodynamic foolishness" to use a nuclear reactor operating at thousands of degrees to run a water heater to heat bath water to 30 degrees. About a third of the energy now used in the world provides low-temperature heat, which solar collectors can already achieve in many parts of the world, Hayes claims. Moreover, if the lifetime fuels costs are properly counted in economic comparisons, he contends that solar heaters are already able to compete with conventional fuels.

Another promising renewable energy source is small hydroelectric plants which could easily be constructed to serve small villages. Even in the United States, Hayes reckons, there may be a as many as 50,000 potential sites available for hydropower plants as small as half a megawatt. There is also a large and relatively untapped source of energy from the production of methane from animal wastes, ethanol from fermenting plant wastes, and low-grade heat from biomass, Hayes suggests. A start has, however, been made on some of those technologies, particularly in India and China which are operating a substantial number of methane plants, and Brazil and Australia, where fermentation plants running on sugar cane and eucalyptus wastes are already in production.

As for more sophisticated uses of solar energy, such as large-scale generation of electricity, Hayes argues that although massive solar generating plants would hold considerable environmental advantages over conventional and nuclear power stations, they would also carry some of the disadvantages of inefficiency and centralisation. "A sensible energy strategy demands more than the simple-minded substitution of sunlight for uranium," he suggests. Photovoltaic cells, which convert sunlight directly to electricity, have the advantage of providing a decentralised power source which could be used in tandem with other small-scale generators such as windmills, Hayes notes, suggesting that photovoltaics "may offer the most exciting solar electric prospect".

Unfortunately, however, they also have a major disadvantage: their cost is at present prohibitive. Nevertheless, Hayes is optimistic. He notes in his study that the cost of photovoltaic cells has dropped from $200,000 per peak kilowatt in 1959 to about $13,000 today. If the trend continues, and if it is helped by economies of scale, Hayes reckons that the cost may drop to as low as $500 per kilowatt by 1985.

If the transition to a solar era is not made during the next 50 years, Hayes argues, "the roadblocks will have been political, not technical". With massive investments already made in coal and nuclear technologies, and a large gap between future energy supply and demand generally perceived by energy planners, the political roadblocks are formidable, however. President Carter's forthcoming energy policy, which is expected to be announced next week, is likely to provide a boost to both coal and light water reactors, though it is likely to pour some cold water on longer term nuclear plans. As for solar technologies and other renewable resources, it is expected to provide nothing of the support, and certainly nothing of the magnitude which Hayes calls for. ☐

Recombinant DNA bill proposed

THE Carter Administration last week finally proposed legislation to control all recombinant DNA experiments in the United States, after some three weeks of discussions between the Secretary of Health, Education and Welfare (HEW) and officials from the National Institutes of Health (NIH) and the White House. Although the final version of the bill conforms closely to a draft version proposed last month by an interagency task force, it differs in one key respect: it would allow state and local governments to establish controls on the research which are more stringent than the federal regulations.

The bill was formally introduced into the Senate last week by Senator Edward Kennedy, Chairman of the Senate Health Subcommittee which will handle the legislation. Kennedy made clear, however, that he doesn't necessarily agree with every word in the bill and in a statement he outlined a few reservations with the Administration's approach.

The bill would essentially require the Secretary of HEW to establish regulations to control recombinant DNA research in both public and private institutions. He would be required to issue interim regulations within 90 days and a final version within a year, after allowing suitable time for public comments and discussion. The interim regulations, at least, would probably be the guidelines issued last year by NIH. The bill would also require that all facilities housing recombinant DNA experiments be licensed by HEW.

There is also a provision in the bill which would empower HEW to send inspectors into laboratories the ensure that the regulations are being followed and violations could result in a fine of $5,000 per day. Particularly serious and wilful flouting of the rules could also result in a prison term, the bill states.

As for the provision allowing state and local governments to set stricter controls than the federal regulations, many scientists are now supporting federal legislation on the grounds that uniform national regulations would be preferable to a patchwork of local controls of varying stringency. The draft version of the Administration's bill would have accomplished that by simply making the federal controls paramount, but the final version would allow the states to add extra controls if they want to. According to Administration sources, the provision was changed so as not to throttle local debate over recombinant DNA but it also bows to the political reality that a move to pre-empt state and local control would be unlikely to be passed by Congress.

The focus of legislative activity has now shifted to Senator Kennedy's Health subcommittee, which held a public hearing last week. One provision which Kennedy may add to the bill is a requirement that the National Commission for the Protection of Human Subjects of Biomedical and Behavioural Research, which has been looking into a variety of biomedical issues for the past two years, be given the task of examining the long-term implications of genetic engineering.

Colin Norman

Gloom at the top

Details of Britain's Science Budget, were disclosed last week. Chris Sherwell reports

IF THERE is despondency in Britain's science community this week, no one should be surprised. There is gloom at the top. Details of the Science Budget given last week by the Advisory Board for the Research Councils (ABRC) covered allocations for the 1977–78 financial year just begun and guidelines for the four additional years to 1981–82. The figures are much as expected (see table), but then sliding down a curve is no more comfortable for being warned of it in advance, particularly when (as now) the low point remains invisible.

Outlining the trends, the ABRC chairman, Sir Frederick Stewart, said the 1977–78 Science Budget of nearly £249 million (1977 prices) represented a cut in real terms of more than 3% on the 1976–77 budget. The government's public expenditure White Paper published in February indicated a budget of £216 million for the year, but this was at 1976 prices. Both figures included an additional £6 million to cover the increased cost of post-graduate tuition fees in 1977–78, and this too tended to make the trend less steady than it actually was.

Discussing the guidelines, Sir Frederick drew on the White Paper's own emphasis on the provisional character of figures for the years 1980–81 and 1981–82 in describing them as "very provisional"; they were intended to provide each of the councils with a broad basis for planning. The guidelines did, however, represent a continuation of the protection of the "small and medium sciences" at the expense of high energy physics, astronomy and space.

Thus the Science Research Council (SRC) faces a 1.7% contraction annually, a cut which Sir Frederick said could amount to more than 20% over a five-year period with vexed problems like 'salary creep'—the consequence of maintaining ageing research staffs on graded incremental salary scales.

On the other hand, in line with the SRC's and the ABRC's previously announced intentions, support for engineering is to grow substantially, and is in fact the only part of the budget to show a marked increase. How much this increase will prove to be by the end of the period was uncertain, Sir Frederick said, but it "might amount to a 60% expansion". The SRC chairman, Sir Sam Edwards, stressed, however, that even a modest effort in favour of engineering would represent a large increase on the support that it received before. He was also quick to dismiss suggestions that the perceived need to support work 'relevant' to the country's industrial needs diluted the SRC's task of supporting basic research: the SRC's support for engineering, he insisted, was for basic research, just as it was in other fields.

Sir Sam described the reductions in support for big science as more serious than the figures suggested. Much of the SRC's expenditure went on international subscriptions, for example to CERN, and that meant that the effective decline in support for domestic activity might be more than 50%, not 20%. This, he said, would happen at a time when the pressure was on for Britain to participate fully rather than merely "tick over"; there were many projects which ought to be done "bigger, better and faster" than they were being done.

The position on international subscriptions clearly remains precarious. The SRC has the money to pay them this year, Sir Sam said, but if the pound collapsed again, "I don't know where we are"; the government had not given an open-ended commitment, and no bailing out could be guaranteed if that again proved necessary. As for the SRC's maintenance of a "minimum viable level of support" for big science—a concept outlined last year as the cuts really began to bite—Sir Sam confirmed that the big science community already believed that that level had been breached. The council's view, he indicated, was that it was extremely difficult to judge precisely what that level was.

Like the guidelines, the allocations of the 1977–78 budget reflect the policy of redeployment away from big science, though as usual the lion's share necessarily goes to SRC. Also given are figures for research commissioned by government departments under the Rothschild arrangements for applied research.

For the Agricultural Research Council (ARC) income from commissioned research, representing 55% of its total budget, will grow at 0.6%, but this will only contain the 'salary creep'. The Medical Research Council (MRC) faces more of a problem. As part of the general cuts in government expenditure the Department of Health has at short notice cut by 10% its commissioned research. The Natural Environment Research Council expects to have its funds maintained from the various departments (Agriculture, Industry, Energy, Environment), but anticipates cuts in the future. Against all this, Sir Frederick said that he saw no evidence that the spending departments were taking their funds elsewhere, a possibility Rothschild originally foresaw.

There is no doubt that the research councils face problems. Apart from the usual agonising difficulties of deciding priorities and, more notably, starting new projects, they agree that their main problem is nothing less than "keeping science alive" in Britain. In that they were echoing the views contained in the recent annual survey from the University Grants Committee (UGC), which with the research councils constitutes the Dual Support System for university research.

"We are deeply concerned", said the UGC, "about the deterioration of research capabilities in the universities . . . We will continue to watch the developing situation with anxiety". Those words might well have been repeated last week by the research councils for the whole of Britain's civil science effort. ☐

Science Budget: Allocation and Guidelines

	£ million[1] 1977–78	% Share	% p.a. 1978–79 to 1981–82
ARC	20.4	8.2	1.9
MRC	42.3	17.0	1.6

BRITAIN

● Unsurprisingly, yet another view of the energy problem was heard at last week's 'Energy in the 80s' conference organised by the Institute of Chemical Engineers in Middlesbrough. It came from L. G. Brookes of the UK Atomic Energy Authority (UKAEA) —speaking in his personal capacity, of course—and it was aimed at undermining the 'conventional' view.

The conventional view, said Brookes, argued that the OPEC oil price rises have been a good thing, by inducing thrift and providing an incentive to develop other alternative energies, so that reduced demand and promotion of coal, nuclear power and alternative energies will close the energy gap. According to Brookes, however, price rises are not the solution to the problem: "they are themselves the problem".

His argument is simple. High energy prices have affected the economy adversely. That has hit the rate of growth of electricity demand, upon which the rate of nuclear power installation depends. That in turn has severely reduced the rate of substitution of nuclear for fossil energy. "It follows", says Brookes, "that a reduction in energy prices (or at the very least their stabilisation) [is] our number one energy policy objective".

Brookes' leap of logic is based on his view that uranium, coal and Middle East oil are the only large sources of low cost fuel, that uranium, used in breeders, is a greater source than all others together, and that nuclear power is the cheapest, safest and cleanest way of producing electricity.

Those with problems accepting nuclear power will be quick to question the thinking behind such arguments. But there will be others who will find some of Brookes' additional conclusions controversial as well. For example: high oil prices have actually lowered "the level of economic high spirits necessary for major investment in new energy sources", and her current "flirtation" with wave and solar power, which arises "to some extent from a misdiagnosis of the problem", may do harm if it is seen as an alternative to nuclear power. There is no reason to take it for granted, he adds, that the days of cheap energy are gone forever.

The Department of Energy's view is different, naturally. Last week it announced that the £1 million feasibility study of wave power it unveiled last year is to receive a boost following the encouraging developments experienced so far. Now a total of £2.5 million will be spent by October 1978, with the extra money going mainly to larger-scale studies.

● Smokers in Britain who have felt under increasing pressure over the past couple of years will have noticed the recent period of fits and starts experienced by Britain's cigarette industry. Measures to reduce the health hazard from smoking announced at the beginning of last month included a strengthening of the warning on packets, moves to extend public no-smoking areas and curb advertising, and the prospect of an end to high tar brands.

Close control of tobacco substitutes and additives according to guidelines from the Independent Scientific Committee on Smoking and Health (the Hunter Committee) was also sought, and at the end of the month the government gave the go-ahead to part-substitute cigarettes, the first of which may be on sale in July, subject to agreement on long term health studies. The Hunter Committee said it had decided to raise no objection to the carefully controlled use of two cellulose-based substitutes, Cytrel, made by Celanese Corp., and New Smoking Material (NSM), made jointly by ICI and Imperial Tobacco. The cigarettes will be mixed with about 25% tobacco, will carry the government health warning and will be no cheaper.

The price of cigarettes has since gone up, and the House of Commons Expenditure Committee on Preventive Medicine has recommended legislation against advertising and advocated dearer prices still, stronger health warnings and more non-smoking accommodation.

● The National Radiological Protection Board (NRPB), which last month published a review of its recent work over the three years 1974–76 (*The Work of the NRPB 1974–76*, HMSO, £2), published a paper last week on the radiation exposure of the British population (*Fallout in rainwater and airborne dust-levels in the UK for 1975*, NRPB-R49, HMSO, 50p). Based on the analysis for fission products and plutonium isotopes of rainwater and airborne dust collected during 1975, the results show average depositions of ^{137}Cs and ^{90}Sr in rain were less than 2% of peak values recorded in 1963 following a period of heavy weapons testing. Fallout during 1975 will contribute another 1% to the total dose people will receive.

● The departure of Francis Crick from Cambridge to the Salk Institute has directed widespread attention at academic salaries and the position of those who earn money abroad. So what are the circumstances of those at the top of the ladder?

Professors and their counterparts in MRC units are paid a minimum of £8,016 in 1976–77. There is no upper limit in universities, provided each university's average salary does not exceed £9,489. The MRC's Special Appointments Grade tops out at £10,200, though higher salaries are paid in respect of special service.

Five years ago the minimum was £5,376 and the professorial average £6,528; the cost of living index has since risen by at least 75%, while salaries have risen only 45% to 50%. Though everyone in this salary range has suffered substantial setbacks in real income, university and research council employees have suffered more than most. Many have been able to supplement their income by doing short periods of work abroad. Until 1974, this income was not taxed unless brought into the country, but in the past three years those who work abroad in a wholly separate job with duties entirely performed outside the country have been allowed only a 25% tax exemption of their earnings, regardless of where the money is kept.

The recent UK Budget has liberalised the tax position for many who work overseas under tax conditions less favourable than this, but has not made any further concessions to the category which includes visiting academics. The level of taxation on the 75% taxable will depend, of course, on the total sums earned in a year, but would typically run at a level from 45% if total taxable income in the year (including UK salary) was between £7,000 and £8,000, up to 83% for over £21,000.

IN BRIEF

Windscale inquiry dates

Mr Justice Parker, who was appointed along with two assessors to conduct the inquiry into British Nuclear Fuels Ltd's plans for an oxide fuel reprocessing plant at Windscale, is to conduct an informal preliminary meeting open to the public and press to discuss the programme and procedure for the inquiry. The aim of the meeting, on 17 May in Whitehaven, Cumbria, is to allow all concerned parties to make representations on these matters ahead of the main inquiry, which opens on 14 June also in Whitehaven.

Them and us

The difference in attitude towards foreigners between the general manager of R&D at ICI and the Chief Scientist at the Department of Industry (DoI) is that the former thinks of them as 'us' and the latter as 'them'. Duncan Davies, who made the transition from one to the other when he left ICI at the end of March, last week expressed his regrets at losing some of his former international involvement. Talking of British industry, he said that the 'entrance fee' for innovations—the initial investment to develop an idea into a marketable product—had increased by several orders of magnitude over the past twenty years. To ensure that it is recovered, better planning was needed at the initial stages of a project. Highly trained scientists and engineers, he said, should also be trained to judge the potential of an idea in the marketing as well as the scientific world before committing industry to a large investment which it might otherwise lose.

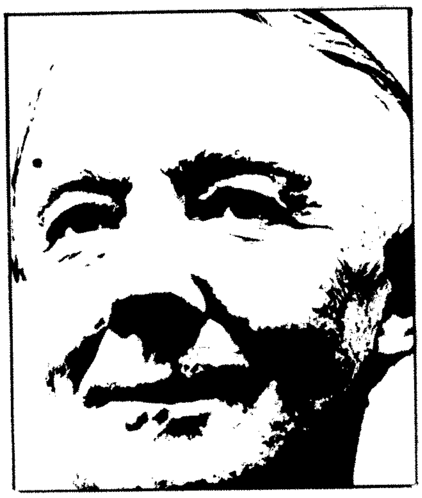
RGO exhibition

The Royal Greenwich Observatory at Herstmonceux has put together, out of its own resources, a small exhibition on the castle and its environment and the work done by the observatory. The castle already has numerous visitors to the Isaac Newton Telescope and to the spacious grounds; they will now be able to visit the exhibition as well.

Chemical hazards report

A report published recently by the Chemical Industries Association's Safety and Health Council (CISHEC) provides the industry with details of a technique to combat potential hazards in existing and new large-scale chemical processes. The technique, known as a Hazard and Operability Study, involves systematic study of every part of the proposed process and speculative consideration of the consequences of every possible deviation from the norm. Remedial action for every potential hazard is then noted. (*A Guide to Hazard and Operability Studies,* CISHEC, £4.50.)

Publish or perish



KENNETH MELLANBY

MANKIND has always suffered from disasters. The archetypal catastrophe was the flood, described in the Hebrew scriptures and in various middle eastern legends. Only eight individuals out of the whole human population were said to have survived to repopulate the globe with their progeny and that of the other animals saved from drowning in Noah's ark. Then in the second millenium BC the Aegean island of Santorini exploded, burying its cities in debris, and causing a tidal wave which may have ended the Minoan civilisation in Crete. This view was held by the leading Greek archaeologist, Professor Spirodon Marinatos. Shortly before his death in 1975 I heard him speak of his studies and demonstrate his excavations on Santorini. With all the signs of disaster around him he communicated his enthusiasm even when addressing a largely English-speaking audience in Greek; almost the only words I actually understood were *καταστροφη* and *κατακλασμα*.

No one else was left to organise an expedition to help in Noah and his family's rehabilitation, and the more fortunate populations on the shores of the Mediterranean were not in a position to feed and house any survivors in Crete. Today, however, with improved communications, the rest of the world soon knows of disasters in remote corners of the globe: funds are raised and expeditions with food, medical supplies and means to improvise shelter are rapidly dispatched to try to reduce the misery of the victims. It is sometimes ironical to note that there may for generations have been chronic shortages of all the necessities, with thousands of preventable deaths each year, in these same areas, and that world opinion has remained unmoved until a spectacular flood or earthquake has occurred. Then financial and material aid has poured in, making at least some of the population (perhaps the least deserving members) richer than ever before.

Aid for the victims of disasters has not always been appropriate in kind, nor has it always been administered efficiently. Various international agencies have built up a corpus of information, but this is not readily available to those wishing to help. For this reason the London Technical Group has launched a new quarterly *Disasters: The International Journal of Disaster Studies and Practice,* aimed at educating scientists and relief workers. It says it will describe both successful and unsuccessful experiments in disaster relief.

The first number reports on a UNESCO conference on the assessment and mitigation of earthquake risk. There are articles on the drought in the Sahel and on emergency shelters. Various useful equipment is described. Perhaps the most interesting contribution is a letter based on experience of the Skopje earthquake in 1963 in Yugoslavia, which shows how the local population, with the materials already available, produced effective makeshift shelters long before expensive and inferior emergency houses could be shipped from abroad. This is one instance of how aid can be misused due to the ignorance of the well meaning. If future issues can keep up this standard, the journal deserves to succeed.

Our attitude to disasters, which we share with the insurance companies, has curious theological implications. A colleague, a member of his parochial church council, was active and successful in raising money to repair a mediaeval church whose roof suffered in the gales of January 1976. At the end of the year, surveying the relatively favourable balance sheet, he informed his somewhat surprised rector that everything should be satisfactory for the next year or two, "unless we suffered from another act of God".

Oklo today

Sir,—It is obviously of great interest to trace the fate of the fission products from the natural nuclear reactor at the Oklo River, Gabon (17 March, page 206), but if parallels are to be drawn with present day reactors and radioactive wastes, then one further fact needs to be stressed, namely that today's world is seething with complex living organisms. 1.8×10^9 years ago there were, in all probability, only comparatively simple organisms.

Today's organisms have very considerable powers of dispersal so that any radioactive chemical which enters one organism may be transported a considerable distance as it travels through the food chain; and higher organisms (mammals for example) are 1,000 times more sensitive to radiation than are the simpler forms of life (such as bacteria) which might well have existed at Oklo. To argue that since we, as living organisms, survived Oklo we can also survive comparable releases of radioactivity today is dangerously misleading. Of course life will survive the next few hundred years, but the question is at what cost to the particular forms of life that we consider to be important such as our own species.

Scientists as administrators

Sir,—Your issue of 27 January, 1977 carries two articles which are complementary. The first is abstracted from Sir Hermann Bondi's broadcast and points out the very limited movement of scientists to administrative posts in the Civil Service and in industry in general; the second, by Kenneth Mellanby, provides the apparent paradox by emphasising that, in war-time, academics immediately turned to administrative tasks with great success. Mellanby goes on to ask why academics do not do this now.

In war, there was one clear objective—the enemy. The desired end was agreed by all, and a constant beacon to steer by. Not so now when national goals are confused and form the subject of bitter political wrangling and power-seeking. Yet, if, for example, the intensive cultivation of the Highlands of Scotland was essential for national survival, I have not the slightest doubt that the scientific ability needed to do this would flow as readily and effectively as it did to defeat the Nazis.

Sir Hermann points out that scientists as administrators must be seen to be badly needed. Rightly or wrongly the scientist is still often made to feel a poor relation of the arts man in respect of administrative ability, though not in organisations such as Unilever and ICI whose effectiveness as innovators is remarkable.

This will not be changed simply by altering the structures of science courses, but by a positive effort to encourage scientists to move to administration. I would like to see advertisements for administrators, stating that applicants with a scientific and technological background are preferred, and would be given the appropriate training if needed. After all, professors of science and technology and the heads of departments in government scientific institutes began life as rather shy, young scientists: most are now capable administrators and few would doubt their capacity for argument—written and spoken—sharpened and tempered as it is by the ceaseless battle with well-meaning but uncomprehending, non-scientific administrators.

Cutting out abbreviations

Sir,—Adrian Smith's suggestion (10 February, page 492) that abbreviated titles of periodicals be replaced by full and accurate citations, will have the sympathy of authors, editors and secretaries. This proposal has already been tested in practice. The *British Medical Journal* stopped abbreviating titles in April 1969. A working party set up in 1968 by a Conference of Medical Editors[1] "strongly recommended all journals to follow suit: a majority of (medical) editors agreed to do so". The working party also reported that with full citations "the increase in type area is maximally 2% and usually much less". The editors of the *British Medical Journal* also reported that "the saving in editorial time is enormous".

When the effective use of public money on scientific research is increasingly coming under close scrutiny, any time spent by authors and indeed editors, themselves very often active in research, on such a mundane and unproductive task must be seriously questioned. If any economies result from the present practice, they must only be reflected in the balance sheets of publishing companies.

Stamps of scientific interest

The British Post Office marked the centenary of the Royal Institute of Chemistry by issuing a set of four multicoloured stamps last month, each featuring a Nobel prize-winning development.

The two shown, at 8½p and 11p, commemorate Professor Sir Derek Barton's work on conformational analysis and the development of partition chromatography by Professor A. J. P. Martin and R. L. M. Synge. They depict the central part of the chemical structure of a steroid against a background of pharmaceutical products and instruments; and a graph, showing the different amounts of substances in a complex mixture separated by partition chromatography superimposed on the kind of pattern produced by the technique when used on paper.

The other two stamps, at 10p and 13p, commemorate the work of Sir Norman Haworth, which resulted in the first synthetic vitamin identical to that occurring in natural citrus fruits, and the work of Professors Sir William and Sir Lawrence Bragg, the father and son who developed crystallography.

Australia last year issued a set of four 18c stamps featuring famous Australian scientists, three of whom ironically were born in England. Sir Thomas Laby (1880–1946) did much of his research on the possible uses of radium in combating cancer. Professor Griffith Taylor (1880–1963) joined the Commonwealth Weather Service in 1910 as a physiographer and then joined Scott's Antarctic expedition.

The other stamps depict the ornithologist John Gould (1804–81), regarded as the father of Australian bird study, and the anthropologist, Sir Baldwin Spencer (1860–1929), who studied the tribal customs of Australian aborigines.

Transferable drug resistance in the gonococcus

from J. R. Saunders

GONORRHOEA is currently the most prevalent human communicable bacterial disease. Despite the emergence of strains of the causative organism *Neisseria gonorrhoeae* (the gonococcus) with increasing resistance to penicillin, single high doses of this antibiotic have generally proved effective. The discovery last year of infections in Britain, the Far East and the USA which were refractory to this regimen has caused understandable alarm amongst clinicians (see for example, *Center for Disease Control Morbidity and Mortality Weekly Report* **25**, 261; 1976; Percival *et al.*, *Lancet* **ii**, 1379; 1976; Phillips *Lancet* **ii**, 656; 1976), and the current policy of treating gonorrhoea 'blind' with penicillin has therefore been questioned. The culprits for these recent outbreaks are highly penicillin-resistant gonococci producing the TEM β-lactamase (penicillinase). This enzyme is specified by the widely dispersed transposon A (TnA) and its acquisition by *N. gonorrhoeae* had been widely predicted. TnA is commonly located on R plasmids in the Enterobacteriaceae, *Pseudomonas aeruginosa* and *Haemophilus influenzae* and it seems probable that gonococci have acquired it by contact with one of these organisms.

Almost all gonococci so far studied contain a plasmid of about 2.5 Mdal which has no known function (see for example Mayer *et al. Infect. Immun.* **10**, 1974; Palchaudhuri *et al. Infect Immun.* **11**, 114; 1975). Some gonococcal strains contain an additional plasmid of about 25 Mdal (Stiffler *et al. J. Bact.* **122**, 1293; 1975). But so far all known antibiotic resistances in *N. gonorrhoeae* have been shown to be determined by chromosomal genes. Two groups working independently, Roberts and Falkow (this issue of *Nature*, page 630) and B. I. Eisenstein *et al.* (*Science* **195**, 998; 1977) now show that at least two species of β-lactamase plasmid exist in gonococci, one, from Far East strains, of about 4.4 Mdal, and one, from British strains, of about 3.2 Mdal, in addition to the resident cryptic plasmids. The origin of these resistance plasmids is not yet clear. They may have been received in entirety from other Gram negative bacteria, in particular from *H. influenzae*, which contains similar β-lactamase plasmids (de Graaf *et al. J. Bact.* **126**, 439; 1976). Alternatively they may have arisen by transposition of TnA to resident gonococcal plasmids. The 'donors' of TnA in this case could have been R plasmids which are capable of entering but not subsequently maintaining themselves in *N. gonorrhoeae*. Whatever mechanism is involved, the different plasmid complements of the British and Far East strains suggest that the TEM β-lactamase gene has been acquired by *N. gonorrhoeae* on at least two separate occasions. The 4.4 Mdal β-lactamase plasmid is widely distributed amongst gonococcal strains known to be different on the basis of their nutritional requirements (auxotypes). This implies that considerable interstrain transfer has occurred. It is well known that chromosomal antibiotic resistance markers can be transferred between gonococci by transformation, which is the only mechanism of genetic exchange so far reported in *N. gonorrhoeae*. However, Roberts and Falkow have found that covalently closed circular DNA of either type of β-lactamase plasmid cannot transform *N. gonorrhoeae*. This indicates that transformation plays no significant part in the dissemination between strains of the β-lactamase plasmids.

Roberts and Falkow, and Eisenstein *et al.* have now shown that the 4.4 Mdal β-lactamase plasmid can be transferred by conjugation to other gonococci, to *Neisseria flava* and to *Escherichia coli*. This plasmid is, however, too small to encode sex factor activity itself and only those strains which also carry the 25 Mdal cryptic plasmid can act as donors. The β-lactamase producing strains isolated in the UK, which all lack this larger plasmid, cannot therefore donate penicillin resistance to other bacteria. The 25 Mdal plasmid is thus apparently acting as a gonococcal sex factor and it is of interest that this plasmid has not yet been found in recipient bacteria which have acquired the β-lactamase plasmid from donor strains. This suggests that covalent linkage between the two plasmids is not necessary for transfer but it is not yet clear whether the gonococcal sex factor is totally incapable of transferring itself to other bacteria. However, similar mobilisation of non-self-transmissible plasmids by transfer factors is well documented in the Enterobacteriaceae. It will be of great interest to determine the molecular and genetic properties of this sex factor and whether it is of gonococcal origin.

The discovery of sex factor activity in the gonococcus has serious clinical and epidemiological implications. First, it increases the probability that more strains of *N. gonorrhoeae* will acquire genes for resistance to penicillins and other drugs. It also makes more likely the transfer of resistance genes to a close relative of the gonococcus, *N. meningitidis*, the causative agent of epidemic meningitis. Meningitis is more likely to be fatal than gonorrhoea and the situation is complicated by the fact that *N. meningitidis* is carried without ill effect in the throats of many healthy individuals. Transfer of β-lactamase genes to this organism could occur either directly from *N. gonorrhoeae*, from enteric bacteria, or from *H. influenzae*, also a common inhabitant of human throats and which can cause disease. Furthermore, *H. influenzae* has in recent years acquired both the TEM β-lactamase and the ability to conjugate. In contrast, however, the gonococcal sex factor could benefit research workers by providing a means of genetic transfer in addition to transformation for analysing the genetic determinants of pathogenicity in *N. gonorrhoeae*.

There is obviously a certain irony in the possession of sexuality by *N. gonorrhoeae*. If the gonococcal sex factor determines the synthesis of sex pili, these should provide adsorption sites on donor cells for male-specific bacteriophages. The possession by gonococci of their own venereal pathogens would indeed be divine justice. □

New Uranian satellite belt

from David W. Hughes

On 10 March at about 21.00 universal time the planet Uranus passed across the star SAO 158687 in the constellation of Libra. Reports of this occultation have caused considerable excitement because not only was the star occulted by the planet but it was also occulted by a series of much smaller satellite objects that seem to be in an equatorial belt around the planet.

The occultation was first predicted by Gordon Taylor of the Royal Greenwich Observatory (*J. Br. astr. Assoc.* **83,** 352; 1973). No useful observations of an Uranian occultation had been made before and even for this one the occultation would only be visible from a small area of the Earth. Also Uranus would be about 40 times brighter than SAO 158687 which has a photographic magnitude of +10, so Taylor predicted that the observations would be extremely difficult and would need complex photoelectric equipment.

Occultation observations are important because they can provide data as to the size of the planet, its limb darkening and the extent and composition of its atmosphere. They also provide an accurate spot measurement of the planet's position which is extremely important when it comes to using celestial mechanics to calculate planetary perturbations.

The positions of Uranus, given in the Astronomical Ephemeris, and of the star SAO 158687, given in the Smithsonian catalogue, were carefully checked in January 1977 using photographic plates obtained with the 155-cm astrometric reflector at Flagstaff, Arizona. Franz, Wasserman, Seidelmann, Van Flandern and Marsden (*IAU Circ.* 3038/40) reported that the position of the star had to be corrected by +1.15 arc s in declination. Transit circle observations of Uranus indicated that its declination should also be corrected by −0.22 arc s. This meant that the occultation would not be visible everywhere that Uranus was above the horizon, but would only be seen in an area whose northern limit extended from equatorial Africa, across the Indian Ocean, somewhat north of Perth, Western Australia and then into daylight. There was an uncertainty of about ± 2,500 km in this northern limit caused by the uncertainty in the positions of the planet and star and an additional uncertainty of about 1,500 km due to the fact that the exact radius of Uranus is not known. Occultation would occur near 21 h 00 min UT and the duration would increase as one moved south.

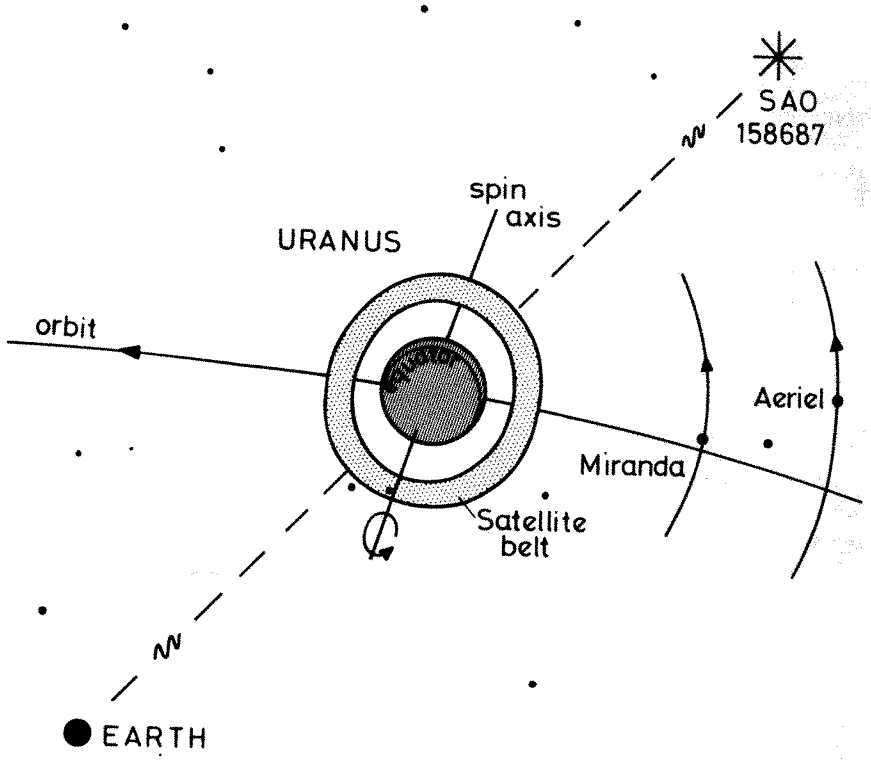

Fig. 1 A schematic diagram of Uranus and its newly discovered satellite belts at mid-occultation on 10 March, 1977. Miranda and Aeriel are the two innermost satellites, SAO 158687, the occulted star, is a 10th magnitude, K5 spectral type star in Libra. The equator of Uranus, the satellite belt and the orbital planes of Aeriel, Umbriel, Titania, Oberon and Miranda are all inclined at about 98° to the ecliptic plane of the Solar System.

On 10 March heavy rain prevented observations in the vicinity of Johannesburg; however astronomers on board the Gerald P. Kuiper Airborne Observatory flying across the southern Indian Ocean about 1,000 miles East of Kerguelen Island (long. 90E, lat. 50S) were more fortunate. The occultation lasted for about 25 min around 21 h 06 min UT. Dunham, Elliot and Mink, the Cornell University astronomers on the plane also, to their surprise, saw a series of secondary occultations that took place during an 8–9 min interval around 20 h 16 min UT and during a similar interval around 21 h 50 min. Bhattacharyya and Kuppuswamy (Indian Institute of Astrophysics) using the 102-cm reflector at Kavalur, Madras saw the secondary occultation start at 20 h 19 min 51 s and last for 8–9 s (they also observed that the star faded by 0.046 magnitude when it went behind the atmosphere of Uranus). Millis, Birch and Trout at the Perth Observatory, Western Australia saw the earlier of the two secondary occultations. All the groups independently concluded that these occultations were caused by satellites that are apparently part of a belt about 48,000 km from the centre of Uranus. This belt is shown schematically in Fig. 1. As Uranus travels along its orbit the left hand portion of the belt occults the star first then the planet occultation occurs. Finally the right hand belt occults.

Brian Marsden (Smithsonian Astrophysical Observatory) has used the times of occultation to compute the following details (*IAU Circ.* 3048, 3051). The belt is circular, in the plane of Uranus' equator, about 12,000 km wide and extends between 42,200 and 54,300 km from the centre of Uranus.

The fact that the times of the individual secondary occultations are remarkably symmetrical with respect to the Uranian occultation suggests that the occulting material is confined to specific narrow rings in the belt. The Kavalur observation seems to have been caused by a 100 km sized satellite near the outer edge of the belt.

Elliot, of the Centre for Radiophysics and Space Research, Cornell University, is continuing the detailed study of the occultation records. It might also be possible to observe the belts directly, although a very large telescope will be required as the brightest satellite is expected to have a magnitude of about 19. At the present opposition of Uranus the belts are between 3.5 and 4.0 arc s to the north and south of the planet and 2.7 to 3.1 arc s to the east and west. ☐

Engineering nitrogen fixation

from Andrew Johnston

> A conference entitled Genetic Engineering for Nitrogen Fixation, organised by Dr A. Hollaender, was held at Brookhaven National Laboratories, Upton, New York, on 13–17 March, 1977.

THE current interest in biological nitrogen fixation reflects the desire that an increased amount of the fixed N in crops should come from this source rather than from energy-expensive fertiliser. The aim of this meeting was to see whether such a goal might be achieved by genetic techniques. Most reports dealt with the status of current research in different aspects of nitrogen fixation, but attention was given to systems whose development might conceivably lead to an extension of the range of nitrogen-fixing organisms.

D. Helinski (University of California, San Diego) reviewed the methodology and uses of DNA cloning. He made the point that to date only the P-group R plasmids can be transferred to many bacteria of agronomic importance. However, their promiscuity and relatively large size make them unsuitable as cloning vehicles and he described methods by which the ability to replicate in a wide range of bacteria might be transferred to more appropriate vehicles.

Detailed mapping of nitrogen fixation (*nif*) genes has been caried out only in *Klebsiella pneumoniae*. C. Kennedy (ARC Unit of Nitrogen Fixation, Sussex) showed by transduction that *nif* genes fall into two closely linked clusters separated by a 'silent' region. Complementation tests have defined a new *nif* gene (*nifL*) which has the attributes of a controlling gene since the mutant is partially dominant and synthesises no nitrogenase components. F. Ausubel (Harvard University) reported that the *nif* cluster proximal to *hisD* could be cloned on the plasmid pMB9.

Turning to the genetics of other nitrogen-fixing bacteria A. Johnston (John Innes Institute, Norwich) demonstrated that the R plasmid R68.45 could promote chromosomal recombination in *Rhizobium* species and that stable recombinants could be formed in crosses between species. A single circular chromosome for *R. leguminosarum* was reported. In *Azotobacter vinelandii* many *nif* mutants have been characterised biochemically, but genetic analysis has been lacking. W. Brill (University of Wisconsin, Madison) reported that *nif* genes in these species could be transferred by transformation, but in contrast to *K. pneumoniae* they were not closely linked. More suprising was the fact that *nif*$^+$ transformants were obtained with DNA obtained from *Rhizobium*.

There have been several reports that plant lectins may determine the specificity of interactions between *Rhizobium* and legumes. D. Bauer (C. Kettering, Yellow Springs) showed that not all strains of *R. japonicum* bind the lectins of its host, the soybean. Those that did not could however, be induced to do so by whole soybean roots. This observation may resolve some of the discrepancies in the literature in which binding of lectins to some infective strains of *Rhizobium* has not been observed.

The symbiosis between *Azolla* and *Anabaena* has been used as a source of fixed nitrogen in Asian rice paddies for centuries. B. Rains (University of California, Davis) demonstrated that an equivalent of 90 kg ha^{-1} yr^{-1} may be contributed by this symbiosis. It is not possible however to cultivate the blue-green alga outside the plant so the goal of breeding for increased levels of fixation remains a distant one.

The role of *Spirillum* as a significant contributor of fixed nitrogen remains enigmatic. Although it was shown by J. Dobereiner (Embrapa, Brazil) to get into maize roots, it appears to contribute little to the nitrogen input of this plant though it may do so with some tropical grasses and wheat varieties.

The supply of energy to nitrogen-fixing systems was considered by several speakers to be a major limitation to increasing levels of fixation. R. Valentine (University of California, Davis) estimated that in the 'artificial nodule' in which NH$_4^+$-excreting strains of *K. pneumoniae* were grown, about 20 molecules of ATP are required for every molecule of nitrogen fixed, although this ratio varied depending on environmental factors. Invariably H$_2$ is liberated during the reduction of N$_2$, but some of this energy loss may be recouped if a hydrogenase is present. H. Evans (Oregon State University, Corvallis) discussed the importance of this reaction in root nodules and pointed out that a particularly effective strain of *R. japonicum* has hydrogenase activity.

If *nif* genes are to be introduced into new hosts suitable vectors must first be obtained. Evidence that DNA from the crown-gall bacterium *Agrobacterium tumefaciens* does in fact integrate into plant DNA was given by E. Nester (University of Washington, Seattle). DNA isolated from crown-gall tissue specifically hybridised with one particular fragment derived from *SmaI* digestion of the large tumour-inducing (Ti) plasmid of *A. tumefaciens*. This integrated plasmid is present in about 20 copies per plant cell and is transcribed in crown gall tissue, since RNA from this source hybridises specifically with it. These results were complemented by those of D. Schell (University of Ghent), who found that in some cases Ti plasmids contain large hairpin loops characteristic of some translocating sequences. In a strain which had lost both the ability to degrade octopene and to induce tumours one of the loops (length 40 μm) was missing.

The use of plant viruses as possible vectors was discussed by R. Meagher (University of Georgia, Athens). He showed that when the DNA of cauliflower mosaic virus was cloned in *E. coli* extra proteins were synthesised, but that none corresponded to normal virus proteins, which confirms the difficulties of obtaining accurate transcription and translation of eukaryote DNA in prokaryotes.

However, it was emphasised at the meeting that the most promising strategy for improving the economic contribution of biological nitrogen fixation to agriculture probably lies in the development of better types of already existing nitrogen fixation systems.

The conference also considered some of the legal, ethical and environmental implications of the scientific contributions. These discussions were strongly influenced by the present concern in the United States about the potential hazards of recombinant DNA research. This meant that while there was a general consensus of opinion that production of more efficient nitrogen-fixing plants and bacteria was desirable, a number of people were concerned about the possible environmental impact of such organisms even if they were formed by classical methods of gene transfer. ☐

Positronium spin conversion

from P. W. Atkins

A TECHNIQUE which can detect minute concentrations of triplet states of molecules in gases at normal pressures may have important applications in detecting small concentrations of some air pollutants. The technique depends on positronium spin conversion, a new development of the well-known interconversion of *ortho* and *para* hydrogen.

The interconversion of *ortho* and *para* hydrogen by paramagnetic species has been known, studied and understood for some time. The effect depends on the two nuclei responding to the magnetic field of the paramagnetic molecule; in a collision one of the protons is closer to the unpaired spin than the other, and so its magnetic moment, and therefore its spin orientation, is changed by a greater amount. This relative reorientation of the two proton spins switches an *ortho* molecule (where the two nuclear spins are parallel) into a *para* molecule (where the nuclear spins are in opposition). The rate of interconversion is not fast because it depends on the interaction of the field of the paramagnetic species with the two nuclear magnetic moments, and these are very small. If the magnetic moments were of the size typical of electron magnetic moments (about 2,000 times larger than nuclear moments), or if the *ortho* and *para* molecules could combine in some way with the radical and by so doing change their spin angular momentum by sharing it with the paramagnetic species, the rate of *ortho–para* conversion would be very much greater.

In a recent letter W. Brandt and D. Spektor (*Phys. Rev. Lett.* **38**, 595; 1977) have, in fact, taken the step which leads to a rapid interconversion rate. They have done this by replacing the hydrogen molecules, with their weak nuclear moments, by positronium, and studying the rate of interconversion of *para* positronium (e$^-$ and e$^+$ spins in opposition) and *ortho* positronium (e$^-$ and e$^+$ spins parallel). The magnetic moments of e$^-$ and e$^+$ are both of the order of a Bohr magneton, and so the (e$^-$, e$^+$) species can act as a sensitive probe for the existence of paramagnetic species in the gas phase (as well as in solids, as had been found previously). Alternatively, the positronium can attach to a paramagnetic species, and by a redistribution of spin angular momentum, switch from *ortho* and *para* while the species switches from triplet to singlet. In these ways positronium interconversion can detect free radicals and, as the authors show, respond to the presence of photo-excited triplet molecules in the gas phase.

The experiment is basically the observation of the quenching of scintillations from positronium in the presence of the impurity of interest (SO_2 or benzaldehyde for example). The positron source was a $5\,\mu$Ci ^{22}Na sample at one end of a 25-cm cylinder of diameter 10 cm, with an ultraviolet source at the other. Two detectors monitored the scintillations; one was placed behind the ^{22}Na source, and the other next to the chamber wall. The standard coincidence counting techniques were used to monitor the delayed coincidences between the 1.28 MeV γ ray from the source (which accompanies positron emission) and one of the 0.511 MeV γ rays from the annihilation of a positron by an electron. The experiment is repeated with and without ultraviolet illumination and coincidences for times greater than about 30 ns were stored. This choice of time delay eliminates positron annihilation from all states other than *ortho* positronium.

The role of the paramagnetic species (such as a photo-excited triplet state of benzaldehyde) is to convert the long-lived *ortho* positronium into *para* positronium, which annihilates rapidly. The authors examined argon, nitrogen, and air at atmospheric pressure with trace impurities, and found that the cross sections for quenching are very large, of the order of 1.5×10^{-12} cm^2 for benzaldehyde and 0.9×10^{-12} cm^2 for SO_2. These values are of the order of $10^4\,\pi a_0^2$, where a_0 is the Bohr radius, and indicate interaction ranges of the order of 50 Å. They appear to increase as $\sqrt{T}$ in the range 300–400 K.

The importance of the effect is its sensitivity, on account of its large cross section, to very small concentrations of photomagnetic trace impurities in air; triplet concentrations as low as 10^{-8} can be detected at atmospheric pressures. The authors speculate that their work will have implications for research on gas pollution, in particular on H_2SO_4 formation by the photochemical oxidation of SO_2 to SO_3 in the atmosphere. □

Molecular human cytogenetics

from Susumu Ohno

> One of the 6th series of annual ICN–UCLA symposia, entitled Molecular Human Cytogenetics, organised by R. S. Sparks and D. Comings, was held at Keystone, Colorado on 6–11 March, 1977.

THE meeting appropriately began with excellent reviews by D. E. Olins (Oak Ridge National Laboratory) on nucleosomes and by E. H. Davidson (CalTech) on DNA sequence organisation. A progress report by Davidson indicated that some of the short interspersed repetitious sequences, each a few hundred nucleotide pairs long, may actually represent the promoter or operator site for an adjacent unique DNA sequence. If RNA polymerase II can be modified by a cell type specific modifier subunit, the polymerase, so modified, can selectively transcribe a specific group of structural genes capped by the similar promoter sites. Thus, this particular class of repetitious sequences is at last gaining functional respectability.

Regardless of whether the functional subunit of nucleosomes is a histone dimer rather than a tetramer (R. Chalkey, University of Iowa), a nucleosome itself unquestionably consists of two histone tetramers that assure the equimolar representation by H2A, H2B, H3 and H4. 160 DNA base pairs may make one or two loops around a nucleosome. The distance between adjacent nucleosomes, however, may be variable. As a rule, it was thought to be represented by 60 exposed base pairs (Olins), but V. Allfrey (Rockefeller University, New York) remarked that in the rat liver, there are 170 exposed DNA base pairs between nucleosomes. In view of a proposed flip flop mechanism involving histone tetramers of neighbouring nucleosomes, this uncertainty about internucleosome distance is annoying to say the least. What was in everybody's mind was the fate of nucleosomes during active transcription and replication of DNA.

With characteristically beautiful photomicrographs, S. L. McKnight (Columbia University, New York), from Oscar Miller's laboratory, seems to have shown that a stretch of DNA, being actively transcribed as evidenced by the presence of RNA polymerase molecules and growing transcripts, seems to be associated with as many nucleosomes as that representing an adjacent spacer sequence. Allfrey, however, was of the opinion that an actively transcribing ribosomal RNA gene of the slime mould, *Physarum polycephalum*, is either not associated with nucleosomes or those nucleosomes that maintain the association are highly modified, by acetylation of histones perhaps. The latter possibility was, of course, not ruled out by McKnight. With a rather indirect but clever method applied to HeLa cells, R. L. Seale (University of Colorada Medical Center, Denver) presented good evidence that, during DNA replication, one-half of a replication fork (therefore two-quarters of a replication loop) still maintains nucleosomes. The apparent omnipresence of nucleosomes forces us to modify much of our thinking as was evident in J. Cleaver's (University of California School of Medicine, San Francisco) discussion of DNA repair enzymes.

From a string of beads, visible under the electron microscope, to a chromosome as seen under the light microscope, needs a great leap of the imagination. H1, which has a hydrophobic globular core and the very basic amino, as well as carboxyl, terminus is a good candidate for maintaining higher order helical packing of the string of beads by bridging nucleosomes at a certain interval. According to D. Cole (University of California, Berkeley) H5 (found in vertebrates with nucleated erythrocytes) as well as some of the so-called HMG proteins of I. Isenberg, can be considered as allies of H1. Furthermore, he has shown that each mammalian species generates not one, but several organ-specific species of H1. Data from sea urchin indicates that the basic histone genetic unit contains one each of the H1, H2A, H2B, H3 and H4 genes. Cole's findings and the similar finding by Isenberg (Oregon State University) for H2A indicates that the genome of higher vertebrates contains not one but several genetic units for histones that are the same with regard to the H4 gene but different with regard to H1 genes and to a lesser extent H2A genes. In this connection, an apparent paradox is noted with great interest. Using H4 message purified from HeLa cells, W. Prensky (Tufts University, Boston) reported that the number of histone gene copies in the human genome is only of the order of tens rather than hundreds and is localised on the short arm of chromosome 7 near its centromere. By contrast not only with sea urchins and frogs but also with the cat, the human genome apparently contains fewer copies of each of the multigene families. This is true for the 5S RNA genes (found on the long arm of chromosome 1) and also of the 18S and 28S RNA genes (distributed among five pairs of acrocentrics—chromosomes 15, 16, 17, 21 and 22).

I wonder if humans owe their extraordinary longevity to the fact that they possess so few copies of these genes. It seems to me that having too many copies of a functionally ubiquitous gene is a curse rather than a blessing to somatic cells. Mutations which alter function (suppressor-type mutations of RNA genes, for example) sustained by a few copies out of hundreds or thousands are not likely to be particularly deleterious, and so may accumulate, resulting in more and more mistranslations and mistranscriptions leading finally to the general deterioration so characteristic of the ageing process. With fewer gene copies, mutated cells will be eliminated more efficiency thus delaying ageing.

Of winged beans and Wom Poms

from Robert M. May

ADMIRERS of Michael Flanders and Donald Swann will recall their hymn to the fabulous Wom Pom plant (Angel Record 35797): "You can do such a lot with a Wom Pom / You can use every part of it too . . . The flesh in the heart of a Wom Pom / Has the flavour of porterhouse steak / And the juice is a liquor / That will get you higher quicker . . . *Gaudeamus* Wom Pom, gladly we salute / *Vade mecum* Wom Pom, philanthropic fruit."

Nature's closest approximation to the Wom Pom may well be the little-known tropical legume, *Psophocarpus tetragonolobus* or winged bean. In its study of underexploited tropical plants with promising economic value (see *Nature* **265**, 209; 1977), a panel of the US National Academy of Sciences under the direction of Noel Vietmeyer decided that the exceptional merits of the winged bean deserved a separate and deeper examination. The fruits of that work are set out in *The Winged Bean: A High-Protein Crop for the Tropics* (NAS, Washington DC, 1975).

Today the winged bean is grown only as a backyard crop in Papua New Guinea and Southeast Asia. These regions are, however, typical of the humid tropical zone that includes large parts of Central and South America, the Caribbean, Africa, Oceania, and West Asia, where protein deficiency is high and the plant is still unknown; not many edible crops with such high protein content will grow in these regions. Unlike the soybean (where only the seeds are used), all parts of the winged bean can be eaten: tubers, seeds, leaves, flowers, and shoots.

The immature pods are highly palatable, and can be eaten raw. The seeds are similar in composition to soybeans, averaging 34% protein (by dry weight) and 17% oil. The seeds give an edible oil, with a good proportion of polyunsaturated essential fatty acids. The tuberous roots are slightly sweet, and contain 20% protein (by dry weight). This is spectacularly higher than the protein content in other edible roots and tubers such as cassava (1%), potatoes (2%), sweet potatoes (2%), or yams (2%).

Like other leguminous plants, the winged bean fixes atmospheric nitrogen by bacteria in nodules on the roots. Compared with other edible legumes, *P. tetragonolobus* appears to have more and larger nodules on its extensive root system, which may account for the plant's exceptional protein content. These factors are also probably responsible for the plant's ability to grow well in tropical soils poor in nitrogen, and in newly cleared soils (without the inoculation with appropriate soil bacteria demanded by many other tropical legumes). It can also be used in crop rotations to restore soil nitrogen.

Little is known about the varieties of *P. tetragonolobus*. Those currently cultivated require staking to produce high yields of pods and seeds. The NAS report acknowledges that this method of agriculture is impractical and uneconomical for mass cropping, and that not all winged bean pods mature at the same time, so that the plant is not likely to rival the soybean as a large-scale commercial product in the near future. "Its potential is as a subsistance crop or as a cash crop for small markets. For these purposes, the fact that it produces food during many months is an advantage, and staking is not a serious handicap".

One of the long term benefits that may well come from research on *in vitro* recombinant DNA is better crops, genetically engineered to our requirements. In the short run, however, we could make better use of what nature has provided, particularly in the tropics.

How a chromosome or rather a chromatid manages to pack 10^8 or more DNA base pairs into itself is a mystery still unresolved. After listening to discussions of sister chromatid exchanges by S. Latt (Children's Hospital Medical Center, Boston) and S. Wolff (University of California Medical Center) and of meiotic segregation by M. Moses (Duke University School of Medicine), one cannot help but marvel at the ease with which two sister DNA strands manage to sort themselves out without too much unwinding. All the tortuous models proposed so far are likely to be well off target. To discuss the mechanism of Q and G-banding and of R-banding without knowing the packing method the chromosome uses is likely to be futile. Although D. Comings (City of Hope Medical Center) pointed out that a 5% difference in GC/AT ratio may make a 50% difference in fluorescence intensity, the fact that anti-single base antibodies (O. J. Miller) as well as G–C specific antibodies (J. H. Van de Sande), can also band chromosomes, seems to indicate that what matters is not the base composition of a whole long stretch but short stretches here and there that occupy exposed or accessible positions on the chromosome. I have amused myself with the thought that a solitary human chromosome left in man–mouse somatic hybrids still exhibits its own characteristic banding pattern, although its chromosomal proteins by then are likely to be entirely of mouse origin.

Because of strenuous afternoon exercise on skis and skates and social evenings not many people attended the last session, on evolution, which I thought the best. Of man's relation to the great apes, both A. Wilson (University of California, Berkeley) and P. Pearson (University of Leiden) pointed out that the genetic distance between the chimpanzee and the gorilla is considerably greater than that between man and the chimpanzee. The tendency of certain autosomes to be extremely conserved was noted both in primates (Pearson) and Equidae (O. A. Ryder). Even rhesus monkeys seem to maintain a homologue of human chromosome 1. Whether such an apparent chromosomal conservation correlates well with the conservation of its individual genes, as is the case with the mammalian X, is an evolutionary question of utmost interest. As no functional significance can be assigned to highly repetitious DNA base sequences (so-called satellite DNA), their evolutionary role cannot be conjectured. Nevertheless, they have a peculiar habit of jumping around, ignoring the pair-by-pair homology of diploid organisms, the human Y-specific repetitious sequences being an exception (L. M. Kunkel, Johns Hopkins Hospital). Human satellite DNAs 1 to 4, some of them more ancient in origin than others, have apparently been jumping around as free spirits during the course of evolution that first branched out gibbons and then the anthropoid apes and man (J. R. Gosden, Western General Hospital, Edinburgh). E. Southern pointed out some years ago that the evolutionary fate of highly repetitious sequences is to become moderately repetitious by accumulation of random mutational base changes. Unless a mechanism exists for eliminating old repetitious sequences, the genome size should continue to increase with every new addition of highly repetitious sequences. While most species have apparently invented this elimination mechanism, the kangaroo rats (*Dipodomys*) of North American deserts have not. Among this group of leaping rodents larger genome sizes are correlated with a greater amount of highly repetitious DNA (F. T. Hatch, Lawrence Livermore Laboratory).

Sex chromosomes continue to unravel their mysteries ahead of autosomes, the *in vitro* study of the X-inactivation mechanism now seems possible. Using three X-linked marker enzymes, G. Martin (National Institutes of Health) reported that mouse ovarian teratoma cells, kept in an undifferentiated state with the help of the feeder layer, express the genetic activities of both X chromosomes. As soon as they are allowed to organise and differentiate one X-chromosome is inactivated. Rapidly accumulating evidence mainly due to S. S. Wachtel has all but verified the proposed testis-organising function of the H-Y antigen (S. Ohno, City of Hope Medical Center). But the actual location of this testis-determining H-Y gene is now problematical. Although the presumptive existence of this gene in multiple copies could still salvage its Y linkage, X linkage of the H-Y gene in the normally inducible state with the Y carrying its activator gene, is becoming increasingly attractive. ☐

Objective authentication

from C. R. Cavonius

Authenticity in Art was the subject of an interdisciplinary symposium at the Van Gogh Museum, Amsterdam, on 12 March 1977. The symposium, which reflected the increasing interest in the use of objective techniques in authentication, was organised by H. L. C. Jaffé (Art Historical Institute, University of Amsterdam) and L. H. van der Tweel (Van Danzig Foundation).

THE discussion clearly showed the complementarity of techniques derived from physical and physiological science, and from modern graphical analysis. S. J. Fleming (Oxford University) described changes in the pigments used by artists over the centuries. The obvious possibility of rejecting a later forgery because it contains pigments that were not available to the original artist has been extended by methods that in some cases enable the dating of different samples of the same pigment on the basis of their radioisotope ratios or trace contaminants. This has proven especially useful in the case of the ubiquitous pigment lead white which, depending on the era in which it was manufactured, contains varying amounts of impurities, or different crystalline structures (although the chemical composition remains the same). Fleming concluded that if museums and collectors regularly used physical dating techniques, the chance of success by forgers would become vanishingly small.

Physical methods are, however, of little help in discriminating between artists of the same school, who tended to use similar materials. This problem was discussed by J. Bruyn (Art Historical Institute, Amsterdam) within the framework of the current exhibition in Utrecht of works by Jan van Scorel. Recent developments in infrared scanning methods make it possible to reveal the artist's sketches under all pigments other than black, and this technique has revealed several cases in which different parts of a painting were sketched by different artists. Bruyn further explained how an analysis of underpainting can aid in authenticating a painting, since members of a given school tend to follow the master's technique, whereas copyists attempt only to reproduce the appearance of the surface.

Prints and drawings present a special problem, since they offer little material for physical analysis. In this case, A. Perrig (University of Hamburg) demonstrated how an analysis of the fine structure of an artist's line can aid in identifying a drawing in cases in which the overall style is ambiguous. As an example, Perrig showed that the cross-hatching in several putative Michelangelos was done with a stroke that does not appear in any of his authenticated works, and through a series of steps that resembled a good detective mystery, traced their origin to Cellini.

Two different methods for describing an artist's style in objective terms were proposed by J. J. Denier van der Gon (University of Utrecht) and J. Storm van Leeuwen (Royal Library, The Hague). The first reported the results of recent experiments in which the velocity and position of an artist's hand were recorded while she sketched several types of line. When drawing repetitive lines for shading, velocity increased in proportion to line length, whereas when copying a line, or drawing an outline, velocity remained essentially constant, suggesting that the two types of activity are mediated by different neuromuscular control systems. If it were possible to deduce from a drawing which types of motion had been used for specific lines, it might be possible to identify copies, since these would presumably consist predominantly of constant-velocity lines. However, Denier van der Gon admitted that this would be technically difficult.

Storm van Leeuwen described his experience with a method that is already available for describing an artist's style in objective terms: the pictological method devised by van Danzig, which he used to conclude that only 33 of 116 paintings that were attributed to Frans Hals in the 1930s were actually from his hand; subsequent authentication through, for example, pigment analysis has in general confirmed van Danzig's analysis. The heart of this method is the identification of at least 100 characteristics in well-authenticated works of a given artist. If a dubious painting contained 75% of these, van Danzig concluded that it was authentic. Storm van Leeuwen reported a high rate of success in applying pictological analysis to objects as diverse as bookbindings, but cautioned that the method is difficult to learn.

In the general discussion the view that connoisseurship must remain the ultimate test of a work of art was put forward. But this traditional view had clearly received a strong challenge from the more objective methods presented. □

Continental drift changes climate

from Peter J. Smith

THE annual mean temperature difference between the equator and the north pole is at present about 41 °C (equatorial 27 °C to polar −14 °C). But evidence from the fossil record makes it clear that temperatures during the Mesozoic, for example, were generally higher than they are now and that the large equator–north pole temperature drop currently observed is probably atypical of the past few hundred million years of geological time. So why has the temperature gradient increased? Why is late Caenozoic climate abnormal? One possibility is that since at least the Palaeozoic the Earth has been influenced by extraterrestrial effects such as variations in solar luminosity, as suggested by Ulrich (*Science* **190**, 619; 1975). However, Donn and Shaw (*Geol. Soc. Amer. Bull.* **88**, 390; 1977) now claim that the appeal to external processes is unnecessary and that climatic changes in the northern hemisphere during the Mesozoic–Caenozoic may be attributed entirely to changing terrestrial geography.

Their evidence comes from the application of a modified form of the thermodynamic meteorological model of Adem (*Tellus* **14**, 102; 1962 and subsequent papers), the purpose of which is to estimate the temperature of the Earth's surface and atmosphere from the radiation balance. The details are complex and can barely be summarised. Suffice it to say that the model involves such factors as the solar radiation received at the Earth's surface, the surface albedo (reflectivity), latent heat loss from the surface by evaporation, heat of condensation in the atmosphere, cloudiness, heat storage in the oceans and atmosphere, the horizontal eddy diffusion of heat, and heat added to the atmosphere by short-wave and long-wave radiation. What emerges from a consideration of these thermal effects is an equilibrium temperature distribution; and the model can certainly be said to work insofar as it has been used successfully to describe the present climate.

The crucial element as far as Donn and Shaw are concerned, however, is the change in the Earth's albedo with time. The present albedo of the Earth as a whole is about 30%; that is, about 30% of the incident solar radiation is reflected back into space and is thus unavailable for warming the Earth's surface and atmosphere. But this average conceals large variations, for whereas the albedo of clouds is about 90%, that of ice and snow is 60–80% and that of certain land and water areas is less than 10%. Moreover, because of its transparency and mobility, water transports heat to a greater depth than does land and is thus more capable of storing heat. The amount of heat absorbed by the Earth's surface, and thus available for later warming of the atmosphere, is therefore dependent upon the relative proportions and positions of the different types of surface cover.

And the proportions and arrangement of continents and oceans in the northern hemisphere have changed considerably over the past 200 Myr because of continental drift and possibly polar wandering. The albedo and heat storage characteristics must likewise have changed. To see if such changes are sufficient to account for the observed climatic changes, Donn and Shaw have therefore used their modified Adem model to determine the surface temperature distribution for the early Triassic (200 Myr ago), the mid-Jurassic (150), the Palaeocene (65), the Oligocene (35) and the present. The point of beginning with the early Triassic is that this epoch preceded the separation of Europe, America and Africa and marked a time when much of the northern hemisphere was water. (Of course, much of the northern hemisphere was also under water during the Cretaceous, when large continental areas were submerged. This period has not been considered in order to avoid having to distinguish between the thermal effects of land and large epeiric seas.)

What the analysis shows is that during the early Triassic the temperature difference between equator and pole over most of the northern hemisphere was only about 20 °C. But as more and more land moved in from the southern hemisphere and drifted towards the north pole over the succeeding 200 Myr, the equator–pole temperature drop rose to about 40 °C, which agrees well with the currently observed value of 41 °C. Throughout this period, however, the tropics remained at 25–30 °C. In other words, the increasing temperature gradient was brought about by a gradual decrease in polar temperature unaccompanied by any significant change in equatorial temperature.

The increasing gradient tied to a nearly constant equatorial temperature inevitably led to a decrease in the overall mean northern hemisphere temperature—in fact, a more or less uniform fall of about 3 °C throughout the 200 Myr. But temperature reductions in the higher latitudes were not only greater but also less uniform. In the 60–70°N band, for example, the annual mean temperature fell by about 5 °C during the first 165 Myr and by about the same over the remaining 35 Myr. During the same intervals the proportion of land in that latitude band rose 0–50% and 50–100% respectively, emphasising again the importance of 'continentality' in producing temperature decline. Incidentally, the model analysis shows that the mean 60–70°N temperature fell below freezing point 10–15 Myr ago, which is in good agreement with the onset of North American glaciation.

In summary, then, it would seem that continental drift is capable of explaining fully the gross changes in northern hemisphere temperature for the past 200 Myr. Whether the same can be said for the southern hemisphere, where the present equator–pole temperature drop is even higher at 77 °C, remains to be seen. Donn and Shaw promise that analysis later. □

100 year ago

BERLIN dealers in delicacies have recently received from the south, and especially from Upper Italy, immense quantities of edible birds which have been captured there in their flight northwards. Unfortunately there were not only snipe, fieldfare, and larks, or so-called "delicacies" among the birds sent, but also singing birds, that are never eaten in Germany, such as goldfinch, thrush, and nightingales. The animals were caught on their migratory flight by means of nets, or surprised during the night and indiscriminately killed. A new indication of the importance of an international law for bird protection!

Extended radio galaxies

W. A. Christiansen

National Radio Astronomy Observatory, Charlottesville, Virginia and University of North Carolina, Chapel Hill, North Carolina 27514

A. G. Pacholczyk

National Radio Astronomy Observatory, Charlottesville, Virginia and Steward Observatory, University of Arizona, Tucson, Arizona 85721

John S. Scott

University of Maryland, College Park and Kitt Peak National Observatory, Tucson, Arizona.

Observations of extended radio sources are interpreted in terms of a picture for radio source evolution involving multiple ejections of ram pressure confined plasmons in which instabilities lead to the formation of turbulent hot spots and to in situ *particle acceleration. The hypothesis of ram pressure confined turbulent plasmons leads to a coherent theory of various radio phenomena including compact radio sources, radio tail galaxies and extended double radio sources.*

ALTHOUGH the powerful extended double radio sources were among the first extragalactic radio sources to be extensively studied, a detailed understanding of their nature is still elusive. The ultimate source of the energy liberated in these sources remains a problem, and will not be dealt with here. We present a coherent picture of the observed structural, spectral and polarisation features of the extended double sources, assuming that an adequate amount of energy is released and properly directed in the central region of the parent object.

A natural model for double radio sources assumes the components of a given source to be ram pressure confined plasmons ejected from a galaxy into an external medium. More exotic models have been developed to explain the following difficulties: (1) Rayleigh–Taylor instabilities, induced in the plasmon because of deceleration, may cause disruption of the plasmon[1]. (2) Large adiabatic energy losses are expected because of the expansion of the decelerating plasmon. (3) Recent observations indicate the presence of highly polarised 'hot spots' in some extended sources[2–4]. If hot spots are confined by ram pressure, high densities of thermal matter ($n \sim 10^{-2}$ cm^{-3}) are required to achieve penetration to the observed distance. Polarisation observations, however, indicate that this thermal density is about an order of magnitude smaller ($n \sim 10^{-3}$ cm^{-3}) (refs 2, 3). (4) The relatively high equipartition magnetic field intensity in the hot spots implies synchrotron lifetimes on the order of 10^4 yr (refs 2, 3). This is only of the same order as the light travel time from the central source to the observed distance of the hot spot.

We argue that ram pressure confined plasmons do develop instabilities; however, the spectra and amplitude of the instabilities are severely limited by the bow shock flow. These limited instabilities lead to the formation of hot spots, the development of turbulence and *in situ* particle acceleration, so that the above listed arguments are inapplicable.

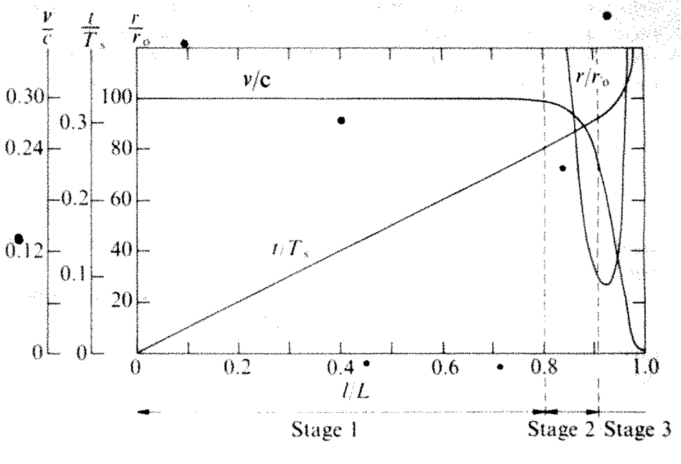
Observations of radio tail objects (and bent double structures) which we assume to be phenomenologically similar to the more energetic doubles discussed here, clearly indicate a number of discrete ejection events (that is, multiple explosions). We therefore adopt a multiple ejection picture (compare ref. 6); this hypothesis (unlike the single ejection) leads to initial nuclear phase luminosities consistent with observations of QSOs.

Plasmons evolution

The evolution of plasmons in a multiple explosion picture for radio galaxies may be separated into four stages (Fig 1).

Stage 1: the plasmon created in the most recent explosion adiabatically expands along the channel formed by the previous explosion[6], resulting in a low surface brightness. Stage 2: this plasmon, on encountering the debris from previous explosions, is rapidly decelerated, adiabatically compressed and greatly brightened. Stage 3: Rayleigh–Taylor instabilities develop near the front of the plasmon, and generate turbulence throughout the plasmon, leading to the acceleration of particles by the betatron and second order Fermi mechanisms[7,8]. Stage 4: deceleration drops to zero and the plasmon expands.

Fig. 1 Velocity of the front of the plasmon in units of light velocity (V), travel time in units of stopping time t/T_S, and a scale height r/r_0 ($r_0 = 1$ kpc) of a plasmon in a channel as functions of the position of the front of the plasmon relative to the length of the Channel l/L. Channel length: diameter is 10. The mass of the plasmon is 0.1 of the total mass of the debris at the end of the tunnel from previous events.



The instabilities no longer grow and the turbulence (and consequent particle acceleration) decays.

Instabilities and hot spots

Linearised calculations indicate that ram pressure confined plasmons are Rayleigh–Taylor and Kelvin–Helmholtz unstable. It seems that the instabilities grow rapidly enough to disrupt the plasmons[1].

Near the front of the plasmon the Rayleigh–Taylor instability is dominant with a growth time $\tau \sim (\lambda/|A|)^{1/2}$, where λ is the instability wavelength and $|A|$ is the absolute value of the plasmon acceleration. For ram pressure confined plasmons $|A| \sim \rho_B v^2/\rho r$, where ρ_B is the background gas density and v, ρ and r are the centre of mass velocity, average density and scale height of the plasmon, respectively. Therefore

$$\tau \sim (\rho/\rho_B)^{1/2} (\lambda r)^{1/2} v^{-1} \qquad (1)$$

As $|A|$ is largest at the beginning of Stage 3 (Fig. 1) the growth rate of all instabilities should be most rapid at this time, and the existence of hot spots and bright ridges, which we associate with growing instabilities, should be most prominently associated with this stage.

Previous calculations did not specifically take into account the interaction between growing surface instabilities and the two-dimensional hypersonic flow of shocked ambient gas around the ram pressure confined plasmon. This flow does not stabilise the surface in the sense that it prevents the growth of instabilities but it does strongly limit the amplitude of the instabilities by sweeping them around the nose of the plasmon into its wake. Therefore, these instabilities contribute to turbulence but are swept away before they reach amplitudes large enough to disrupt the plasmon.

At the stagnation point, the flow velocity of the shocked gas is zero. Above the stagnation point, however, the shocked gas flow has a non-negligible component normal to the surface[10]. Instabilities growing near the stagnation point encounter this flow as soon as they protrude above the surface and are efficiently suppressed.

Away from the stagnation point, the flow is nearly tangential to the surface. The tangential acceleration, A_T, of an instability due to the ram pressure of this flow is thus

$$A_T = (k\rho_{sh}v^2_{sh})/\rho\lambda \qquad (2)$$

where k is a dimensionless constant of order unity, ρ_{sh} and v_{sh} are the density and tangential velocity of the shocked gas, respectively. Numerical calculations[10] indicate that

$$\rho_{sh}v_{sh} \sim \rho_B v$$

$$\text{and} \qquad v_{sh}/v \sim \sin\alpha + 2.2(h/r)\cos^3\alpha \; (h<0.1r) \qquad (3)$$

where α is the angle between the plasmon's velocity and the surface normal, and h is the normal distance above the surface. Instabilities continue to grow until the velocity of the instability relative to the plasmon exceeds the signal speed in the plasmon, v_s. The instability then loses communication with the rest of the plasmon, is decoupled, and ceases its growth. For ram confined plasmons, $v_s \sim v\,(\rho_B/\rho)^{1/2}$, and the time required for decoupling an instability is

$$t_{dc} \sim v_s/A_T = (\rho_B/\rho)^{1/2} v A_T^{-1} \qquad (4)$$

Well away from the stagnation point ($\cos^3\alpha \ll \sin\alpha \sim 1$), $A_T \sim \rho_B v^2/\rho\lambda$. Therefore, $t_{dc} \sim (\lambda^2\rho/v^2\rho_B)^{1/2}$, and one may conclude that $t_{dc} < \tau$ for any $\lambda < r$. This means that Rayleigh–Taylor instabilities do not develop far from the front of a plasmon, and is consistent with observations which seem to indicate that bright hot spots (which we identify with large amplitude instabilities) are always found near the leading edges of extended sources.

Near the front of the plasmon ($\cos^3\alpha > \sin\alpha \sim 0$), the tangential acceleration of an instability depends on the value of h (which is equal to its amplitude). During the linear phase of instability growth

$$t_{dc} \sim (\rho/\rho_B)^{1/2} (\lambda r/hv) \qquad (5)$$

where h is the average amplitude of an instability in the interval before it is decoupled. Comparing this result with the growth time (equation (1)) we conclude that instabilities near the front of the plasmon for which $(\lambda r)^{1/2} < h$ would not develop large enhancements in their amplitudes before being swept away. A natural upper limit on h is the thickness of the shocked region, $h < 0.1r$. Therefore, although the initial spectrum of instabilities is unknown, it is clear that any instability for which $(\lambda r)^{1/2} < 0.1r$ will not develop a large increase in its amplitude.

In conclusion, only a limited spectrum of Rayleigh–Taylor instabilities having wavelengths in the range

$$0.01r < \lambda < r \qquad (6)$$

are capable of developing, near the front of a plasmon, the large increases in amplitude which are necessary for the enhancement of magnetic field and brightness observed in hot spots. Indeed, the sizes of observed hot spots fall in this range[2–4]. Furthermore, there is no evidence for structure in extended radio sources at a scale smaller than the preceding lower limit[4].

Later in Stage 3, $\rho_B/\rho \to 1.0$ and $|A| \to 0$. As a result, the instabilities stop growing, expand and blend with the extended source.

Acceleration and spectra

Equipartition magnetic fields in double-lobed sources (especially in the hot spots) lead to unacceptably large synchrotron losses in times short compared with the lifetime of the radio component. In particular, the frequency, ν_T, at which synchrotron losses become dominant (the frequency where the spectrum should begin to exhibit exponential steepening) is predicted to be within or possibly below the radio window.

This is not the case, however, for our model, in which the position of ν_T in the source's spectrum does not move steadily to lower frequencies. Because of the compression, betatron and Fermi accelerations which occur at various stages of the plasmon's evolution, ν_T at times increases.

The general form of the function $\nu_T(t)$ is[11]

$$\nu_T = [(\text{const.})H(t)\exp(2a)]/[(\textstyle\int H^2(t)\exp(a)\mathrm{d}t)^2] \qquad (7)$$

where a is the time-dependent sum of the coefficients of particle energy change (for example, Fermi acceleration coefficient, adiabatic loss coefficient, etc.). (See Pacholczyk and Scott[7,8].)

During Stage 1, equation (7) implies that ν_T decreases, although synchrotron losses are minimal, since the plasmon is expanded to a large scale size and the magnetic field is small.

The compression during Stage 2 implies that ν_T increases as r decreases

$$\nu_T \simeq 8.2\times10^{23}\, H^{-3}(r_2)(\langle\dot{r}\rangle^2/r_2^2)(\ln r_2/r_1)^{-2}\ (\text{Hz}) \qquad (8)$$

where subscripts refer to the ends of respective stages. The development of turbulence during the early parts of Stage 3 leads to a further increase in the magnetic field through the turbulent dynamo effect, implying that although r increases during Stage 3, ν_T also increases (compare equation (7)). A given component will not be perfectly homogeneous since turbulence develops at different rates in different parts of the source. This means that the frequency of the exponential cutoff, ν_T, will be a function of position in the source, with the regions where the instabilities are most highly developed (that is, hot spots) having the largest value of ν_T.

The overall spectrum early in Stage 3 represents the composite of a series of different exponential cutoffs corresponding to different parts of the plasmon. This implies that the total spectrum will begin to curve (but not exponentially cutoff) at a value of ν_T corresponding to parts of the plasmon where turbulence has not significantly developed. This value of ν_T

is that at the end of Stage 2 (compare equation (8)), which is the point in the evolutionary sequence just before the onset of turbulence. For the observed scale size (6×10^{22} cm), equipartition magnetic field (6×10^{-5} G), and $\langle \dot{r} \rangle \simeq$: $0.1c$ appropriate to Cyg A, we predict that the spectrum should start to bend at

$$\nu_{\text{bend}} \simeq 10^{9}\ \text{Hz} \tag{9}$$

a value close to that observed in this source[6], although uncertainty in this value is relatively large.

As turbulence develops first at leading edges of plasmons, high resolution observations of sources in the early parts of Stage 3 should show less curvature (higher average ν_T) and flatter spectra at the front of the components than at the rear. There are some observational indications that this is so in Cyg A (ref. 2).

Sources well into Stage 3, with fully developed turbulence throughout the entire plasmon, will have lower overall polarisation (because of the turbulence), and ν_T will be shifted to higher frequencies through the source (see equations (7)–(9)) than younger, less polarised sources. In addition, because the plasmon is expanding during Stage 3 the integrated luminosity gradually decreases although acceleration is moving ν_T to higher frequencies so that for a given event the maximum luminosity is reached early in Stage 3.

Depolarisation and energetics

For Cyg A the diameter of the hot spots is ~ 3 kpc. The polarisation observations[2,12] imply a cellular structure with $N = 10$ cells along the line of sight through the hot spot[2] and a value of $nH \sim 5\times 10^{-7}$ G cm^{-3}, where n and H are the thermal particle density and magnetic field in the hot spot. Assuming, since the hot spot is compressed, $H = \eta H_{\text{EQ}}$ where H_{EQ} is the equipartition field for the entire plasmon, the value of the compression coefficient, η, can be determined by comparing the surface brightness of the hot spot with the total surface brightness of the plasmon

$$\eta^{\alpha+1} = \left(\frac{F_{\text{HS}}}{F_{\text{total}}}\right)\left(\frac{r_{\text{total}}}{r_{\text{HS}}}\right)^{2}$$

where $F_{\text{HS(total)}}$ and $r_{\text{HS(total)}}$ indicate the observed flux and radius of the hot spot (entire plasmon), respectively, assuming $F(\nu) \sim \nu^{-\alpha}$. For Cyg A, $\eta = 3.6$; therefore $n = 2.3\times 10^{-3}\text{cm}^{-3}$. The identification of hot spots as instabilities invalidates the application of the ram confinement condition to the hot spots[12] themselves. This condition (properly applied to the entire plasmon) is consistent with the density derived above. Given the velocity, $v \sim 0.1c$, and the density derived from polarisation arguments above, the total kinetic energy of the plasmon is $E_{\text{KE}} \sim 2\times 10^{61}$ erg. The ratio of the particle and field equipartition energy to the kinetic energy is then $E_{\text{EQ}}/E_{\text{KE}} = 1.3\times 10^{-2}$. Therefore about 1% of the bulk kinetic energy of the plasmon has been converted through instabilities and turbulence into relativistic particle and field energy. The value for this ratio is consistent with the value of 2% derived previously in the plasmon model for the head–tail radio sources[7].

Faraday rotation

The multiple explosion hypothesis predicts the existence of non-luminous relic plasmons outside the currently active radio-emitting sources. There is evidence that high-density relics may exist near Cyg A. Observations indicate that the south-following (Sf) component has a rotation measure of -1100 rad m^{-2} while the north preceding (Np) has a rotation measure of $+215$ rad m^{-1} (refs 2, 13). This large difference in the rotation measure between the two components can be interpreted as a result of the source being viewed along a line of sight which intersects one of the relic plasmons. If the source axis is not perpendicular to the line of sight (Fig. 2), radiation from the Sf component passes through a relic plasmon before reaching the observer while radiation from the Np component does not. The difference in the rotation measures would then be a measure of the magnetic field intensity (H_{relic}), thermal particle density (n_{relic},) and diameter (d_{relic}) of the relic plasmon, that is, $H_{\text{relic}} n_{\text{relic}} d_{\text{relic}} N^{-1/2} = 10^{15}\ \Delta RM$, where $\Delta RM = 1315$ rad^{-2}, and N is the number of magnetic cells along the line of sight through the relic.

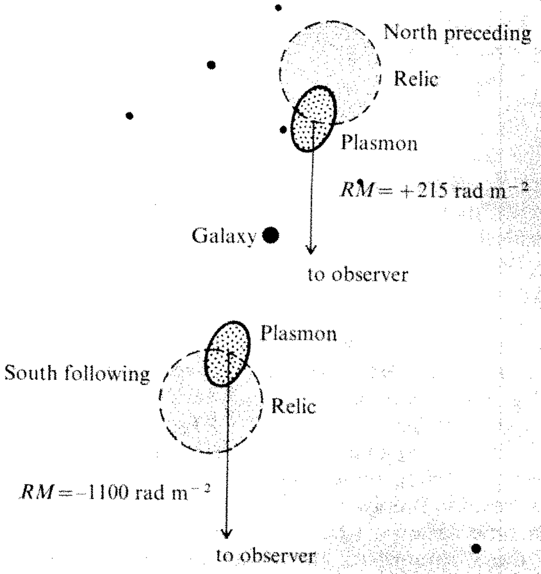


Fig. 2 Schematic representation of the radiating plasmons and relics in Cygnus A. The observed large rotation measure of the south-following component is understood in terms of the large path length of the radiation through the relic plasmon.

The largest differences in rotation measure should occur for sources with high-density relics when the most recent plasmons are in Stage 2 or early Stage 3 and the radio axis lies near the line of sight. Later in Stage 3 when coalescence of the most recent plasmons with relics is nearly complete the rotation measure differences will disappear.

Also, for Cyg A the Sf component must be closer to the observer (Fig. 2) Therefore, because of the difference in light travel time for the emission from the two components, the Sf component should be more advanced in its evolution. If, as was assumed earlier, Cyg A is located at the beginning of Stage 3 in its evolution, the fact that the Sf component is slightly older should imply: (1) Sf luminosity > Np luminosity; (2) Sf polarisation < Np polarisation; and (3) the hot spot in Sf should have a higher surface brightness. All three effects are observed.

X-ray emission

Several authors have pointed out that the X-ray emission from the bow shocks of ram pressure confined plasmons will be relatively small. For Cyg A the predicted bow shock X-ray luminosity would be $\sim 10^{42}$ erg s^{-1} (ref. 14). In addition, the inverse Compton X-ray emission from the interiors of active radio sources is not large[15]. The detection of an X-ray source associated with Cyg A with a luminosity of 2×10^{45} erg s^{-1}, was reported, however, and thermal bremsstrahlung from an extended region of high temperature gas ($T \gtrsim 10^{8}$ K) was suggested[14].

We attribute this X-ray emission to a thermally relaxed ($T \sim 5\times 10^{8}$ K) relic plasmon whose density and mass may then be estimated

$$n_{\text{relic}} 0.51\ d_{\text{relic}}{}^{-3/2}\ (\text{cm}^{-3})$$

$$M_{\text{relic}} \lesssim 1.15\times 10^{43}\ d_{\text{relic}}{}^{32}\ (\text{g}) \tag{10}$$

where d_{relic} is the diameter of the relic cloud in units of 10 kpc. Using density and rotation measure, we can estimate the relic magnetic field

$$H_{\text{relic}} \gtrsim 3\times 10^{-8}\ d_{\text{relic}}{}^{1/2}(\text{G})$$

Assuming $n = 2\times 10^{-3}$ (see preceding section) the mass of the currently active source in Cyg A is $M_{\text{act}} \sim 2\times 10^{42}$ g.

Although the observed X-ray source undoubtedly is partially composed of heated intergalactic gas, a reasonable estimate of its mass would be

$$M_{\rm relic} \sim M_{\rm act} N_{\rm inj} \qquad (11)$$

where $N_{\rm inj}$ is the number of plasmons accumulated in the relic over the lifetime of the source. An upper limit on the number of explosions is

$$N_{\rm inj} \lesssim 7\, d_{\rm relic}{}^{3/2} \qquad (12)$$

The observed X-ray luminosity can be maintained by the injection of an energy equivalent to the currently active source in Cyg A at a rate of ~ 1 (10^8 yr^{-1}). This implies $N_{\rm inj} \lesssim 100$, so $d_{\rm relic} \gtrsim 60$ kpc, $H_{\rm relic} \gtrsim 7 \times 10^{-8}$ G, and $M_{\rm relic} \lesssim 10^{11} M_\odot$.

It is interesting that with these relic parameters, the fastest process for filling the channel through which new plasmons must travel is simply back filling by the relic gas. This occurs on a time scale ~ (the channel length)/(relic sound speed). For these parameters, the filling time is $\sim 10^8$ yr, a value consistent with $N_{\rm inj} \approx 100$, and for which the channel will remain continuously open.

Morphology

The model of radio sources presented here emphasises (1) the multiple ejection of plasmons, and (2) the *in situ* acceleration which occurs when these plasmons are significantly decelerated by ram pressure. The predicted morphology resulting from these effects should be consistent with observations.

Sources with prominent hot spots should be associated with the early parts of Stage 3. Examples other than Cyg A are 3C 33, 3C 390.3 and 3C 61.1. (The latter source also shows a strong 'bridge' feature which can be ascribed to the reflection wave generated as the plasmon 'bounces' off the relic at the beginning of Stage 3).

Other possibilities include subsequent events which occur quickly enough so that the expanded relic is still visible when the latest plasmon encounters it. An example of such a source might be DA240.

If the channel is not straight (because anisotropic ram pressure occurs when there is a density gradient in the external medium[17,18]), some deceleration of the plasmons will occur soon after they leave the parent Galaxy, as the plasmons hit the curved wall of the channel. This causes brightening of the component close to the galaxy, resulting in such structures as bent doubles and wide-angle tails (for example, 3C465, 3C338, 1231+674, 1433+553) (ref. 19). Such structures are found in clusters of galaxies where density gradients are likely to be found.

If the velocity of ejection of the plasmons is comparable with the speed of motion of the Galaxy through the ram-confining medium, subsequent plasmons are not ejected into the channel of the previous plasmoid. Each ejected plasmon is then decelerated by the external medium, and the resulting structure is a radio tail.

In both bent doubles and tails the deceleration process is more gradual than it would be in the case where the plasmoids encounter a massive relic. This implies that the brightness for these two cases should be smaller than for straight doubles. This effect seems to be borne out by observations[19].

Because of the density gradients likely to be present, and the acceleration of the parent Galaxy, we expect straight channels to be rare in clusters of galaxies, and bright straight doubles to be rare in clusters. The exception would be cD galaxies which should lie at the centre of the density gradient and should not be significantly accelerated. Indeed, it seems bright straight doubles are rare in clusters, the exceptions being large centrally located cD galaxies.

Summary

We suggest that components of extended radio galaxies are merely plasmons, and that multiple ejections of these objects lead naturally to the observed structures of double-natured radio sources. The ram pressure deceleration of these objects (which for objects like Cyg A occurs at the end of a channel 'ploughed' by a previously ejected plasmon) leads to instabilities in the plasmon, which, far from destroying the plasmon, lead to *in situ* betatron and Fermi acceleration of the relativistic particles present in the plasmon. This acceleration provides a means of transforming a fraction of the tremendous bulk kinetic energy of the ejected plasmon into relativistic particle (and magnetic field) energy, thus producing the observed radio brightness. This replenishment of internal energy is necessary (and possibly sufficient) to explain the observed spectral and morphological features of extended radio sources.

Was there a late-Würm Arctic Ice Sheet?

T. Hughes & G. H. Denton

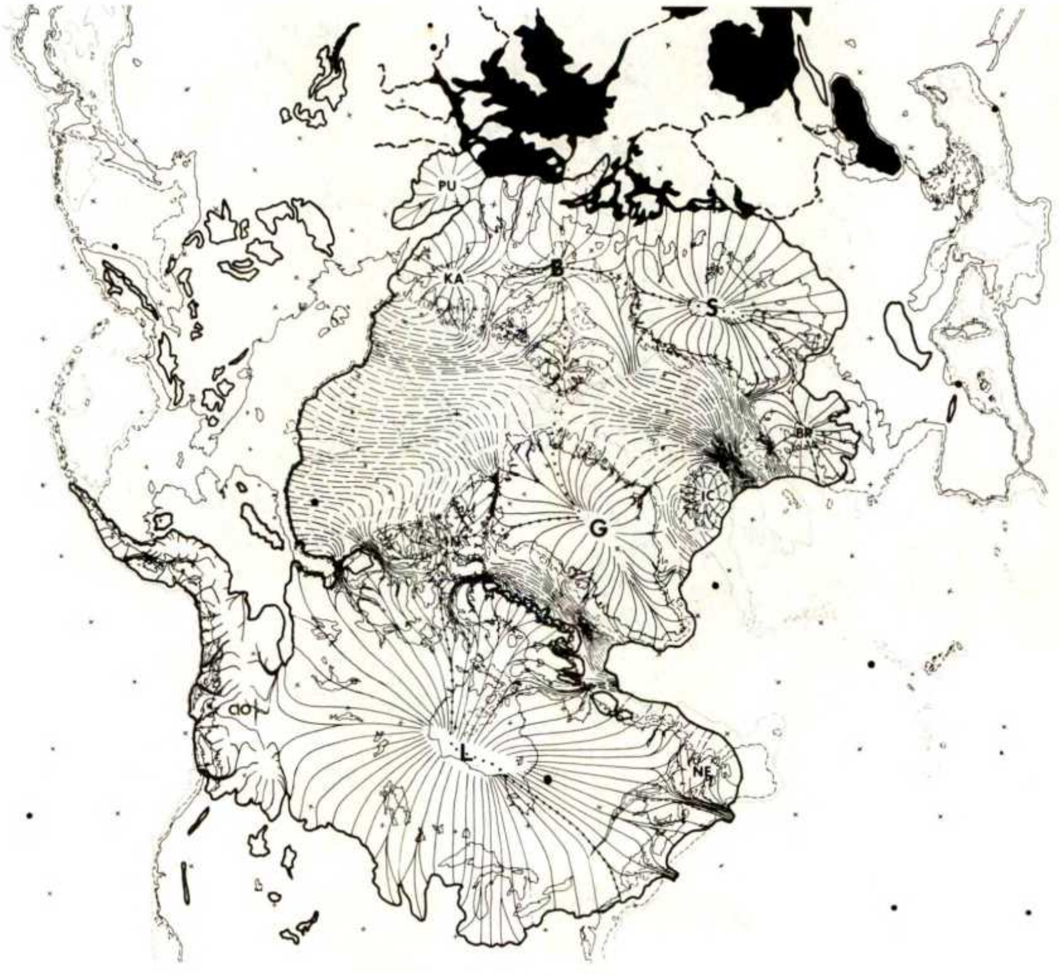
A simplification and synthesis of late-Würm Northern Hemisphere glaciation is possible by postulating an Arctic Ice Sheet that behaved as a single dynamic system.

LATE-WÜRM Arctic glaciation is better understood if we first identify the important features of present Antarctic glaciation. The Antarctic Ice Sheet is a mass of ice and snow covering most of the Antarctic continent, with both grounded and floating portions that are thick enough to flow under their own weight. Ice domes are centres of spreading in the grounded portions and are connected by ice divides. Terrestrial domes are grounded largely above sea level on the East Antarctic continental shield and marine domes are grounded largely below sea level on the West Antarctic continental shelf. Seaward flow from ice domes commonly converges on fast-moving currents of ice called ice streams. Ice streams draining terrestrial ice domes begin as outlet glaciers in fjords eroded through coastal mountains. Ice streams draining marine ice domes begin in submarine troughs eroded on the continental shelf. Ice streams are centres of spreading in the floating portion of an ice sheet, and form floating ice tongues that can coalesce with each other or with thick sea ice to create ice shelves; these are generally confined in embayments and pinned by islands or submarine rises. Calving bays form along the deep-water margin of the ice sheet where icebergs continuously calve from ice that is afloat or grounded well below sea level. Catastrophic retreat of a calving bay up an ice-stream occurs when the floating portion becomes unpinned and the grounded portion surges. A surge may be temporary, periodic or continuous, and is a sudden acceleration of glacial flow caused by substantial ice-bed uncoupling, resulting in massive fracture of the ice surface.

Conventional reconstructions[1] of late-Würm glaciation emphasise the terrestrial character of the Laurentide and Scandinavian ice domes, but when isostatic depression is considered, large portions of these domes were marine, as were the Innuitian, Barents Sea, Kara Sea and East Siberian Sea domes. We have now reconstructed all of the late-Würm ice domes (CLIMAP 18,000 BP revised ice-sheet reconstructions, unpublished data, University of Maine) and find that Weertman's[2] idealised two-dimensional analysis of an ice dome–ice shelf junction predicts that late-Würm marine domes may have been inherently unstable for present combinations of bed slope and sea level along flowlines of major ice streams that drained these ice domes. A conclusive demonstration of whether such instability existed would require a three-dimensional analysis that considers constraints imposed on ice streams by bedrock walls and sills, and constraints imposed on ice shelves by confining embayments and pinning points[2–5]. A preliminary analysis[6] indicates, however, that viscoplastic instability restricts the side-wall constraint on ice streams to a zone only a few kilometres wide, so that the major late-Würm ice streams should conform reasonably well to Weertman's two-dimensional

Fig. 1 A minimum reconstruction of the late-Würm Arctic Ice Sheet, in which an ice shelf covering the Arctic Ocean flowed from the Canadian-European sector to the Alaskan–Siberian sector, where it grounded along the continental-shelf margin and ablated slowly by melting. We assume that marine portions formed mainly from transgression of land portions on to continental shelves exposed by falling sea level. Present sea-level contour and present lacustrine shorelines — — —, Present 100-m bathymetric contour and a conservative late-Würm sea level contour . . . . . , Present 1000-m bathymetric contour and, except for island arcs and ocean ridges, the approximate continental-shelf margin, ———, Limit of late-Würm glaciation. ——— — —, Surface flowlines on the respective grounded and floating portions of the late-Würm Arctic Ice Sheet. L, Laurentide; G, Greenland; B, Barents; S, Scandinavian major domes of the Arctic Ice Sheet. IN, Innuitian; CO, Cordilleran; NE, Newfoundland; IC, Iceland; BR, British; PU, Putorana; KA, Kara; and (in Fig. 2) ES, East Siberian minor domes of the Arctic Ice Sheet. . . . . . , portion of the Arctic Ice Sheet that drained into the Atlantic Ocean. Regions flooded by ice-dammed rivers (black areas) include Mansi Lake in the Ob River basin, the Aral-Caspian Sea, and the Black Sea, which were 128 m above, 48 m above, and at least 50 m below present sea level, respectively, and were interconnected. +, Intersections of 10° longitude and latitude intervals.

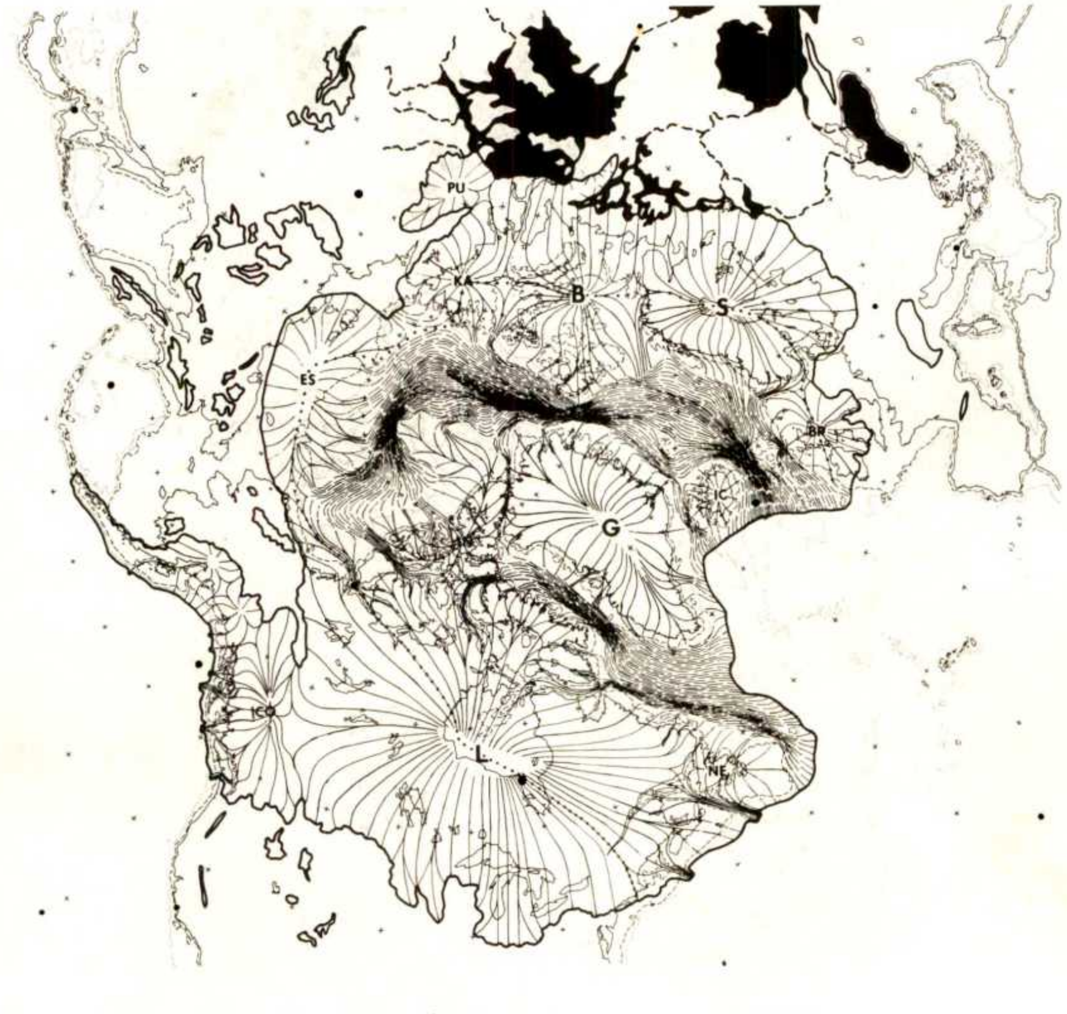


analysis. If so, the major constraint preventing disintegration of inherently unstable late-Würm marine ice domes was probably the inertia of confined and pinned ice shelves buttressing ice streams that drained marine ice domes. This hypothesis is supported by investigations of late-Würm recession of marine West Antarctic ice from the edge of the Antarctic continental shelf[2–9]. Today, this dome, which occupies less than half of its late-Würm area, is drained almost entirely by large ice streams that are usually buttressed by confined and pinned ice shelves. A dynamic argument can be made that removal of the ice shelves would lead to ice-stream surges[2–6], drawing down the ice dome and perhaps leading to its collapse by propagation of calving bays along evacuated ice-stream channels. Therefore, we conclude that reconstructions of late-Würm glaciers may have to consider the inertial constraint of confined and pinned ice shelves on ice streams that drained marine ice domes.

A second difficulty of standard reconstructions involves the chronology of late-Würm deglaciation. Available ^{14}C dates indicate major retreat of peripheral terrestrial ice early in the deglacial hemicycle as opposed to relatively late major recession of northerly marine ice. For example, considerable fluctuating recession began in the southern and western terrestrial Laurentide ice shortly after 18,000 yr ago, whereas major recession of northern Laurentide and Innuitian marine ice apparently did not begin until considerably later in the deglacial hemicycle. The reason for this is not obvious, particularly because the northern marine ice probably was unstable and because a glacial record from northern Alaska[10] suggests that late-Würm climatic amelioration was nearly synchronous in this portion of the Arctic and in temperate latitudes.

In view of these problems in dynamics and deglacial chronology, we think that a simplification and synthesis of late-Würm glaciation is possible by postulating an Arctic Ice Sheet that behaved as a single dynamic system composed of terrestrial and marine grounded ice, and ice shelves (Figs 1 and 2). We start by identifying numerous ice streams in marine portions of the Arctic Ice Sheet from geological literature and from continental-shelf topography. In order to buttress the largest ice streams, we endorse the concept of an ice shelf on the Arctic Ocean[11–13] and postulate extensions of this ice shelf across the Greenland, Norwegian and Labrador seas into the North Atlantic. Ice-shelf flow was determined by junctions of ice shelves with domes of the Arctic Ice Sheet. Two Arctic Ice Sheet reconstructions are presented because the distribution of late-Würm Arctic ice is not well known. In both the minimum (Fig. 1) and maximum (Fig. 2) reconstructions, the Greenland and Norwegian seas

Fig. 2 A maximum reconstruction of the late-Würm Arctic Ice Sheet, assuming marine portions formed mainly from thickening sea ice which became grounded on continental shelves. Markings are described in Fig. 1 legend. Compared with the minimum reconstruction in Fig. 1, the maximum reconstruction in Fig. 2 shows a hypothetical ice dome in the East Siberian Sea as an integral part of the Arctic Ice Sheet, an expanded Innuitian ice dome, and a more southerly position of the ice-shelf calving margin in the North Atlantic. These features greatly increased the area of the Arctic Ice Sheet that drained into the Atlantic Ocean. Circumstantial evidence for the hypothetical ice dome in the East Siberian Sea included the glaciated character of the De Long Islands, the presence of foreign till and erratics on the north coast of Alaska[14,15]; the truncated and dissected top of the Chukchi Cap[16]; and the topography of the sea floor in the area of Chukchi Cap, which appears glaciated and is very similar to sub-ice topography in East Antarctica (compare bathymetric contours of the Map of the Arctic Region, world 1 : 5,000,000 sheet 14, American Geographical Society, New York, 1975, with topographic contours under the East Antarctic Ice Sheet[17]).



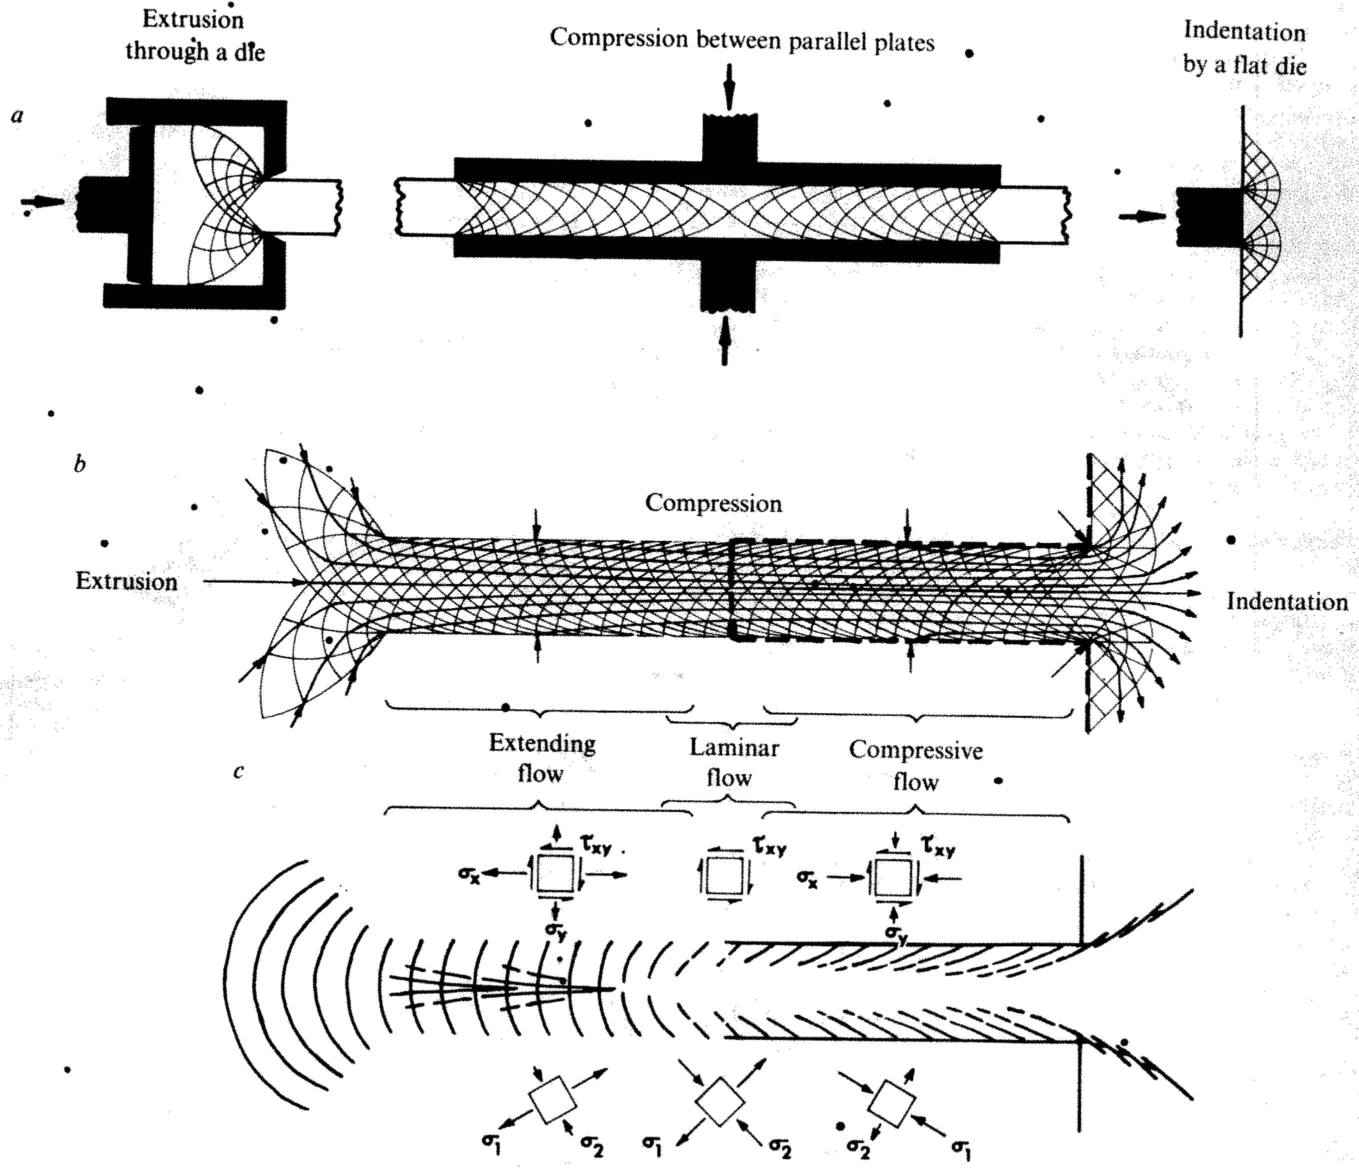


Fig. 3 The dynamics of ice streams draining marine portions of the Arctic Ice Sheet. The orthogonal slip-line fields of maximum shear stress for extrusion, compression and identation (*a*) can be joined to give the approximate slip-line field and flow lines for an ice stream (*b*) and to predict the expected crevasse pattern (*c*) when an ice stream is the major conduit for flow from an ice dome to an ice shelf. The channel eroded by an ice stream allows the ice dome–ice shelf junction (— — —) to extend part way up the ice stream. Flowlines (→) converge on fjords through the partly subglacial mountains bordering the continental shield at the head of an ice stream, and diverge on to the ice shelf bordering the continental shelf at the foot of an ice stream. Surface components of the stress tensor σ_{ij} and its principal stress components σ_k, shown on opposite sides of the ice stream, relate crevasses to extending, laminar and compressive flow as the ice stream becomes ungrounded and merges with the ice shelf. Removal of the ice shelf would bring the extending-flow regime to the foot of the ice stream, allowing a calving bay to migrate up the ice stream as icebergs are sectioned along extending-flow crevasses. Calving-bay migration would stop when the ice-stream grounding line reached a bedrock sill above sea level at the head of the fjord through the mountains, or would proceed into the heart of a marine ice dome if a sill did not exist.

were covered by a southward-moving ice shelf that was nearly grounded on the shallow banks between Greenland, Iceland, the Faeroe Islands and Scotland; and was fed from ice domes covering these areas, Scandinavia and the Barents Sea. Both reconstructions also show a southward-moving ice shelf over Baffin Bay, David Strait and the Labrador Sea, fed from the Laurentide, Innuitian and Greenland ice domes and nearly grounded in Davis Strait. The North Atlantic margin of the combined ice shelf extended in an arc from the Grand Banks off Newfoundland to the continental shelf off Scotland, coinciding approximately with the August 0 °C sea-level isotherm 18,000 yr ago[1]. This margin ablated largely by iceberg calving.

The importance of ice shelves to late-Würm glaciation is the recognition that a huge unbroken ice cover existed over polar seas and adjacent portions of North America, Greenland and Eurasia; that this ice cover constituted a unified Arctic Ice Sheet with grounded terrestrial and marine portions and floating ice shelves; and that all components were interconnected dynamically, each depending for its existence on the others. Late-Würm glacial history can be understood by viewing the Arctic Ice Sheet as one dynamic system, stressing the predominantly marine character of this system and the dynamics of marine ice domes in relation to ice streams, ice shelves, and calving bays. The huge interior floating ice shelves were key factors in stabilising the Arctic Ice Sheet, for they buttressed marine portions which in turn abutted terrestrial portions.

Ice domes

Our proposed Arctic Ice Sheet consisted of marine domes over Hudson Bay, the Gulf of Bothnia, the Barents Sea, the Kara Sea, the Queen Elizabeth Islands and possibly the East Siberian Sea; and terrestrial domes over the Canadian Cordillera, Newfoundland, Greenland, Iceland, the British Isles and the Putorana Plateau.

Seaward spreading from major domes of the Arctic Ice Sheet differed fundamentally from landward spreading: (1) It occurred primarily in marine portions over a bed that had been mostly below sea level, and which thus remained mostly thawed, whereas landward spreading occurred primarily in terrestrial portions over a bed that had been mostly above sea level and which had been and partly remained frozen. (2) Seaward spreading was primarily inward convergent flow from ice divides joining the domes, and thus accelerated more rapidly than landward spreading, which was primarily outward divergent flow from the ice divides. Because basal frictional heat increases as ice accelerates, more meltwater was formed at the bed for seaward than for landward spreading. (3) Seaward spreading ended as rapid stream flow because ice moved between coastal mountains and islands; landward spreading ended as slow sheet flow because ice moved over broad interior plains. Ice-sheet energy was thus focused on narrow zones along the seaward margin, but was dispersed across broad fronts along the landward margin. These features combined to increase ice-bed uncoupling, the primary cause of glacial surges, for seaward spreading compared with landward spreading. Surge conditions would thus develop first in ice streams and outlet glaciers draining marine portions of the Arctic Ice Sheet.

Ice streams

Mountain ranges along continental margins follow the landward side of the continental shelf and commonly project through an ice-dome margin. Hence, ice flowing seaward from the terrestrial portions of an ice dome commonly funnels into outlet glaciers that erode fjords through coastal mountains, and focus ice drainage in ice streams that erode troughs on the continental shelf. These ice streams are also supplied by the grounded marine portions of the ice dome. Ice-stream troughs are fore-deepened, as are fjords, so that a low submarine sill usually exists at the outer margin of the continental shelf where ice streams become afloat and merge with ice shelves. The sills and ice shelves combined to stabilise ice-stream grounding lines at many continental-shelf margins during the late-Würm. When ice-stream grounding lines retreated across these sills, they swept over the entire continental shelf and migrated into outlet-glacier fjords. We conclude that the ice streams draining the Arctic Ice Sheet were in stable equilibrium where they began as outlet glaciers, unstable equilibrium where they extended across continental shelves, and metastable equilibrium where they merged with floating ice shelves (Fig. 3). Constraints by thick ice shelves caused compressive flow, ice thickening and divergence where ice streams became afloat. This stabilised ice shelf–ice stream grounding lines at sills and bottlenecks associated with submarine banks along the outer continental-shelf margin. As soon as ice streams were able to punch through retreating ice shelves, however, the extending flow, ice thinning and convergence at the heads of ice streams became unchecked and caused grounding-line recession. The inherently unstable marine portions of the ice dome were then transformed into ice shelves and carved up by calving bays (Figs 3 and 4).

Mountains and islands along ice dome–ice shelf junctions in Antarctica are commonly unglaciated because outlet glaciers and ice streams tend to channel flow around elevated coastal topography. In our reconstruction, this implies that unglaciated portions[18,19] of Banks Island and Baffin Island, for example, are not indicative of thin inland ice, but result from channelling of sheet flow into fjords and straits, which allowed unglaciated highlands and headlands to exist along the ice dome–ice shelf junction. Ice streams similarly drained ice around Devon Island and Newfoundland, where local ice domes may have existed.

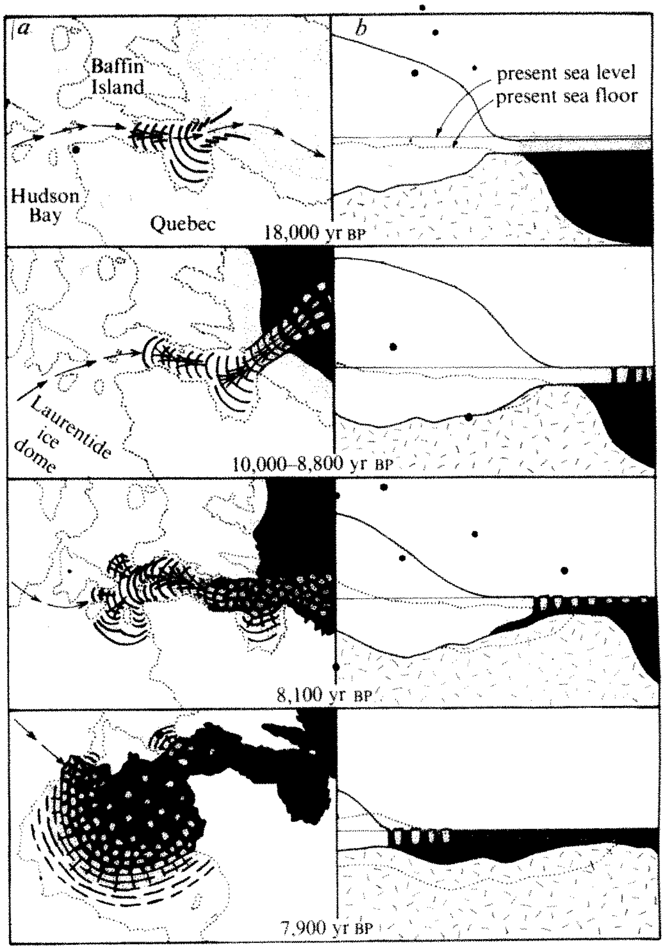

Fig. 4 Migration of a calving bay up the Hudson Strait ice stream and collapse of the Laurentide ice dome over Hudson Bay. Successive stages are shown in the plan (*a*) and profile (*b*) pairs, where the profile is taken along the ice flowline (→) shown in plan. White areas denote the grounded ice sheet, dotted areas denote the floating ice shelf and tabular icebergs, black areas denote seawater, and checked areas denote bedrock. In *a*: ...., present shorelines; ⌒ schematic crevasse patterns based on Fig. 3. The Hudson Strait ice stream was stabilised by an ice shelf in the Labrador Sea 18,000 yr ago. By about 8800–10,000 yr ago this ice shelf had retreated and thinned sufficiently for the ice stream to punch through it between the longitudinal-shear crevasses along its floating length so that a calving bay followed the ice stream grounding line up Hudson Strait. The Laurentide ice dome collapsed in a few centuries after the grounding line and calving margin of the surging ice stream crossed the island pinning points at the entrance to Hudson Bay.

Ice shelves

What maintained the stability of the large floating ice shelves that may have been necessary to prevent ice streams from drawing down marine portions of the Arctic Ice Sheet? One requirement is that a positive mass balance existed over all but calving and melting margins of the ice shelves. In the Arctic Ocean a positive annual mass balance would have been expected once northward heat transport from the North Atlantic Current essentially ceased[20] during the late-Würm maximum, when the North Atlantic Current flowed eastward towards Africa rather than north-eastward into the Norwegian Sea[21]. This change in current direction caused lower North Atlantic sea-surface temperatures so that they were compatible with an ice shelf that had a snowline close to sea level along its North Atlantic calving margin.

A second requirement is that snow accumulation over the Arctic Ice Sheet was sufficient to maintain the iceberg calving rate, which can be estimated from present Antarctic ice shelves, along the North Atlantic ice-shelf margin. The nearly constant forward velocity about 100 km behind the calving margin of the Ross Ice Shelf is about 0.9 km yr^{-1} (ref. 22), and seems to

Table 1 Ice-accumulation rates on the Arctic Ice Sheet necessary to maintain a 900 m yr^{-1} iceberg calving rate in the North Atlantic

Area of accumulation basin (km^2)	7.73×10^6	15.87×10^6
Mean accumulation in basin (m yr^{-1})	0.053	0.076

equal the iceberg calving rate because the calving margin has not undergone substantial change in this century. The nearly constant forward velocity of the Ross Ice Shelf was measured for ice averaging 350 m thick across an unsupported front 600 km wide between Roosevelt Island and Ross Island. Presumably, a forward velocity of about 0.9 km yr^{-1} would also be required 100 km behind the calving margin of the late-Würm North Atlantic ice shelf, if its forward velocity matched the estimated present Ross Ice Shelf iceberg calving rate. Sectors between pinning points along the Labrador–Baffin–Greenland–Iceland–Faeroe–Scotland line varied from 70 to 350 km wide. Ice > 350 m thick in any sector along this line would have been grounded (Table 1). Annual precipitation rates needed to maintain a 0.9-km yr^{-1} ice-shelf velocity across each sector are given in Table 1 (where the flowlines in Figs 1 and 2 are used to identify the snow accumulation basins for each sector) and are well below present rates in high polar regions, suggesting that the postulated calving rates could have been maintained easily. Hence, we think that late-Würm ice shelves existed over polar seas and stabilised the Arctic Ice Sheet.

Although the probable need to stabilise large ice streams that drained marine portions of the Arctic Ice Sheet is our primary reason for reconstructing ice shelves, other evidence is compatible with this postulate. Like present Antarctic ice shelves, our proposed Arctic ice shelves all existed in embayments nearly surrounded by large ice domes and had margins that were pinned by islands or banks. Glacial-marine sediments with very low abundance of left-coiling *Globigerina pachyderma* deposited in the Norwegian and Greenland seas during the late-Würm maximum indicate absence of the North Atlantic Current and presence of a complete ice cover[23]. Late-Würm sea-surface temperatures in the North Atlantic were compatible with an ice-shelf calving margin between Newfoundland and Scotland[1]. Nothing yet reported from the Arctic Ocean floor precludes existence of a late-Würm ice shelf; whereas slow sedimentation rates, striated clasts and truncated rises on this ocean floor are compatible with a debris-carrying ice shelf slowly ablating on its underside and scraping across pinning points[24–26].

Calving bays

We postulate that dynamic processes involving ice streams, ice shelves and calving bays were essential factors in disintegration of marine portions of the Arctic Ice Sheet. Calving bays have an important role in removing ice rapidly, and exist in metastable equilibrium. That is, they are in stable steady state for small perturbations that do not permit ice-shelf grounding lines to migrate over bedrock sills or ice-shelf calving margins to retreat from pinning points, but are in unstable catastrophic retreat for large perturbations that allow either of these events to occur. Hence, calving bays can remove floating ice shelves, or can disintegrate grounded marine ice by propagating up surging ice streams that have punched through buttressing ice shelves (Figs 3 and 4).

A view of Northern Hemisphere deglaciation that involves these dynamics is now possible. The Arctic Ice Sheet underwent peripheral fluctuations between about 22,000 and 14,000 yr ago. It then suffered step-by-step collapse of its marine portions concurrently with slow ablation of its terrestrial fringes. First, rising air temperatures and northward migration of the North Atlantic Current ablated the North Atlantic ice-shelf calving margin from pinning points between Iceland and Scotland shortly before 14,000 yr ago[21], causing ice-shelf recession into the Norwegian Sea. Late-Würm Scandinavian ice had extended to the edge of the Norwegian continental shelf, where it terminated in water that was commonly up to 450 m deep[27,28]. The topography of the Norwegian continental shelf[27,28] indicates to us that outlet glaciers from the Scandinavian dome continued across the continental shelf as ice streams up to 250 km long. If so, we would argue from the viewpoint of ice stream–ice shelf dynamics that the Norwegian Sea ice shelf buttressed these ice streams, and ice streams from the Norwegian Trench, the Barents Sea dome, and the Icelandic dome. In this case, the broad Egga moraines would have been deposited at the ice dome–ice shelf junction. Ice-shelf recession into the Norwegian Sea about 14,000 yr ago would have unbuttressed the ice streams, causing surges and resulting in rapid removal of marine ice from adjacent continental shelves by calving bays. This is compatible with the distribution and age of the oldest late-Würm moraines on the outer Norwegian and Icelandic coasts[29–32]. Whether the Barents Sea dome receded at this time is unclear. Shell ^{14}C dates from emerged marine deposits imply that major recession of Barents Sea ice occurred relatively late[33], which is compatible with ^{14}C dates of the Marchida moraines in north-western USSR that place final disintegration of eastern Barents Sea ice in Pre-Boreal time[34]. New dates on shells from the westernmost coast of west Spitsbergen, however, if they are reliable, suggest that initial deglaciation of western Barents Sea ice may have been earlier than previously expected (G. Boulton, personal communication, 1975). In any case, we postulate that subsequent north-westward recession of the Norwegian Sea calving bay into the Greenland Sea would have removed grounded ice from the East Greenland continental shelf. Finally, the heart of the Scandinavian ice sheet was removed by a calving bay that migrated up the region now covered by the Baltic Sea and the Gulf of Bothnia. The Gulf of Bothnia was deglaciated by 9300–8900 yr ago[35,36].

Late-Würm climatic amelioration also caused the ice shelf over the Arctic Ocean to unground north of Alaska and to retreat toward Siberia and Greenland, resulting in step-by-step surges of northern Laurentide, Siberian and Innuitian ice streams. Deglaciation of northern Laurentide ice probably occurred largely by calving bay propagation up these surging ice streams. It had begun by 12,400 yr ago on north-western Victoria Island[37]; by 10,500 yr ago in Dolphin and Union Straits, and by 10,200 yr ago in Coronation Gulf. As late as 10,000 yr ago, however, a Laurentide–Innuitian ice lobe still occupied Viscount Melville Sound. Ice recession occurred in Parry Channel between the Laurentide and Innuitian domes by 9500–9000 yr ago, allowing deglaciation of McClintock Channel and Peel Sound by 9200 yr ago[38–40].

Recession of westernmost Innuitian ice from Prince Patrick Island had begun by 11,700 yr ago and from Melville Island by 11,300 yr ago. Deglaciation of the inner channels under the Innuitian dome occurred 10,000–9000 yr ago[40]. Meanwhile, the Labrador Sea calving bay had migrated past pinning points in Davis Strait and retreated into Baffin Bay by 10,000–9000 yr ago[41–45], then up Hudson Strait, past the island pinning points at the north end of Hudson Bay, and gutted out the remainder of the Laurentide ice dome about 8100–7900 yr ago (Fig. 4). Finally, a calving bay migrated into Foxe Basin shortly after 7000 yr ago[46]. The hearts of most major domes of the Arctic Ice Sheet were thus removed, in some cases leaving terrestrial fringes to ablate by melting. The Greenland dome still remains in existence, because it alone among the major domes was largely terrestrial and therefore immune to irreversible disintegration mechanisms affecting marine ice domes.

Conclusions

We believe that the concept of an Arctic Ice Sheet harmonises geological and glaciological problems associated with standard reconstructions. It fits the pattern of deglaciation and reconciles the problem of initial major recession of peripheral terrestrial portions as opposed to later major retreat of interior marine portions. It conforms with the dynamic relationship of grounded marine ice to ice streams and ice shelves that we postulate for the present marine West Antarctic ice dome[7–9]. Moreover, it emphasises that the Arctic Ice Sheet consisted of marine portions in unstable equilibrium confined between land portions in stable equilibrium and ice shelves in metastable equilibrium. Perturbations of stable sectors were reversible, perturbations of unstable sectors were irreversible, and perturbations of metastable sectors were reversible if small, but irreversible if large. The critical perturbations during the last 14,000 yr were intervals of climatic warming that affected the margins of the Arctic Ice Sheet. These perturbations were reversible along terrestrial margins in stable equilibrium, but were large enough to be irreversible along ice-shelf margins in metastable equilibrium. Terrestrial portions retreated slowly across wide fronts by melting. Marine portions that had been in unstable equilibrium collapsed by rapid inroads of calving bays which migrated up surging ice streams after climatic warming removed the confined and pinned ice shelves which had prevented ice-stream surges. Cryosphere–hydrosphere interactions thus destroyed the marine heart of the Arctic Ice Sheet, whereas cryosphere–atmosphere interactions eliminated terrestrial fringes.

Implicit in our Arctic Ice Sheet hypothesis is the suggestion that ice shelves formed before marine portions of the ice sheet. Otherwise, these marine portions, being inherently unstable, might never have existed. The implications of this suggestion will be presented in a later publication.

DNA sequences coding for the H2B histone of *Psammechinus miliaris*

M. L. Birnstiel*†, W. Schaffner*‡ & H. O. Smith†

*Institut für Molekularbiologie II der Universität Zürich Winterthurerstr. 266A, 8057 Zürich, Switzerland.

‡MRC Laboratory of Molecular Biology, University Postgraduate Medical School, Hills Road, Cambridge, UK.

Starting from restriction enzyme cleavage sites of known topologies the DNA sequences coding for two thirds of the H2B histone protein, together with some 3′ extracistronic sequences, have been determined for the sea urchin Psammechinus miliaris. *This unambiguously identifies this gene and further reveals its 5′–3′ polarity and accurate map position in a cloned histone DNA repeat unit.*

THE coding sequences of the five histone proteins are arranged[1] in the order H4, H2B, H3, H2A and H1 in a 5.6–6 kb DNA repeat unit[1,2] which is many hundred times repeated on the chromosomal DNA of *Psammechinus miliaris*[3], the first species for which the exact gene order[1] and the direction of transcription[4] unravelled. It now seems that an identical gene arrangement is found for *Strongylocentrotus* histone DNA[5,6], while unpublished work from Hogness' laboratory and our own (Jean Burckhardt) suggests that the histone genes in *Drosophila* are organised differently. Here we report the base sequence arrangement of two sections of the H2B coding sequence of the histone DNA isolated[7] from the λ-histone phage λh22 with essentially three aims in mind.

(1) To test the identification and map position of the H2B coding sequence, formerly obtained by hybridisation of the putative H2B mRNA to histone DNA[8].
(2) To verify the polarity of the H2B gene, and hence of the gene cluster, as previously determined from a combination of resection with 5′ exonuclease and hybridisation with individual mRNAs to histone DNA[4].
(3) To confirm the accuracy of partial denaturation mapping of genes and spacers in the electron microscope[2].

These studies will also enable us to gain new insights into the evolution of the H2B proteins and to assess the fidelity of sequence conservation during maintenance and amplification of histone DNA cloned in a lambda vector.

Sequencing procedures

Both the sequencing techniques[9,10] used for these experiments depend on the availability of restriction cleavage sites as unique starting points for the actual sequence analysis.

Figure 1*a* depicts the structural map of the *Psammechinus* histone gene cluster as it was compiled from biochemical[11] and electron microscopic[2] analyses. The histone DNA, reclaimed from λh22 accommodates five (possibly six; see below) cleavage sites for the restriction enzyme *Hin*dII, as indicated on the map. The fragments A, C and F produced by this treatment can be further cleaved asymmetrically by digestion of the DNA with restriction enzymes *Hae* II and *Bgl* II (see Fig. 2). Two of these restriction fragments (fragments 2 and 4) terminate in close proximity to one another in the DNA segment predicted to contain the H2B sequences. The termini of these DNA fragments, with their well defined locations within the histone DNA provide suitable starting points for the sequencing of the H2B gene. Moreover, fragment B can be strand separated by gel electrophoresis[9] and subjected to sequence analysis.

Histone DNA (25 μg), prepared from λh22 recombinant DNA by cleavage with *Hin*dIII followed by purification from λDHA by two cycles of actinomycin CsCl density gradient centrifugation[12] was digested with 50 units *Hin*dII enzyme for 3 h in 50 μl buffer containing 20 mM Tris-HCl, *p*H 7.8; 7 mM $MgCl_2$, 7 mM mercaptoethanol. At the end of the incubation 1 μl BAP (0.06 U) was added. Incubation was continued for 30 min at

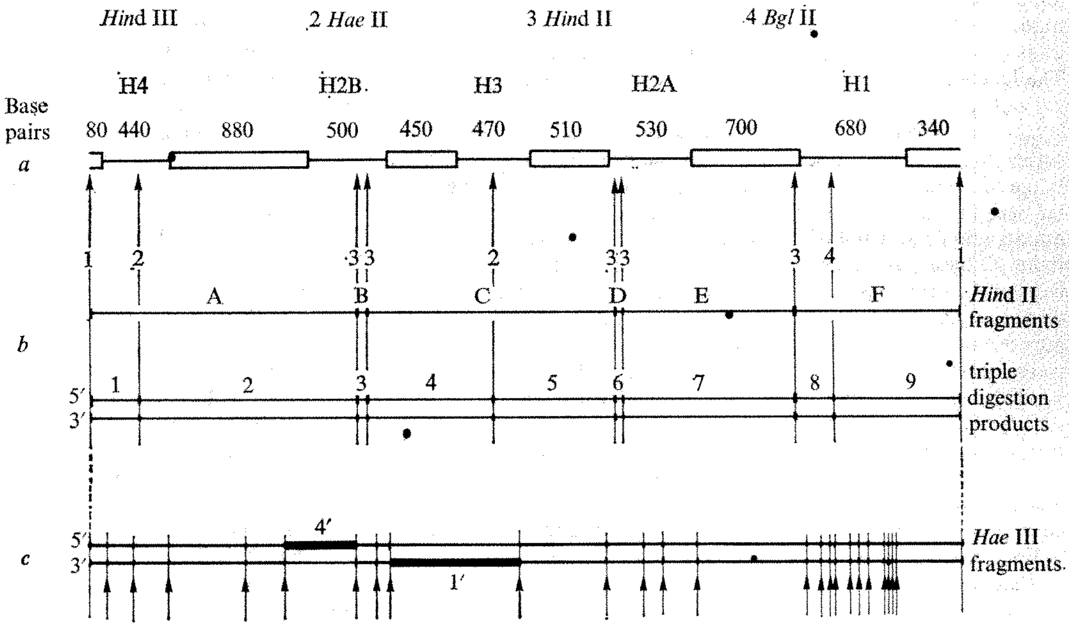

Fig. 1 Partial denaturation and restriction maps of histone DNA reclaimed from λ h22 recombinants. *a*, Distribution of spacers (double line) and histone mRNA coding sequences as determined in the electron microscope[2]. *b*, Cleavage sites for restriction enzymes *Hind* III, *Hae* II, *Hind* II and *Bgl* II (see text). *c*, Cleavage sites for *Hae* III. Fragments 2 and 4 and 1′ and 4′ were used in the sequencing experiments.

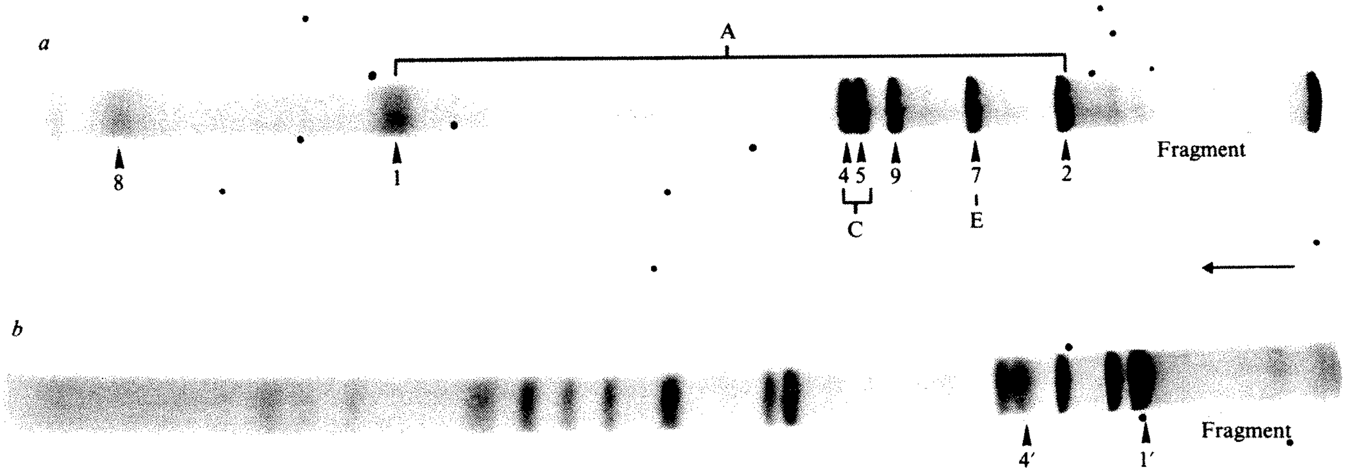

Fig. 2 Restriction fragments of cloned histone DNA h22. *a*, Electropherogramme of fragments produced after digestion of cloned histone DNA with *Hae* II, *Hin*d II and *Bgl* II. Electrophoresis was through a 4% polyacrylamide gel in 90 mM Tris; 90 mM Borate, *p*H 8.3; 2.5 mM EDTA at 4 V cm^{-1}. The fragments refer to the DNA sections shown in Fig. 1*b*. Fragments 2 and 4, labelled at only one of their termini with (γ-^{32}P)-ATP were subjected to the sequencing technique of Gilbert and Maxam[9]. *b*, *Hae* III restriction fragments of cloned histone DNA, Electrophoresis was as described above. Fragments 1′ and 4′ were recovered and annealed to strand separated γh22 DNA and served as primer for the 'plus and minus' technique[10]. For strand separation of histone recombinant phage DNA the procedure of Szybalski[14] as modified by Lozeron (W. Barnes, Ph.D. thesis) was used. One mg purified λ Sam-7 h22 (ref. 7) dissolved in 3 ml of 1 mM KH_2PO_4; 1 mM EDTA; *p*H 8.5; 0.1% sodium sarkosyl was mixed with 0.66 mg of poly (U, G) (Miles) and was denatured for 3 min at 100 °C. After quick chilling, 60 µl of 50 mM Tris-HCl, *p*H 7.6 was added and the solution made up with CsCl and water to a final vol of 16.8 ml and a density of 1.750 g ml^{-1}. The solution was transferred to a polyallomer centrifuge tube which had been previously boiled in 0.1 M EDTA, *p*H 10 and was centrifuged at 32,000 r.p.m. for 60 h at 20 °C in a Ti60 rotor. 40 fractions were collected, and the distribution of the separate DNA strands monitored either by absorbance measurements or by analytical agarose gel electrophoresis. Fractions corresponding to the heavy and the light strand were individually pooled and dialysed against 5 mM Tris-HCl, *p*H 8. Poly (U, G) was removed by incubating the samples in 0.5N NaOH at room temperature for 1 h. Tris-HCl and HCl were added to an end concentration of 0.3 M NaCl; 0.3 M Tris-HCl, *p*H 7.8 and the strands were self-annealed at 65 °C for 1 h. The DNA was then precipitated by addition of ethanol and redissolved in 300 µl 10 mM Tris-HCl, *p*H 7.5; 0.5 mM EDTA and the solution at about 0.8 mg ml^{-1} kept frozen. For one 'plus and minus' sequencing reaction, 10 µg of restriction fragment (about 1 pmol) was denatured in a boiling waterbath for 3 min, chilled in ice, mixed with about 8 µg of single stranded lambda DNA prepared as described above (about 0.5 pmol) and allowed to anneal at 67 °C for 1 h in 0.1 M NaCl; 20 mM Tris-HCl, *p*H 7.4; 10 mM $MgCl_2$, 1 mM mercaptoethanol. This material could then be used directly for elongation by DNA polymerase using the Sanger and Coulson technique[10].

37 °C. The DNA was deproteinised by shaking with phenol and was recovered by precipitation with ethanol. After washing with ethanol, the DNA was redissolved in 100 µl kinase buffer (50 mM Tris-HCl, *p*H 9.5; 0.01 M $MgCl_2$; 0.005 M DTT; 5% glycerol) to which 10 µl of (α-P^{32}-)ATP (10 µM; 1,000 Ci mmol^{-1}) made up according to the protocol of Gilbert and Maxam[9], and 1 µl T_4 kinase (0.5 U) were added. After 15 min 2 volumes of 2 M ammonium acetate were added and the DNA was precipitated with 21/2 volumes of ethanol. The DNA was recovered by centrifugation, dissolved in 100 µl 10 mM Tris-HCl, *p*H 7.8; 1 mM EDTA and loaded on a 0.2 × 15 × 40-cm 4% polyacrylamide gel made up in glycine buffer (30 ml NAOH; 30 g glycine made up to 2 l.). Electrophoresis was terminated when the unincorporated ^{32}P appeared in a lower buffer compartment. The labelled DNA bands were located by autoradiography and cut out from the gel.

The polyacrylamide gel revealed seven kinds of molecules rather than the five anticipated from the previous work[11]. The two additional cleavage products were found in the low molecular weight range. One of these, B, bridges the gap between amino acid 85 and 104 of the H2B sequence and thus is made up from 62 base pairs (see below). The nature of the other small fragment, which was only poorly labelled, has not been determined as yet. The two slowest moving components of the polyacrylamide gels corresponding to fragments A and C of Fig. 1*a* were recovered, pooled and digested with *Hae* II. This treatment yielded four DNA molecules each labelled with ^{32}P at one of their ends. Fragments 2 and 4 (see Fig. 1*a* and 2) containing the presumptive H2B DNA sequences were then subjected to the sequencing procedure of Gilbert and Maxam[9]. In addition, fragment B was recovered, denatured and strand separated by electrophoresis and the faster moving single strand sequenced[9].

For other sections of the histone DNA, the plus and minus method of Sanger and Coulson[10] was used. This procedure is based on elongation by DNA polymerase of unique primer DNA fragments hybridised to a single stranded template DNA. The availability of histone DNA cloned both in lambda[7] and in pCRI plasmid[13] proved to be very advantageous for this work. Template was obtained in preparative amounts by strand separation of histone recombinant DNA with poly(U, G) in a CsCl density gradient according to the protocol of Szybalski *et al.*[14]. Primer fragments were prepared by restriction of total recombinant pCRI h7 DNA and fractionation of the products by preparative polyacrylamide gel electrophoresis. This combination of template and primer DNA each obtained using different vectors eliminated any possible vector DNA background during sequencing.

For the preparation of primer DNA, 600 µg of the recombinant plasmid pCRI (Pm histone) 7 DNA[13] were cleaved with *Hae*III restriction endonuclease (a gift of Dr Nigel Brown) and the resulting fragments were fractionated on a 0.3 × 20 × 45 cm, 5% polyacrylamide slab gel[9]. Then 2 µg of reclaimed 6kb *Psammechinus* histone repeat, digested with *Hae* III, were run in parallel slots in order to identify the histone-specific DNA fragments. The gel was immersed for 1 h in electrophoresis buffer containing ethidium bromide 0.5 µg ml^{-1}. Histone DNA fragments were excised under ultraviolet light. The DNA was recovered by electrophoresis into a dialysis bag, taken up in 0.3 M sodium acetate, *p*H 7, mixed with 21/2 volumes of ethanol, kept at −20 °C overnight and spun down in a SW50 rotor at 45000 r.p.m. for 1 h at 4 °C. The DNA fragments were redissolved in 200 µl 10 mM Tris-HCl, *p*H 7.5; 0.5 mM EDTA and kept frozen until use.

The *Hae* III fragments have been mapped (see ref. 11, and Figs 1*c* and 2). The largest of these (1′) includes the spacer between the H2B and the H3 gene and part of the latter. This DNA section and 9 other *Hae* III DNA fragments were isolated (see above) and on denaturation were individually annealed to either the light or the heavy strand of λh22 DNA known to contain the coding and the anti-coding sequence of the histone

Fig. 3 DNA sequences of H2B histone protein. Protein sequence of H2B of *Parechinus* (top line, ref. 15) of calf thymus (bottom line, ref. 16); middle line—DNA and protein sequences of the H2B of *Psammechinus*. Amino acids in *Psammechinus* which differ from either of the other two species are marked with asterisks. Ambiguities in either DNA or protein sequences are denoted by brackets. The restriction cleavage sites relevant to the present work are boxed.

mRNAs, respectively (see Fig. 2 legend). After base sequence analysis, the DNA sequences were converted into amino acid sequences using all three possible reading frames and compared with the known amino acid sequences of the histone proteins by computer. Sequences pertaining to the H2B were identified by comparison with the known H2B protein sequence of the sea urchin *Parechinus*, determined by Strickland and von Holt[15].

Partial sequence of the H2B gene of *Psammechinus*

The H2B protein from the sperm of the sea urchin *Parechinus* contains 143 amino acids[15]. Comparison with the calf thymus protein revealed[16] that the *Parechinus* sperm protein is larger by 17 amino acids, with the additional peptide sequences appearing, in the main, at the N-terminal end of the molecule. The DNA sequences obtained from the base sequence analysis of the *Psammechinus* histone DNA were converted into amino acid sequences and recorded in Fig. 3 so as to yield maximal sequence homology with the H2B protein of *Parechinus* (top line) and calf thymus (bottom line), respectively. The numbering of the amino acids of the *Psammechinus* protein was made to conform with that of *Parechinus*. Starting at the 5′ terminus of fragment 2 (Fig. 1) the Gilbert and Maxam procedure yielded about 75 bases of the coding sequence, from approximately amino acid 84 to amino acid 60. Starting from the labelled *Hin*dII site of fragment 4 a sequence of 80 nucleotides was obtained, representing the anti-coding sequence ranging from amino acid 107 up to 131 of the H2B protein. In this experiment, the first two or three bases were lost from the analysis so that the known sequence started at Val (position 107). The position of the *Hin*dII cleavage site may be predicted from the amino acid sequence of the protein, as indicated in Fig. 3. The fast-moving single strand of B yielded the coding sequences for codons 104 to 90, leaving a gap of a few amino acids unaccounted for.

Comparison of the H2B amino acid sequences and the DNA sequence obtained from hybridisation of one of the smaller *Hae* III fragments (indicated in Fig. 1*c* as a bold line) to the light strand of λh22 DNA and subsequent sequence analysis using the plus and minus method[10] showed that this section contained the missing DNA sequence between amino acid positions 85 and 90. The first readable codon specified Ser in position 82 and could be extended up to amino acid 91. Here too, there was a small overlap in DNA sequence in both sets of experiments. From the position of the first readable codon 82 on the electrophoretic gel relative to the dye marker it was predicted that the *Hae* III sequence which had served as a primer for strand extension, was to be found some 18 base pairs to the left of codon 82. As can be seen from the first set of data, it lies at the predicted point between Arg 75 and Ala 76.

From the mapping experiments (Fig. 1*c*) it was also predicted that the large *Hae* III fragment used in these experiments encompasses most of the spacer region between the H2B and H3 gene, with a *Hae* III site just to the right of the former. Strand extension starting from the fragment annealed to the heavy λh22 strand was expected to include the coding sequence of the C-terminal end of the H2B protein. Comparison of the DNA and protein sequences has confirmed this. The sequence contains, in addition to a short stretch of DNA, presumably coding for an untranslated region of the H2B mRNA, about 45 readable bases extending to His 127. Here again there is a small overlap of 15 bases with the previous set of data. Our data then, covering the proteins sequences from amino acid 60 to 143 provide an unequivocal identification of the H2B gene confirming our results previously obtained by the classical methods of mRNA translation *in vitro*[8] and RNA–DNA hybridisation[1].

A small number of ambiguities in the DNA sequences and hence in the amino acid assignments remain. These have been noted in Fig. 3.

Polarity and map position of the H2B coding sequence

The positions of the *Hin*dII and the *Hae* II cleavage sites have been determined independently from overlaps found in complete digests using a variety of restriction enzymes or by our partial enzyme digestion procedure (Fig. 1). In these experiments it was established that fragment A is cleaved asymmetrically by *Hae* II so that the terminus on the left of the map becomes associated with the small DNA fragment 1 and the other terminus with fragment 2. Moving from the ^{32}P-labelled 5′ end of fragment 2 towards the left (Fig. 1*a*), a partial sequence of the H2B coding sequence was obtained. In turn, the ^{32}P-labelled 5′ terminus of fragment 4 yielded the anti-coding sequence of the H2B from amino acid 107 to 131. Also, *Hae* III fragment annealed to the light and another small fragment annealed to the heavy λh22 DNA yielded upon extension of the 3′ termini with polymerase anti-coding and coding sequences of the H2B, respectively. Together, these experiments prove unequivocally that the lower strand (Fig. 1*b* and *c*) includes the coding sequence and hence these experiments confirm that transcription of H2B is from the left to right of the map—as shown for the histone DNA repeat unit by exonuclease experiments[4].

The present work can also be used to place the H2B coding sequence accurately in the partial denaturation map of cloned histone DNA. Electron microscope mapping studies revealed that the *Hin*dII enzyme cleaves the double-stranded DNA region presumed to represent the H2B gene[2] in the right half of that DNA segment. Our present work shows that there are in fact two *Hin*dII sites in close proximity to one another at positions 85 and 105, about two thirds of the way along the H2B sequence. The *Hae* III sites predicted to lie in the same area (see Fig. 1*c*) have now been mapped, by sequencing, near Ala 76 and 125, respectively. It should be mentioned, that the largest *Hae* III fragment has been shown, by sequence analysis, to extend into the H3 coding sequences to the right. Furthermore, the N-terminal end of the H2A coding sequence has been located using another *Hae* III fragment of known map position, so that this coding sequence also has been identified and mapped unequivocally within the cloned histone DNA of *Psammechinus* W. S. and M. B., unpublished). Our sequencing data therfore confirm our previous assignments of genes[1,7] as well as their positions in relation to spacer DNA[2]. Nothing can as yet be said about the extracistronic sequences since they show no homologies to known untranslated mRNA sequences.

Evolution of the H2B protein sequences

The available DNA sequences define about two thirds of the amino acid moieties of the H2B protein of *Psammechinus*. There is extensive sequence homology with both the calf thymus and the sea urchin *Paraechinus* H2B protein, especially near the C terminus. This is in keeping with the general tenet that histones are conservative in evolution. There are some disparities, however. Thus position 78 and 100 are different in all three proteins. Two substitutions Arg⇌Lys occur in positions 75 and 143. Val in position 142 apparently is different from the Ser in either of the two other proteins. There is a whole series of interchanges involving Val⇌Ile. It should be noted that, with two exceptions, all amino acid substitutions are conservative and must therefore be the result of natural selection acting at the level of protein sequence within the living animal. This suggests that the change we observe reflects the evolution of the H2B sequences within the sea urchin rather than a randomisation process which might have occurred during cloning and amplification of the histone DNA in a lambda vector, and further supports the hypothesis that the cloned histone DNA has remained essentially unaltered after passage through *E. coli*.

We have asked whether the frequent substitutions Val⇌Ile could be neutral mutations occurring by a random process. In this context it is pertinent to note that the codons in region 62, 66, 72, 79, 84, 87, 91, 107 and 112 are such that interconversion of these two amino acids could occur by substitution of a single base G⇌A. If the appearance of A or G in the first position was determined purely by chance, there would be a 1 : 8 probability of finding only Val at a given position in all three species, a 1 : 8 chance of finding only Ile and a 6 : 8 probability of finding a mixture of the two. In the nine instances cited above the frequency of occurrence of Val only, Ile only or Val and Ile mixed at a given site in the three species are 3 : 9, 2 : 9 and 4 : 9, respectively. These ratios are distinctly different from those expected from a stochastic process and the appearance, in many instances, of Val only, or Ile only, must be the result of natural selection at the protein level.

Considering only amino acids which have been unequivocally identified, the known sequence of *Psammechinus* differs from that of *Parechinus* in overall nine moieties, but only in seven from calf thymus H2B; while the work of the von Holt group[15] has shown the calf thymus and *Parechinus* sperm H2B to differ in 11 amino acids within the sequences delimited by the present work. The known *Psammechinus* H2B sequences are more like those of calf thymus H2B than those of *Parechinus* sperm. Now, the H2B histones of sea urchins are a diverse class of proteins giving rise to variants[17] which are often associated with tissue-specific gene expression. Interestingly, H2B proteins isolated from *Parechinus embryos* are more like calf thymus H2B (von Holt, personal communication) and so it is possibile that the histone DNA clone we are analysing is derived from those gene units which would normally have been active during early stages of sea urchin development.

We thank Drs F. Sanger, M. Smith and N. L. Brown for instruction and hospitality during the stay of W.S. in Cambridge, England, and Mr K. J. Rüegg, ETH Zürich, for the development of computer programs. We also thank Professor von Holt for making protein sequence information available before publication, and John Telford, Edith Bohl, Arlette Binkert and Dr Margaret Chipchase for assistance. H.O.S. was supported by the Roche Research Foundation, and W.S. received an EMBO Short Term Fellowship. The work was supported by the Schweiz. Nationalfonds, the State of Zürich, and by the US Public Health Service.

letters to nature

A galactic vacuum cleaner?

A REMARKABLE feature of the distributions of CO, H_2, HI, HII and dust in the Galaxy is that their most dense regions form a broad ring-like structure surrounding the galactic centre, along with a dense nuclear disk located at the centre[1–4]. Between the ring and the nuclear disk there exists a region of very low density. The radius of the nuclear disk is approximately 600 pc, and the ring extends from an inner radius of 2–4 kpc out to a radius greater than 15 kpc for HI, but to only 8–10 kpc for the interstellar components expected to be generated by spiral shocks (namely CO, H_2 and HII). We point out here that this structure is a possible consequence of a postulated stellar bar at the centre of the galaxy.

The difference between the HI ring and that of the other components can be explained in terms of the radial variation of the spiral shock strength, and this idea forms the basis of Stecker's recent proposal for modifying the galactic population classes[5]. The shock strength is an increasing function of the component of the gas velocity perpendicular to the assumed spiral stellar potential, namely $r(\Omega-\Omega_p)\sin i$, where r is the galactocentric radius, Ω and Ω_p are the angular velocities of the gas and spiral pattern respectively, and i is the spiral pitch angle. One way in which the shock strength could decrease to zero at 8–10 kpc, and hence explain the confinement of CO, H_2 and HII to within that radius, is for corotation ($\Omega = \Omega_p$) to occur at around 10 kpc. This would require $\Omega_p \approx 25$ (km s^{-1}) kpc^{-1} on the basis of the Schmidt model, and some support for such a value for Ω_p comes from the shape of the HI line profile in the direction of the anticentre[6].

Shu[7] has suggested an explanation for the absence of HII regions in the 600 pc–3 kpc region assuming that the inner Lindblad resonance occurs at about 3 kpc. Standard spiral density wave theory predicts that there should be no stellar density wave inside this radius, and therefore no shocks to produce the HII regions and so on. But although this could explain the deficiency of shock-generated species it does not explain why all the interstellar material is deficient there.

Here we propose an alternative explanation for the distribution of interstellar matter in the central region on the basis of a hypothetical stellar bar situated at the centre of the Galaxy. Sorensen, Matsuda and Fujimoto[8] have computed the flow of gas in barred spiral galaxies, assuming a specified potential due to the stellar bar plus a stellar disk, and neglecting the self gravity of the gas. The results of these calculations show that two pairs of shocks are formed. One pair are straight, almost radial shocks situated on the leading side of the bar (B in Fig. 1), and the other pair are trailing spiral shocks originating near the bar–gas corotation points (S in Fig. 1). The S shocks can be identified with the trailing spiral arms in barred galaxies, while the B shocks are sometimes observed as straight, bisymmetric dark lanes within the stellar bar[9].

The most important aspect of the B shocks as far as the present considerations are concerned is that they induce a strong inflow of gas, so that almost all the gas originally occupying the region within the corotation points is swept into a dense nucleus at the centre of the bar. The physical reason for this is that the gas plunges into the B shocks almost at normal incidence leading to a very strong shock (in contrast to the weaker shocks in ordinary spirals with oblique incidence). The gas loses both angular momentum and energy (by radiation), and consequently falls towards the centre after the shock, slowly spiralling inwards as it successively traverses the shocks. The gas flow through the S shocks is more complicated with infall produced in the inner part of the shock while outside the corotation point the gas gains angular momentum in passing through the shock density peak and spirals outwards, although much more slowly than the infall produced by the B shocks due to the higher obliquity of incidence. In this manner the stellar bar acts as a 'vacuum cleaner' sweeping gas

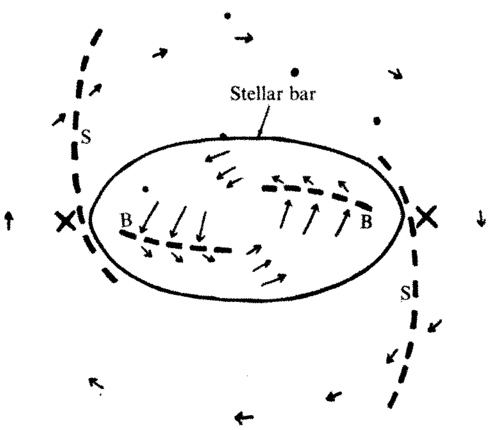

Fig. 1 Schematic diagram of the circulation of gas in a barred galaxy from the calculations of Sorensen, Matsuda and Fujimoto[8]. Arrows represent the velocity of the gas in direction and magnitude in the rest frame of the bar, the density peaks produced by the shocks are shown by the broken lines, and the crosses represent the bar–gas co-rotation points.

and dust away from the corotation region. Observations[10] of HI in barred spirals support this result in that a dense nucleus is observed at the centre of the bar along with an extended ring coincident with and extending beyond the optical spiral arms.

A small central bar at the centre of ordinarily spiral galaxies has been previously proposed in a few contexts. Mishurov and Suchkov[11] have suggested that spiral density waves may be excited by a rotating central bar, while Contopoulos[12] has shown from the calculation of stellar orbits that a gravitationally self-consistent bar can be obtained inside the inner Lindbald resonance. From the observational viewpoint attempts[13] have been made to explain the radial motions of HI at the galactic centre in terms of elliptic orbits which could possibly be induced by a bar. Observations of Cohen and Davies[14] are not inconsistent with this explanation of the radial motions, and furthermore the geometry of the HI features which they have obtained are highly suggestive of a stellar bar in that their features IIIa and XIVa would correspond to the B shocks, while features XII and I would correspond to the S shocks. If the steep drop in the interstellar densities at 2–4 kpc represents the outer extent of the in-sweeping effect of a bar then the corotation point of the gas with respect to the bar should occur at approximately this radius. This is in reasonable agreement with the extent of features IIIa and XIVa, which should lie within the corotation points, and in fact extend out to 2 kpc.

If the bar corotates with the spiral wave pattern in the outer part of the Galaxy at say 25 (km s^{-1}) kpc^{-1} then we would require a deep minimum in the rotational velocity of the gas somewhere in the region of 2 kpc from the centre in order to have a bar–gas corotation point there. This is inconsistent with the Rougoor–Oort rotation curve[15]; however the presence of strong radial motions in the central part of the Galaxy must make the definition and evaluation of the rotational velocity there uncertain, and the rotational velocities of some of the central features obtained by Cohen and Davies suggest at least the possibility of a deep minimum between 1 and 2 kpc. Such a rotational velocity minimum is observed in M31 (ref. 16), and it is noteworthy that a ring-like distribution plus a dense central nucleus for interstellar material in M31 is indicated by the combined HI and radio continuum observations.

On the other hand it is not obvious that the bar needs to co-rotate with the spiral pattern; the two may be dynamically independent with the bar rotating more rapidly than the spirals. A bar–gas co-rotation point could then be obtained at a radius of say 2 kpc even with the Rougoor–Oort rotation curve. For example, in the central part of NGC4314 tiny spirals appear which seem to be independent of the grand design[9].

In summary the presence of a small bar at the centre of our galaxy could provide a single explanation for three puzzling aspects of galactic structure, namely the strong central radial motions, HI features IIIa and XIVa, and the region between 600 pc and 2–4 kpc deficient in interstellar matter. We can estimate the mass of the bar under the assumption that it is the most massive constituent within the hypothetical bar–gas co-rotation point at approximately 2 kpc. This leads to a value less than a tenth that of the total galatic mass, which should be compared with the situation in normal barred spirals where the mass of the bar is probably a much more substantial fraction of the total mass.

Mass distribution of massive meteoroids determined by occurrence of brilliant fireballs

DETERMINATION of the mass distribution function of bodies is of prime importance for an understanding of the evolutionary processes that determine the population of the Solar System. We report here a method for measuring mass distribution of meteoroids, by determining the occurrence frequency of very brilliant fireballs. In a certain mass regime the number distribution can be described by a power law

$$dn = (\text{const.})m^{-s}\,dm$$

where dn is the number of particles having a mass between m and $m+dm$ and s is the mass distribution index. s is a slowly varying function of mass, and values of s have been well established for meteoroid particles $10^{-12} < m \lesssim 10^{1}$ g by various techniques, and reasonable estimates are available for large bodies $m \gtrsim 10^{5}$ g (meteorites and asteroids). There is, however, a lack of information in the mass range $10^{1} \lesssim m \lesssim 10^{5}$ g corresponding[1] to meteoroids which yield meteors of visual magnitude $-2 \gtrsim M_v \gtrsim -12$ ranging from bright visual objects to very brilliant fireballs (the term fireball generally refers to any meteor brighter than Venus, $M_v \simeq -4$). The problem is one of sampling: while meteor (radar, visual, optical) counts over periods of hours at a single station are suitable for estimates of s for $m \lesssim 1$ g ($M_v \gtrsim 0$), such a procedure yields a prohibitively low count for larger objects. This difficulty would be overcome by observing over a large area of the Earth's surface for many years. We determine here the occurrence frequency of very brilliant fireballs, as a method of s measurement. A fireball of magnitude equal to that of the full Moon is an outstanding spectacle likely to be well reported in an area with a high population density. With good communications and active research groups analysing reports and recording data, a reliable estimate of the influx of such large objects could be secured. In the British Isles, extensive records of fireball events covering more than 40 yr, are available[2,3]. Most observers' estimates were based on the great illumination produced on the landscape or inside buildings, and the personnel analysing the reports were experienced workers in the field. A detailed examination of the reports reveals a consistent rate of about two lunar fireballs (apparent visual magnitude equal to or brighter than that of the full Moon) seen in the British Isles per year. Specifically, in the period 1900–36 the average occurrence frequency was 2.4 yr^{-1}. This frequency can be compared with that of visual meteors to obtain an estimate of s.

Assuming that meteor luminosity is proportional to pre-entry meteoroid mass, m, the cumulative flux N of meteors having magnitudes equal to or less than absolute magnitude, M is given by

$$\log_{10}N = (\text{const.}) - ((s-1)/2.51)M$$

For a single observer the average rate of sporadic meteors $M_v \leqslant 0$ is 0.86 h^{-1} (ref. 1), and as s is known[4] to be close to 2.35 for $+4 \leqslant M_v \leqslant -2$, the cumulative rate for $M_v \leqslant -2$ is 7.34×10^{-2} h^{-1}. Estimating the surface area viewed from the British Isles as 4×10^5 km^2, then with an area of 1.16×10^5 km^2 under surveillance by a single observer[1], the average rate for the geographical area is 2.52×10^{-1} h^{-1}.

Of the lunar fireballs during the 36-yr period, 85% were observed between 1800 and 0200 UT, with 50% occurring 2000–2300 UT (reflecting an observation bias rather than any true variation). The effective observing period is close to 8 h d^{-1}; also for this period the visual sporadic rate is close to the diurnal mean value. Although clear skies are not necessary for the detection of such brilliant objects, detection conditions depend upon the prevailing cloud type. If a cloud cover of $<7/10$ is required for detection, however, the percentage time available in the British Isles is[5] about 40%. Hence the average lunar fireball occurrence frequency becomes 2.05×10^{-3} h^{-1}. As the height of maximum luminosity is lower for brighter meteors, the apparent magnitude $M_v \simeq -12$ of a lunar fireball needs correction. From the beginning and end heights of lunar fireballs, and noting that the maximum luminosity for bright objects occurs about three-quarters of the way along the trail[7], a mean height of 60 km is found. The absolute visual magnitude (referred to a standard height of 100 km) is therefore $M_v \simeq -11$. This implies that the observed fireballs are nine stellar magnitudes brighter than meteors of $M_v = -2$.

If meteors which differ in absolute magnitude by ΔM have occurrence frequencies of N_1 and N_2, then

$$s = 1 + (2.51/\Delta M)\log_{10}(N_1/N_2)$$

leading to $s = 1.58$. The reported mean annual lunar fireball rate of 2.4 showed no systematic variation over the 36-yr period, and it seems unlikely that this value would have an uncertainty exceeding 50%. With independent sightings of a large number of fireballs, systematic magnitude errors would not be expected, and it is not unreasonable to assign an uncertainty in ΔM of ± 1 mag. The estimate of the mass distribution index, s, is thus quite good: the uncertainty in N_2 leads to an error of 0.05 in s, and the uncertainty in ΔM implies an eror of 0.06. We conclude that $s = 1.58 \pm 0.08$. The observed fireball rate is incompatible with large values of s suggested by some authors: a value of $s = 2.34$ appropriate to visual meteors implies only one lunar fireball sighting in the British Isles every 200 yr.

Gravitational radiation from freely-falling bodies

THE problem of determining the gravitational radiation from freely-falling bodies is almost as old as general relativity itself. Investigators have deduced an energy loss, an energy gain and no radiation at all[1]. Although Eddington[2] foresaw the difficulties a half century ago, many now believe that the Einstein quadrupole formula correctly describes the rate of energy loss[3]. Cooperstock initiated a new approach to the problem by considering two bodies in an initially static configuration by virtue of an intervening strut[4]. The strut was severed and the dynamical perturbation to the gravitational field was analysed. During the stress-breaking period, the radiated energy loss agreed with the quadrupole formula. During free fall, however, the model with two point masses proved inadequate and an interior metric was required. Even then, there were indications of a breakdown of the quadrupole formula and a much larger energy flux. A model of realistic sources has now been constructed and the previous indications have been realised. The free-fall energy loss rate exceeds that which would be anticipated by the quadrupole formula by a factor of $(\alpha/\rho_0)^4$, where ρ_0 is the characteristic size of the bodies and 2α is their separation.

The model is chosen to consist of two perfect fluid spheres of radius ρ_0 with thin retaining skins. If the zero order density and pressure are

$$^{0}\varepsilon = \text{constant},\ ^{0}P = 0 \tag{1}$$

then the metric within the spheres and strut can be expressed in the form[5]

$$\mathrm{d}s^2 = \mathrm{e}^{2\nu}\mathrm{d}t^2 - \mathrm{e}^{2(\gamma-\nu)}(\mathrm{d}r^2 + \mathrm{d}z^2) - r^2\mathrm{e}^{2(\mu-\nu)}\mathrm{d}\varphi^2 \tag{2}$$

where μ is of order G^2. From the Einstein field equations, it follows that ν and γ are of the order G and G^2, respectively, in the sources, as they are in vacuum. The field equations imply that ν satisfies the Poisson equation

$$\nabla^2\nu = 4\pi G T_4^{\ 4} \tag{3}$$

From equations (1) and (3) and the conservation laws

$$\mathrm{T}^{ik};k = 0 \tag{4}$$

the first order static pressure is found.

In a short time interval, counterstresses are applied to remove the supporting strut and envelopes, and free fall begins. The metric is then described as a second and third order perturbation of the background metric (equation (2)). The second order dynamic metric is found to have the required continuity and to be singularity-free only when the complementary phenomena of stress-breaking in the strut, pressure variation in the bodies and the ensuing free-fall motion are properly synthesised. Using the field equations, it is possible to express one of the elements b' of the third order pertubation in an inhomogeneous wave equation with the first and second order fields and the dynamic energy–momentum tensor T^{ik} as sources. This lengthy equation may be expressed symbolically in the form

$$\Box\, b' = (\mathrm{T}) + (\nu)(b) \tag{5}$$

where (T) represents terms which are linear in components of the energy–momentum tensor and $(\nu)(b)$ represents the nonlinear terms which are functions of products of the first-order background metric and the second-order dynamic perturbation.

It was shown[4] that the source terms above which neglect nonlinearities, yield precisely the energy flux of the quadrupole formula. For free fall, attention must also be focused on the remaining nonlinear contributions to b'. The analysis of the contributions from the many source terms is very lengthy and difficult and will be fully delineated in another publication[6]. As anticipated[4], certain parts of the source for b' combine to give the dominant asymptotic contribution

$$b' = -4\frac{G^3m^3}{\alpha^2\rho_0^2}\quad\frac{(t-\rho)^2}{\rho}$$

where ρ is the radial coordinate. This yields a gravitational energy flux

$$\frac{\mathrm{d}E}{\mathrm{d}t} = -16\frac{G^5m^6}{\alpha^4\rho_0^4}(t-\rho)^2$$

during the early stages of free fall.

Unlike electrodynamics, the radiated energy is dependent upon the structure of the sources. This is not surprising because of the important role of nonlinearities which are absent in electrodynamics. Indeed, it was shown[4] that the linear terms alone imply a structure-independent radiation.

For a given separation and mass, the flux increases with diminishing size ρ_0. This is understandable because of the increased background field intensity, which contributes through the nonlinearities to the radiation. It is to be emphasised that the expression for the flux loses its validity if ρ_0 is allowed to become so small as to violate the weak-field condition.

The harmonic coordinate condition, which has caused others difficulty for asymptotic calculations, has not been employed. Moreover, the problem of avoiding the intrusion of incoming radiation is solved by the development from an initially static configuration.

The usual derivation of the quadrupole formula treats the retarded integrals as for compact sources in electrodynamics. Moreover, various surface integrals containing the energy–momentum pseudotensor are discarded on application of the Gauss theorem. These procedures are justified both in electrodynamics for compact sources and in general relativity when the compact sources dominate the field sources. During free fall, however, the field sources are of the same order as the compact sources and the analysis leading to the quadrupole formula is inapplicable.

Stable photoelectrochemical cells for the splitting of water

FOLLOWING Fujishima and Honda's suggestion of water photolysis by a photoelectrochemical cell[1], no stable cell has been reported (but compare refs 2, 3) capable of water decomposition without the application of either an external bias or a pH gradient. The main problems have been to find stable anodes and cathodes with sufficiently negative and positive critical photopotentials, respectively, so that they may be suitably combined in a self-driving photo cell producing hydrogen and oxygen from water. We report here that the anodes n-TiO_2 and n-$SrTiO_3$ and the cathodes p-CdTe and p-GaP can be combined to form four separate stable self-driven cells: n-TiO_2–p-CdTe, n-TiO_2–p-GaP, n-$SrTiO_3$–p-CdTe and n-$SrTiO_3$–p-GaP capable of water photoelectrolysis.

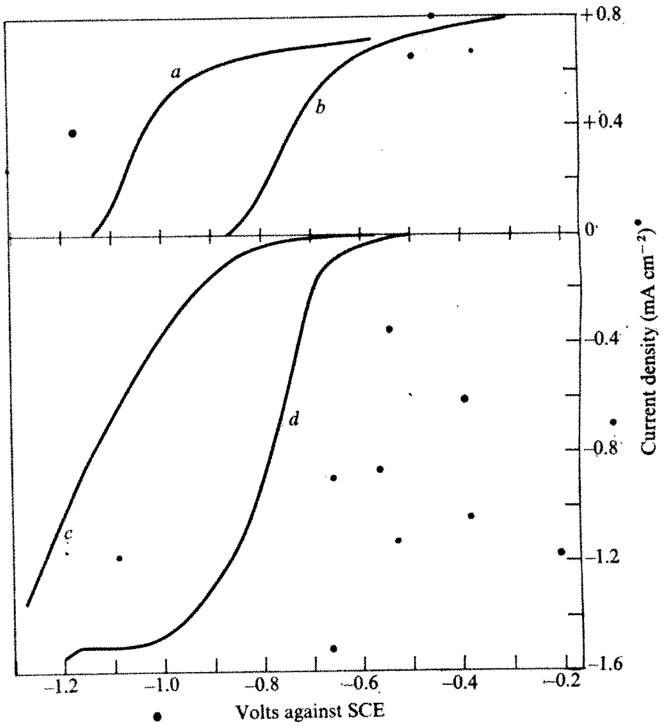

Fig. 1 Photocurrent–potential curves of semiconductor electrodes against Pt in 1 M NaOH, 25 °C. *a*, n-$SrTiO_3$; *b*, n-TiO_2; *c*, p-CdTe; *d*, p-GaP. Potential sweep rate: 10 mV s^{-1}. Areas: n-TiO_2, p-CdTe and p-GaP, 0.0491 cm^2, n-$SrTiO_3$, 0.0594 cm^2, 0.05 W cm^{-2}.

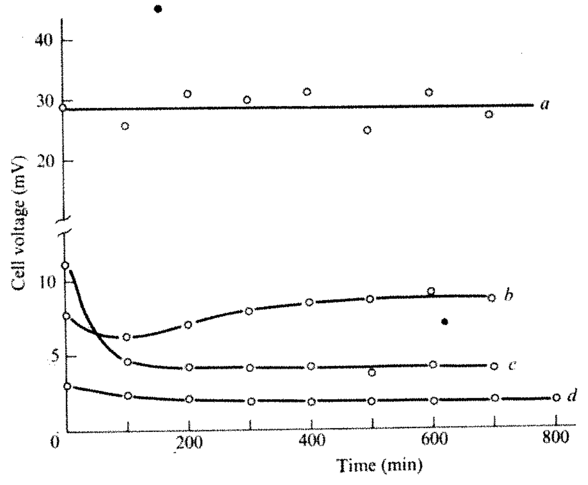
TiO_2 (001 face) and $SrTiO_3$ polished single crystals were reduced in H_2 at 800 and 900 °C for 5 and 3 h, respectively, to form low-resistance n-type crystals. Ohmic contacts to both

Fig. 2 Cell voltage–time curves of self-driven electrochemical hydrogen producers. *a*, $SrTiO_3$–GaP; *b*, $SrTiO_3$–CdTe; *c*, TiO_2–GaP; *d*, TiO_2–CdTe. External resistance 1 kΩ. Areas: n-TiO_2, p-CdTe and p-GaP, 0.0491 cm^2, n-$SrTiO_3$, 0.0594 cm^2 in 1 M NaOH, light intensity 0.05 W cm^{-2}, 25 °C.



crystals were obtained by soldering indium on to the crystals. An ohmic contact to a p-CdTe (undoped; 110 face) was formed by depositing gold on a silver diffused layer. An ohmic contact to p-GaP (Zn doped; 100 face) was formed by soldering an In–Zn alloy on to the back of the crystal. The crystals were positioned in Teflon holders and fixed with epoxy resin.

Each pair of electrodes was positioned in adjacent compartments of an electrochemical cell with a water jacket. The light from a 900-W xenon lamp was split equally with front surface mirrors of evaporated aluminium film on glass plates and used to irradiate each electrode.

The photocurrent–potential curves of the four electrodes in 1 M NaOH, light intensity 0.05 W cm^{-2} at 25 °C are shown in Fig. 1. The two n-type electrodes n-TiO_2 and n-$SrTiO_3$ can be combined with both p-CdTe and p-GaP to form self-driving photoelectrolysis cells.

The stabilities of the cells were determined by measuring the cell voltage as a function of time with an external resistance of 1 kΩ (Fig. 2). The cell voltage in each case after reaching a steady-state value after some 3 h was still stable after 12 h, although there were some fluctuations due to instability in the light source. Some electrodes were used satisfactorily for a total of 50 h in various cells.

The chemical output power of each cell (Fig. 3) was calculated from the maximum cathodic current densities based on the free energy change of $H_{2(g)}$ to $H_2O_{(l)}$, that is, 1.23 (V) × i, where i is the cathodic current density.

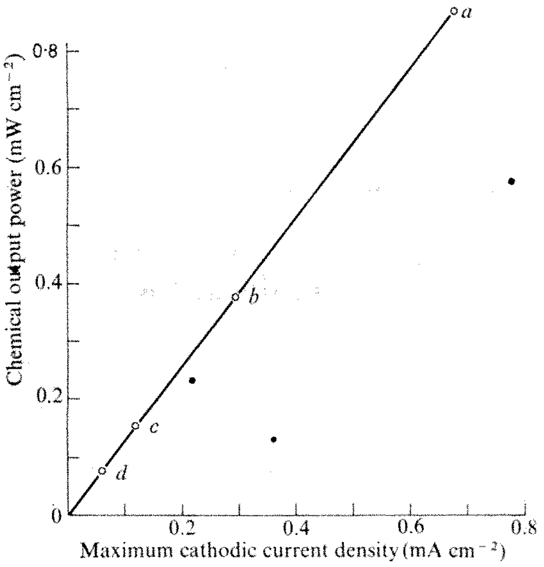


Fig. 3 Maximum cathodic current densities of self-driven electrochemical hydrogen producers and their chemical output power densities based on the free energy change of $H_{2(g)}$ to $H_2O_{(l)}$, that is expressed as 1.23(V) × i, where i is the current density. a, $SrTiO_3$–GaP; b, $SrTiO_3$–CdTe; c, TiO_2–GaP; d, TiO_2–CdTe. Areas: n-TiO_2, p-CdTe and p-GaP, 0.0491 cm^2, n-$SrTiO_3$, 0.0594 cm^2. 1 M NaOH, light intensity 0.05 W cm^{-2}, 25 °C.

The efficiencies of the cells in xenon light were calculated and are listed in Table 1. The efficiencies are still too low to be of practical applicability, but the difficulty is caused by the large energy gaps of the photo-anodes n-TiO_2 (3.0 eV) and n-$SrTiO_3$ (3.8 eV). From the energy gaps of p-GaP (2.25 eV) and p-CdTe (1.5 eV), it is possible to estimate that these electrodes can use up to 2 and 13% of the solar spectrum, respectively.

Thus, the major problem if this method is to be considered as a contender for a method of H_2 production is to find a stable anode (E_G 1.0–1.8 eV) with a critical photopotential such that it can be efficiently combined with p-CdTe in a self-driving hydrogen producer. The present results do not preclude the development of cells with an efficiency of > 7%.

Table 1 Efficiencies of cells in xenon light*

Cell†	Efficiency in xenon light (%)
n-TiO_2–p–CdTe	0.044
n-TiO_2–p-GaP	0.098
n-$SrTiO_3$–p-CdTe	0.18
n-$SrTiO_3$–p-GaP	0.67

*Conditions: 1 M NaOH, 25 °C, light intensity, 0.05 W cm^{-2}.
†Electrode areas: n-TiO_2, p-CdTe, p-GaP, 0.0491 cm^2; n-$SrTiO_3$, 0.0594 cm^2.

We thank M. H. Kimura for the CdTe single crystals, Dr K. Akita for the GaP single crystal and Dr D. I. Tchernev for the $SrTiO_3$ single crystal.

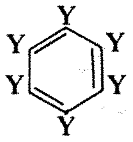
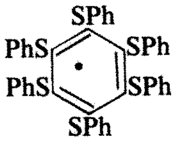
Crystal and molecular structure of a 'hexa-host' inclusion compound

WE recently suggested[1], and found experimental support for[1,2], a totally new concept for the design of inclusion compounds. Using this design concept we prepared a series of host compounds based on a hexa-substituted benzene ring (I), and we now report the results of the first X-ray structural study on one of these compounds.



(I)



(II)

The carbon tetrachloride adduct of hexa-phenylthiobenzene (II) is trigonal with a unit cell (a=14.263; c=20.717 Å) containing three molecules of $C_{42}H_{30}S_6$. A host–guest (carbon tetrachloride) ratio of 1:2 was found by microanalysis for chlorine. The space group is either R3 or R$\bar{3}$ (ref. 3), the centrosymmetric space group (R$\bar{3}$) was chosen and this choice has been justified by the success of the subsequent analysis. The structure was solved by direct methods using 2071 independent reflections measured with Mo–Kα radiation on a Hilger–Watts automatic diffractometer (using a Lindemann capillary for crystal containment), and refined to a final R value of 0.055. All the hydrogen atoms have been located and allowed for, as have the guest molecules. Full details of the structural analysis will be published elsewhere.

Figure 1 shows a general view of the host molecule. It is centred on a point of $\bar{3}$ symmetry; thus the crystallographically equivalent 'legs' of the molecule point alternately above and

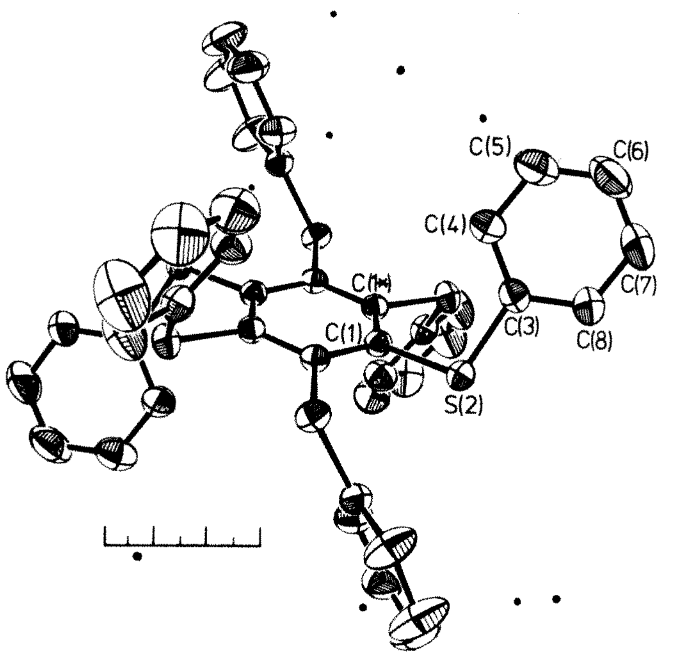


Fig. 1 An ORTEP drawing showing a general view of the molecular structure of host molecule (II) in the crystal of the CCl_4 clathrate. (The hydrogen atoms are not shown). Bar represents 3 Å.

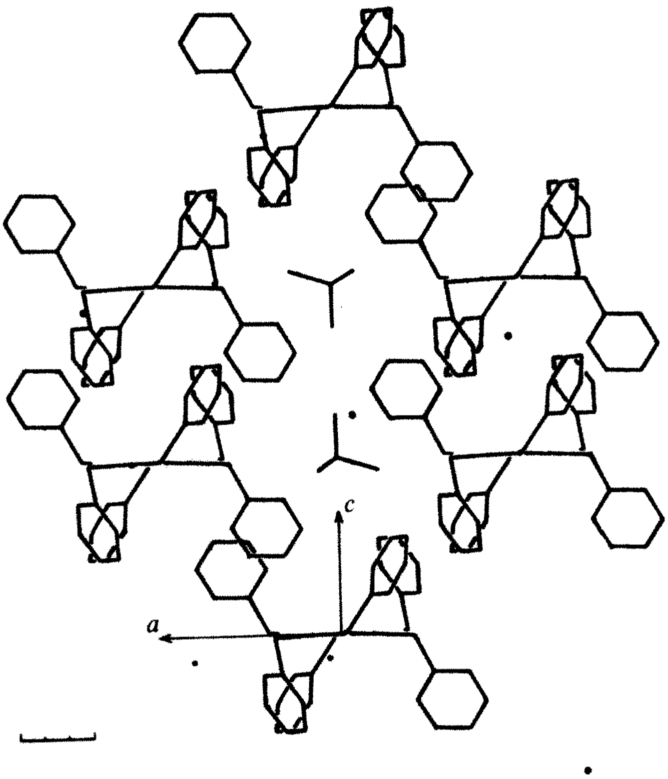
below the plane of the central benzene ring. The relative orientation of the central and side-chain aromatic rings may be appreciated by a consideration of the torsion angles C(1*)–C(1)–S(2)–C(3) and C(1)–S(2)–C(3)–C(4), which are 56° and 28° respectively.

Figure 2 illustrates the host–guest packing arrangement in the crystal; the two host molecules which complete the cage (which lie above and below the cavity as reviewed in the direction shown) have been omitted for clarity. The two CCl_4 guest molecules in the clathrate cage are orientated such that a C–Cl bond of each is co-linear with the *c* axis. Although relatively small gaps have been detected in the cage wall these are insufficiently large to allow the guest molecules to escape unhindered. Solvent loss does in fact occur slowly when the crystals are left in air at room temperature, with apparent complete disruption of the crystal lattice.

Fig. 2 An illustration of the host–guest packing in the crystal of the CCl_4 clathrate of (II), as viewed on to the *ac* plane. Two host molecules which lie above and below the cavity as viewed in this direction have been excluded to show the guest molecules more clearly. Bar represents 3 Å.



The crystal packing forces seem to be of the normal van der Waals' type, no evidence having been found to suggest marked charge transfer interactions between host and guest molecules.

A host–guest ratio of 1:2 has also been found for the guests CCl_3CH_3 and CCl_3SCl, though guest species CCl_3Br and CCl_3NO_2 form complexes with a 1:1 ratio. Recrystallisation of (II) from the solvent CCl_3CCl_2H gives unsolvated triclinic crystals.

Further studies on other 'hexa-host' molecules indicate that trigonal symmetry is not always encountered in the inclusion compounds formed. A study of the complex of hexakis (benzylthiomethyl) benzene (formula (I), Y=CH_2SCH_2Ph) with dioxane has shown the crystals to be monoclinic, space group $P2_1/c$, with two host and two guest molecules in the unit cell.

We thank the SRC for financial support.

Effect of magnetic field on reduction of iron oxides: magnetite and wüstite

A STRONG magnetic field (500–1,400 Oe) was reported by Skorski[1] to cause an increase in the reduction rate of haematite (Fe_2O_3) to metallic iron when H_2 was used as the reducing agent. This effect was attributed to the magnetic properties of the H_2, because neither CH_4 nor CO produced a similar increase when under the influence of a strong magnetic field. Although Svare[2] disputed this explanation, Peters[3] offered an alternative one, based on thermodynamics, which indicated that an increase in reaction rate is expected under the influence of a strong magnetic field when the reactants were relatively non-magnetic and the products were strongly magnetic—as with reduction of haematite to iron. We report here our results of studying magnetite and wüstite reduction to iron, which show an increased reduction rate for magnetite, under the influence of a strong magnetic field, but an inexplicably decreased rate for the wüstite reduction.

Confirmation of the effect noted by Skorski[1] was attempted by Rowe *et al.*[4]. To avoid the complication arising from the two-step process of haematite to iron reduction with H_2 below 550 °C ($Fe_2O_3 \rightarrow Fe_3O_4 \rightarrow Fe$), Rowe *et al.* examined the simpler nickel oxide–nickel system. The NiO → Ni reduction meets Peters' criterion for expected reduction rate effects from applied magnetic fields almost as well as the $Fe_2O_3 \rightarrow Fe_3O_4 \rightarrow Fe$ system does. That is, NiO is relatively non-magnetic (paramagnetic) whereas Ni is ferromagnetic (saturation magnetisation $\simeq$ 54). Fe_2O_3 is relatively non-magnetic (antiferromagnetic), while metallic Fe is also ferromagnetic (saturation magnetisation $\simeq$ 218). (Fe_3O_4 is also relatively magnetic, being ferromagnetic with saturation magnetisation $\simeq$ 92.) Rowe *et al.* found that application of a strong magnetic field (~4,200 Oe) produced no detectable difference in the reduction rate of NiO to metallic Ni and therefore failed to confirm the general effect expected in the reduction of a non-magnetic species to a magnetic one.

Having observed no difference in reduction rate of NiO to Ni on the application of a strong magnetic field, we now check more directly Skorski's observation on Fe_2O_3 reduction. At temperatures less than 550 °C, Fe_3O_4 is formed as an intermediate; Skorski did not attempt to account for this effect. To eliminate this complication, we decided to investigate here the reduction of magnetite and wüstite (FeO) to metallic iron. According to Peters' thermodynamic argument, the rate of reduction of FeO to Fe should be enhanced to a greater degree than expected for Fe_3O_4 to Fe, since magnetite is more strongly magnetic than wüstite. That is, the change in saturation magnetisation is greater in reducing FeO to Fe than in reducing Fe_3O_4 to Fe. Also, both of these reaction rates should be enhanced to a greater extent than in the NiO → Ni case, if Peters is correct.

Our apparatus[4], which allows continuous observation throughout the reduction (an advantage over Skorski's 'observation after the fact' method), consists of an electrobalance (sensitive to 10^{-6} g) connected to a strip chart recorder to trace the weight of reactant (Fe_3O_4 or FeO) plus product (Fe). When the strong magnetic field is applied, the apparent weight (saturation magnetisation) of the Fe_3O_4 and Fe or the FeO and Fe are recorded. The temperature was measured by means of a thermocouple inserted nearby the quartz sample pan.

Before each run, the electrobalance system (including sample) was flushed at room temperature with 20% H_2 in N_2 carrier at a rate of 65 ml min^{-1} for at least 1 h to assure a constant reaction atmosphere for each run. The gas flow was continued until the reaction was essentially 100% complete and the experiment was ended. We used ~1–3-mg samples of powdered Fe_3O_4 and FeO. The Fe_3O_4 samples were powdered to 200 mesh; finely powdered FeO samples were used but the mesh was not known. All experiments were begun at room temperature (~24 °C) and reached ~385 °C (for magnetite) after about 8 min, ~490 °C (for wüstite) after about 10 min. Reaction did not occur until near the reaction temperature.

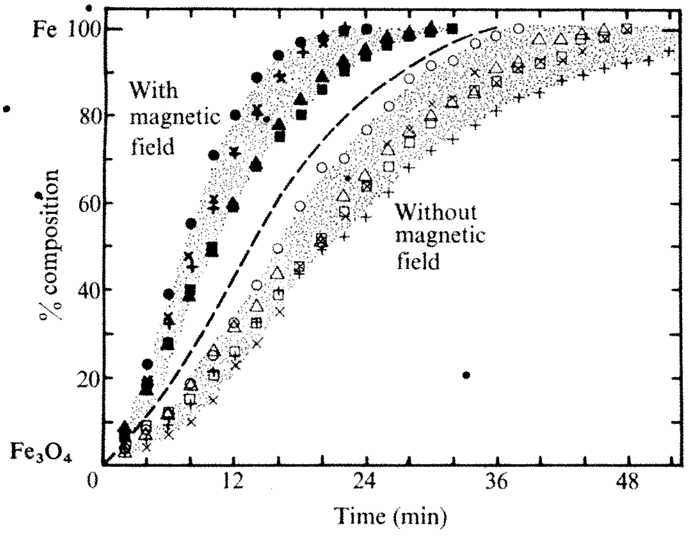

Fig. 1 Reduction of Fe_3O_4 to metallic iron with a 65-ml-min^{-1} flow of 20% H_2 in N_2 carrier at ~385 °C. Points were hand-read from a strip chart recording for construction of Fig. 1 so that data taken under the influence of a strong magnetic field can be directly compared with those without the strong magnetic field. The mass data were recorded continuously. Data on the left side of the dashed line in Fig. 1 were recorded after the insertion of an ~4,200-Oe permanent magnet. Initial sample weights (Fe_3O_4): ●, 0.98 mg; +, 0.98 mg; ▲, 1.29 mg; ■, 2.27 mg; ×, 1.42 mg. Data on the right side of the dashed line in Fig. 1 were recorded in the Earth's magnetic field (~0.5 Oe). Initial sample weights (Fe_3O_4): ○, 1.24 mg; +, 1.53 mg; △, 2.22 mg; □, 1.54 mg; ×, 1.18 mg.

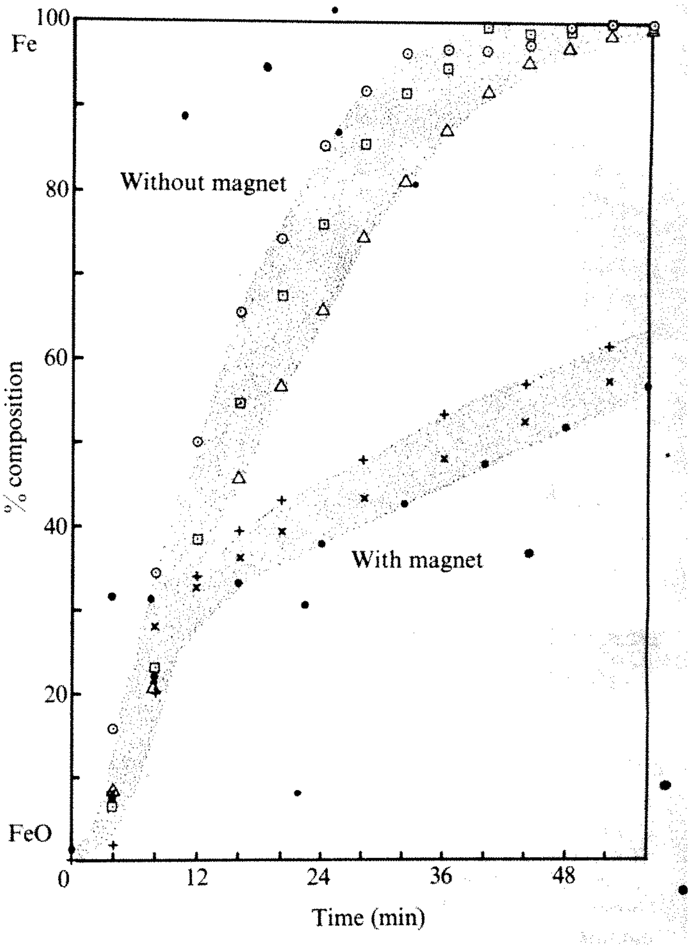

Fig. 2 Reduction of wüstite to metallic iron with a 65-ml min^{-1} flow of 20% H_2 in N_2 carrier at ~490 °C. Points were hand-read from a strip chart recording (see Fig. 1 legend). The mass data were recorded continuously. Data on the left side of Fig. 2 were recorded in the Earth's magnetic field (~0.5 Oe) those on the right side were recorded after the insertion of an ~4,200-Oe permanent magnet. Initial sample weights (FeO): ○, 1.31 mg; □, 1.76 mg; △, 2.51 mg; ●, 2.46 mg; +, 1.05 mg; ×, 2.25 mg.

For magnetite, five runs were performed in the Earth's field, and five after the insertion of an ~4,200-Oe permanent magnet (Fig. 1). The reductions were all carried to essential completion (as confirmed by stoichiometry), and the reduction rates compared. Skorski's[1] reductions were not generally carried to completion. Figure 1 shows that the reduction of magnetite to iron occurred at a significantly faster rate under the influence of the strong magnetic field, thus confirming Skorski's observation by an independent technique. This is not, however, direct confirmation because we found the reaction rate was increased on reducing Fe_3O_4 to Fe, whereas Skorski started with Fe_2O_3 and ended with an Fe_2O_3, Fe_3O_4 and Fe mixture of unknown composition.

For the wüstite reduction, three runs were conducted with a strong magnet, and three without (Fig. 2). The reductions were all carried to (and recorded to) essential completion, as for magnetite, and the rates compared. Although the data for the wüstite reduction in the presence of the strong magnetic field are not shown to completion in Fig. 2, the difference in rates brought about by the magnetic field is apparent.

Surprisingly, we found that the application of a strong magnetic field during the wüstite reduction with H_2 resulted in a significantly slower reaction rate than when the reduction was conducted in the Earth's field. This supports our earlier suspicion that Peters's[3] thermodynamic argument was not the determining factor in the reductions studied to date (refs 1, 4 and present work). In all cases, the general requirement is met that the product be more highly magnetic than the reactant, but a strong magnetic field affects the reduction rates as follows:

$NiO \rightarrow Ni$	no observable effect
$Fe_2O_3 \rightarrow Fe_3O_4 \rightarrow Fe$ $Fe_3O_4 \rightarrow Fe$	reduction is speeded up
$FeO \rightarrow Fe$	reduction is slowed down

We are not able to explain these data at present. This work was supported by NASA.

Computer simulation and statistical geometric model for contacts in binary random two-dimensional disk packings

Experimental investigation of the characteristics of multicomponent packings of particles would involve a large number of manipulations for even very few components in the mixture, and each additional component would increase this number enormously. A method of calculating the properties of such mixtures would be of interest if only as a framework within which to design experiments. One difficulty is that for this very reason a theoretical approach cannot be subjected to a thorough experimental verification. We therefore think it useful to take the problem further by comparing two previously published theoretical approaches, by a statistical geometric model[1] and a computer simulation[2], for calculating the contacts between disks in two-dimensional multicomponent random mixtures.

The average total coordination number in a packing is defined as the total number of contacts in the packing divided by the total number of disks in the packing (C). In multicomponent packings this may be further subdivided: first, into the individual average coordination number for each disk size (c_i), that is, the total number of contacts on disks of a given size divided by the number of disks of that size; second, into the average coordination number for each size by each of the other disk sizes in the packing (p_{ij}).

In a binary packing, these various coordination numbers are related by the following expressions:

$$C = (n_1c_1+n_2c_2)/(n_1+n_2) \tag{1}$$

$$c_1 = p_{11}+p_{12} \tag{2a}$$

$$c_2 = p_{21}+p_{22} \tag{2b}$$

Note that $p_{12} \neq p_{21}$ but $n_1p_{12} = n_2p_{21}$

It was shown previously[1] that the average coordination number on each disk size (c_i) could be calculated from a disk size distribution (relative numbers of disks n_i and their diameters d_i) using a simple statistical geometric model of an idealised gapless packing of which the space was divided up into triangular subunits. The matrix of (p_{ij}) values can also be calculated from the model through the relative numbers of triangular subunits (T_{ijk}) calculated by expressions (3) and (4) in ref. 1. Each of these subunits includes three contacts and the relative numbers of the different types of contact between disks can therefore be calculated. For a binary mixture there are three types of contact and expressing these as fractions of the total number of contacts we have

$$t_{11} = (T_{111}\times 3+T_{112})/3 \tag{3a}$$

$$t_{22} = (T_{222}\times 3+T_{122})/3 \tag{3b}$$

$$t_{12} = t_{21} = (T_{112}\times 2+T_{122}\times 2)/3 \tag{3c}$$

$$t_{11}+t_{22}+t_{21} = 1 \tag{4}$$

By definition and for a binary mixture

t_{11} = number of type 11 contacts/total number of contacts

$$t_{11} = (n_1\,p_{11})/(n_1c_1+n_2c_2) \tag{5a}$$

$$t_{22} = (n_2\,p_{22})/(n_1c_1+n_2c_2) \tag{5b}$$

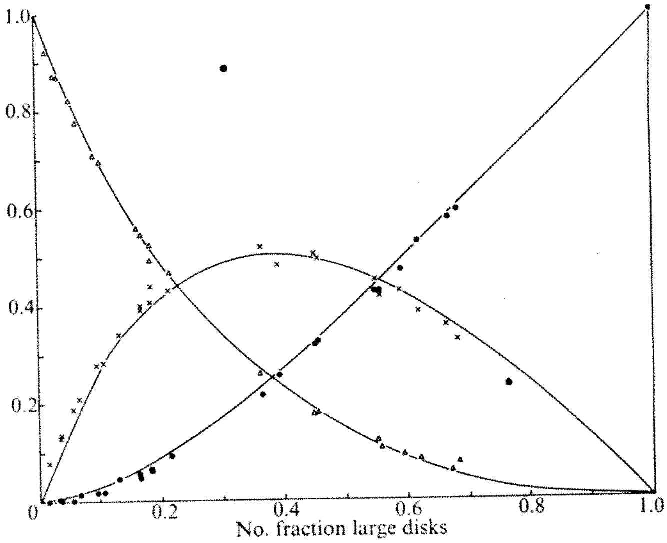
$$t_{21} = t_{12} = (n_1p_{12}+n_2p_{21})/(n_1c_1+n_2c_2) \tag{5c}$$

By elimination between expressions (2), (3) and (5) we may calculate values of p_{ij}.

As reported in ref. 2, the process simulated is that of disks being put into a two-dimensional box in random order from a random point and allowed to fall and roll until they attain a dynamically stable position. No adhesion or rebound is considered and once in position a disk is assumed not to move. The various coordination numbers are obtained by counting after rejection of the disks at the edge.

It is well known[3] that the porosity and coordination number in packings depend not only on geometrical factors (size distribution) but also on what may be called mechanical factors such as the conditions in which the packing is formed: vibrated, settled in water dropped from a height, or the properties of the grains other than size; their density, surface roughness, existence of attractive or repulsive forces. For example, a packing of monosize glass spheres can have a porosity of 0.40 or 0.36 and an average coordination number of 8 or 9 depending on whether the packing is vibrated or not. Grains with a higher density or with attractive forces between them tend to pack to lower porosities than grains with surface roughness or repulsive forces between them. As an example of these effects it is possible to simulate a looser packing with a lower total coordination number by including an adhesional probability in the computer simulation. When a disk is put into the box and touches another disk a random number is compared with the assumed adhesional probability: if the random number is smaller than the adhesional probability the disk is fixed in that position, if it is greater the disk continues to roll until the next contact when the procedure is repeated or the disk reaches a stable position. All the results reported here are

Fig. 1 Comparison of coordination points from the model with computer simulation. Diameter ratio 2.5. Values of t_{ij} are shown as curves, and computer simulation results are shown as points: △, t_{11}; ×, t_{12}; ●, t_{22}.



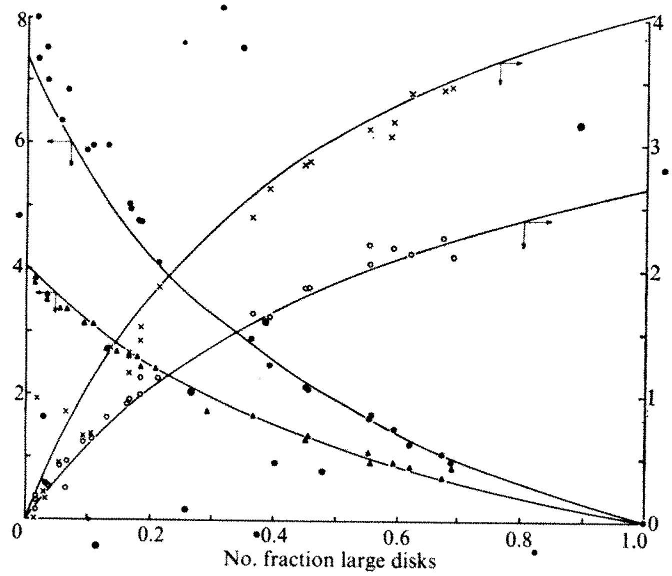


Fig. 2 Comparison of coordination points from the model with the computer simulation. Diameter ratio 2.5. Values of $_{ij}$ from the model multiplied by the compaction factor are shown as curves, and computer simulation results are shown as points: ▲, p_{11}; ○, p_{12}; ●, p_{21}; ×, p_{22}.

for an adhesional probability of 0%. Here the model is concerned only with geometrical factors and relates to an idealised compact gapless packing, with an average total coordination number of 6. The computer simulation includes mechanical factors to a certain extent and gives values for a more realistic packing with a constant average total coordination number of 4.02±0.04 for all mixtures considered here. This geometrical invariant may be used to define a 'compaction factor' which represents the degree to which mechanical factors allow real packings (here computer simulated) to approach the geometry of the idealised packing. In this case the factor is 4.02/6.00 = 0.67. Multiplying by this factor allows the different coordination numbers obtained from the model to be compared with the computer simulation. The figures show this comparison. Figure 1 (analogous to Fig. 3 in ref. 1) shows values of t_{ij} from the model as smooth curves and results from the computer simulation as points; the agreement is excellent. Figure 2 (analogous to Fig. 6 in ref. 2) gives values of p_{ij} from the model multiplied by the compaction factor as smooth curves and the results from the computer simulation as points. The agreement is excellent which indicates the concept of the compaction factor.

The comparison between the coordination numbers for two-dimensional binary random disk packings as calculated by computer simulation and a theoretical model shows a good agreement between the two methods. Notably the invariability of the average total coordination number with size ratios and mixture proportions is confirmed. This allows the definition of a 'compaction factor' which allows the results of the theoretical model for an idealised gapless packing to be used to calculate coordination numbers for real packings.

Gravity in Zambia

A RECONNAISSANCE gravity survey of the Republic of Zambia was carried out from 1971 to 1975 by the Geological Survey of Zambia in collaboration with the University of Zambia and The University of Michigan[1]. We present here a Bouguer anomaly map and preliminary analysis of the gravity data, in the context of the principal tectonic elements and structural characteristics of eastern and southern Africa.

Zambia is situated on the Central African Plateau which slopes gently from an elevation of 1,000 m in the south and west of Zambia to a maximum elevation of >2,000 m in the northeast. The characteristic gently sloping terrain is broken in the extreme north by the Tanganyika and Mweru rifts and in the east and south, respectively, by the Luangwa and mid-Zambezi rifts, which contain Karroo (Permo-Triassic) sediments and volcanic rocks. The plateau comprises principally Pan-African (450–750 Myr) and older igneous and metamorphic basement rocks. In the west, the basement is in places broken by fault block basins, but the distribution of these is obscured by a blanket of Quaternary Kalahari sands.

Over 2,700 gravity stations were established along the primary and secondary road network of Zambia, at approximately 10–15-km intervals, with a characteristic density of one station per 400 km². All stations were referenced to the previously established East African primary net[2]. Free-air and simple Bouguer anomalies were calculated using the 1930 International Gravity Formula and a density of 2.67 g cm⁻³. Elevations for about one-third of the stations were taken from topographic map contours; at the remaining stations, elevations were determined with aneroid barometers. A mean uncertainty of ±2 mgal, arising principally from uncertainties in elevation, is typical.

Our Bouguer anomaly map of Zambia (Fig. 1) shows Bouguer anomalies ranging between −200 and −75 mgal, with a mean near −140 mgal. The regions in the north and northwest marked by the −160-mgal contour lie along the axis of the so-called Great Negative Bouguer Gravity Anomaly[3] of Africa; the long and continuous −120-mgal contour in the south marks its approximate southern boundary. The overall grain of the map is dominantly northeast–southwest, a tectonic trend which is prominently displayed by the Upemba graben in southern Zaire, the Mweru and Luangwa rifts, the middle Zambezi valley, and which continues to the south-west into northern Botswana[4].

Some of the individual features of the map can be clearly identified with structural elements, the best example being the elongated gravity trough in eastern Zambia which coincides closely with the Luangwa rift. The southern terminus of the Tanganyika rift, and the northern margin of the Zambezi rift along Lake Kariba also show gravity depressions. The arcuate trend of the −140-mgal contour in the northern part of central and western Zambia follows closely the curvature of the Lufilian arc, a Pan-African age structural element that hosts the rich copper mineralisation of Zambia and southern Zaire. The moderate gravity depression in central western Zambia is associated with a zone of persistent seismic activity[5]; the large nearly circular depression in northern Zambia lies within a region of Precambrian platform sediments, and could represent a small sedimentary basin.

Three regions show prominent gravity highs: the eastern border with Malawi, the region south of Lake Mweru, and the region north of Lake Kariba. In each of these areas the anomalies reach −80 mgal with gravity relief of at least 40 mgal. These highs are not associated with any obvious structural elements or topographic settings; they are in areas with elevations of 900–1,800 m.

Residual anomalies were obtained by subtracting a smooth regional anomaly field from the observed Bouguer anomaly field. The regional pattern was estimated by a number of techniques, including free-hand smoothing, Fourier and polynomial surface-fitting methods, and a mean anomaly against elevation parameterisation. Each representation of the regional field yielded different residuals, but some anomalous regions were common to all of the residual fields. Those regions, each with residual anomalies >20 mgal (inset map of Fig. 1) display a north-east–south-west grain, as does the anomaly map. The most prominent feature is the chain of positive residuals extending from south-western Zambia north-eastward along the southern margin of the country. This remarkable feature merely traverses Zambia; it can be traced south-westward through Botswana to the Namibia border[4], and continues north-eastward into the Malawi highlands[6], approaching 2,000 km in length. This prominent positive residual buttresses the southern margin of the Great Negative Anomaly throughout central Africa.

The negative residual over the Luangwa rift arises from the low-density Karroo sedimentary fill. A similar residual probably exists in the mid-Zambezi valley beneath Lake Kariba, but it has not been confirmed due to a lack of data from the valley and beyond in Rhodesia. The negative residual which extends from the north across the Zaire pedicle into the Zambian Copperbelt possibly reflects relatively thick sedimentary accumulations in the north, but is associated with the Copperbelt granites at its south-western terminus.

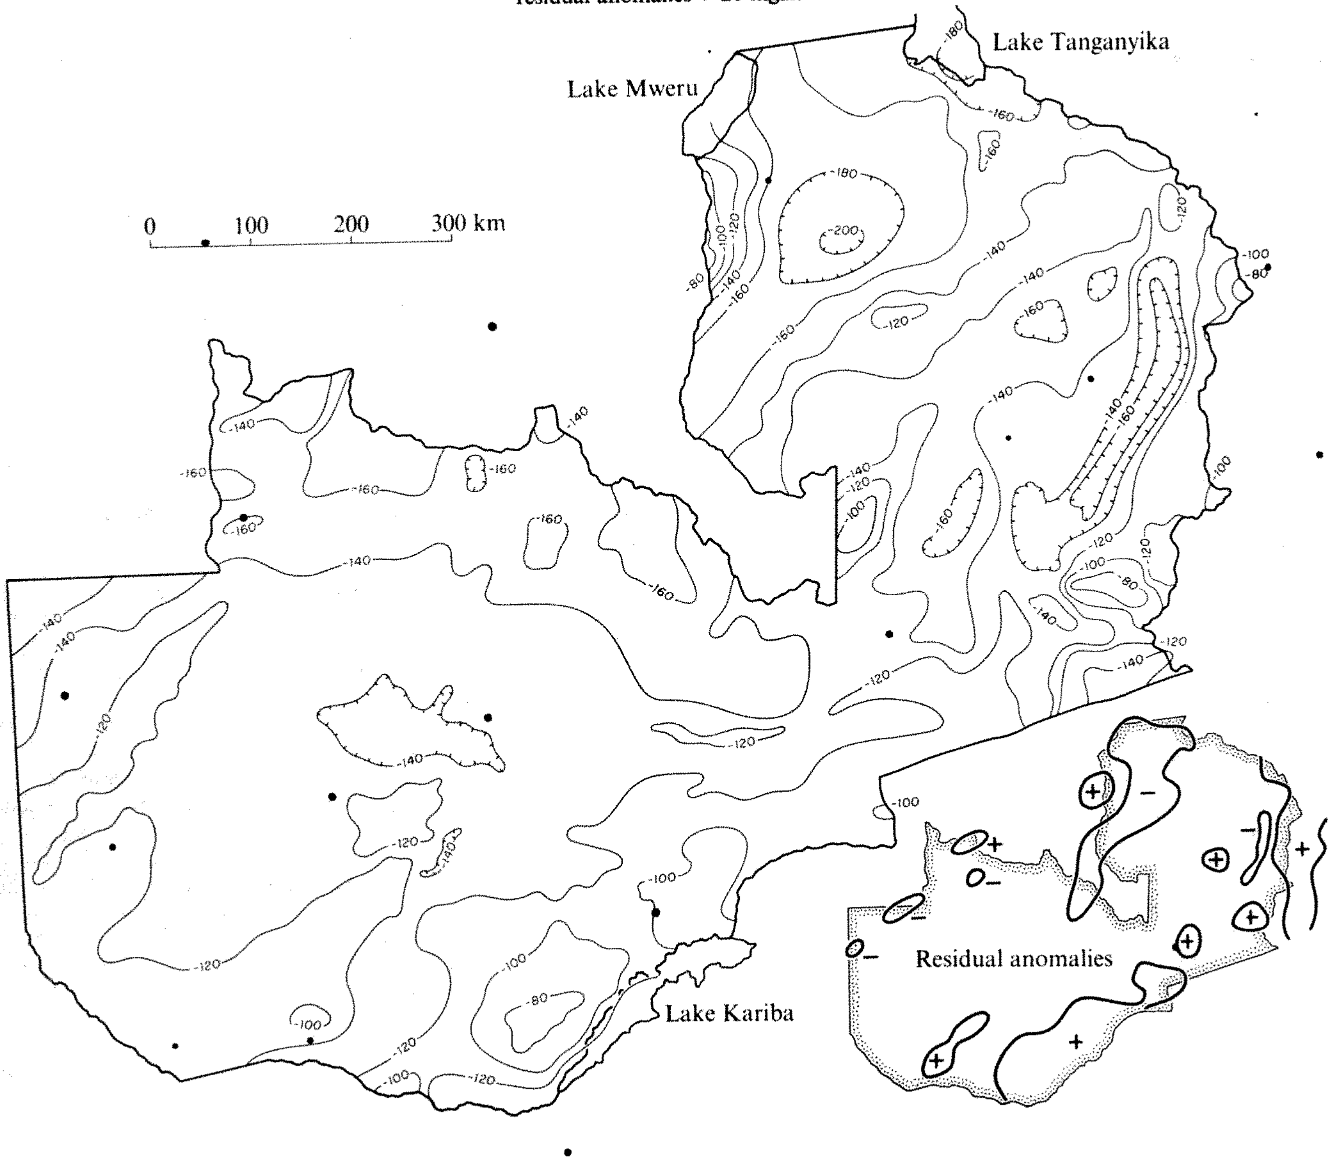
A scatter plot of Bouguer anomalies against elevation is shown in Fig. 2*a*. Stations at <800-m elevation lie exclusively within the Luangwa, Zambezi and Tanganyika troughs, and thus afford an opportunity to compare gravity variations in rift and non-rift settings. Regression lines were fitted to mean Bouguer anomalies and mean elevations in each 100-m elevation interval; these lines are shown in Fig. 2 and their parameters in Table 1, with similar, earlier analyses from east Africa[7,8].

The Zambia and Kenya regression lines have similar slopes in their respective rift and non-rift settings, but the Zambian intercepts in both settings are substantially more negative. The Zambian line for non-rift stations is almost the same as that determined by Woollard for 3°×3° mean anomalies in east Africa.

The different slopes in rift and non-rift areas implies different densities in the two settings, and suggests contrasting crustal and upper mantle structures. The significance of the different intercepts is unclear, but the differences may stem from the fact that in Woollard's[8] and our analyses, the lines were fitted to mean anomalies, while Khan and Mansfield[7] presented a subset of their individual station data, which may be biased away from the regional mean.

Free-air anomalies are also of interest because they can give to a first order an estimate of how closely a region approaches isostatic equilibrium. When isostasy prevails, free-air anomalies are usually less than a few tens of mgal, distributed randomly about zero, and show very little dependence on elevation. Woollard[8] gives an empirical relationship between free-air anomalies and elevation in isostatic regions as $FA = 0.0075h-6$, where FA is the free-air anomaly in mgal and h is the elevation in m.

Fig. 1 Bouguer gravity anomaly map of Zambia. Contour interval 20 mgal. Reduction density 2.67 g cm^{-3}. Inset map shows residual anomalies >20 mgal.



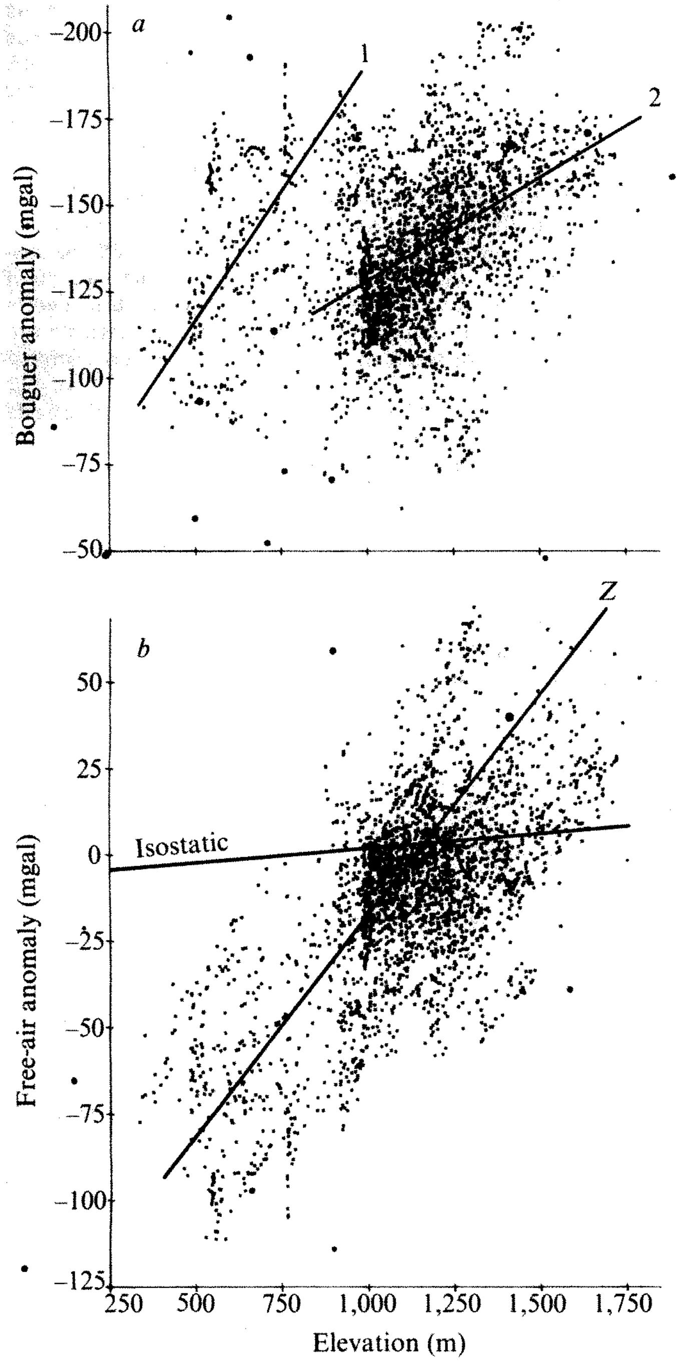


Fig. 2 *a*, Scatter plot of Bouguer anomalies against elevation, with regression lines for rift (1) and non-rift (2) stations. *b*, Scatter plot of free air anomalies against elevation. Line labelled Z represents Zambian data; line labelled 'Isostatic' represents empirical relationship of Woollard[8]. Both lines are fitted to mean anomalies and elevations within 100-m intervals.

Figure 2*b* is a scatter plot of free-air anomalies against elevation for Zambia, and shows a clear departure from the isostatic relationship and an obvious dependence of anomalies on elevation. Such a dependence of free-air anomalies on elevation is not uncommon in regions of considerable relief, but in Zambia, apart from the escarpments adjacent to the rifts, the terrain is very gentle.

It is, therefore, possible that the Central African Plateau may not be in isostatic equilibrium. Woollard[8] notes that a plateau undergoing uplift can exhibit a regional departure from isostasy. Considerable evidence is accumulating that suggests that this part of central Africa is dynamic and responding to tectonic stress. Widely distributed earthquake epicentres[5], tensional focal mechanisms[9,10], anomalous heat flow[11] and disrupted drainage as shown on satellite photography together make an interesting if not compelling case for contemporary tectonism (incipient rifting) in the Central African Plateau. In such a context, it seems possible that isostasy is yet to be fully established in this current phase of tectonism. If tensional block faulting continues, however, and becomes more widespread in the Central African Plateau, a restoration of isostatic equilibrium will probably follow.

Table 1 Regressions of Bouguer anomalies (mgal) on elevation (h, m)

	Zambia	Kenya[7]	East Africa[8] (3°×3° mean anomalies)
Rift	$-0.15h-41$	$-0.137h-4.31$	
Non-rift	$-0.06h-67$	$-0.082h-5.85$	$-0.063h-57$

Electrical conductivity and tectonics of Scotland

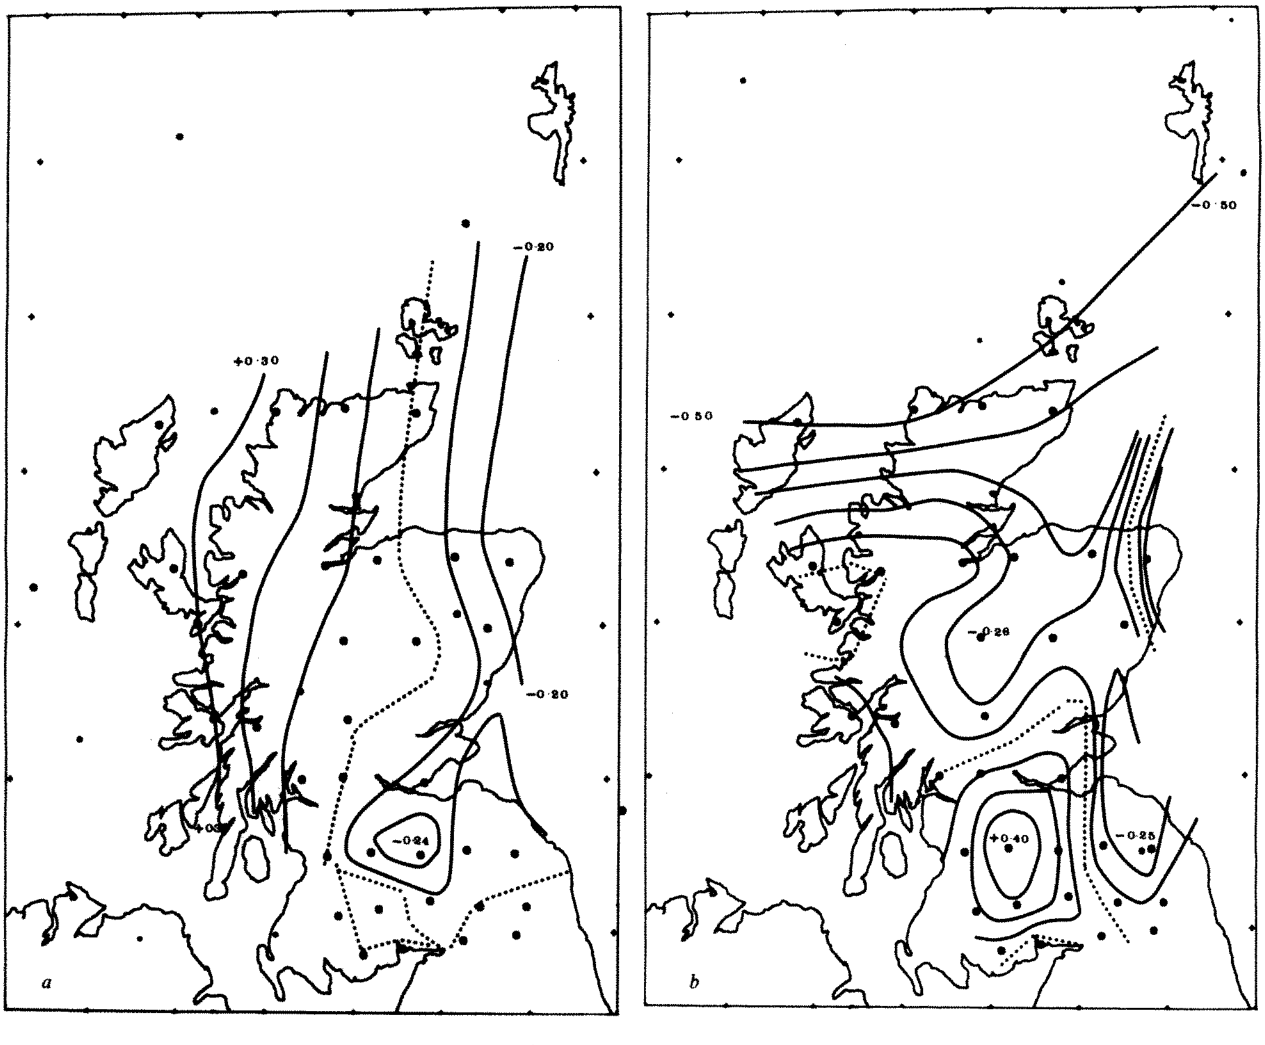
A REGION of anomalously high electrical conductivity in southern Scotland, known as the Eskdalemuir anomaly, has been discovered and mapped, in terms of related anomalies in time-varying geomagnetic disturbance fields[1,2]. Magnetotelluric soundings[3] have indicated the depth of the conductor as 12 km, at which depth Jacob[4] has reported an anomaly in seismic wave velocities. Bamford and Prodehl[5] have also found anomalous seismic wave velocities in this region. In 1973 the University of Edinburgh operated two magnetometer arrays which together covered nearly all of Scotland. In each array 20 three-component recording magnetometers of Gough–Reitzel type[6] were operated for 6–8 weeks. These arrays, together with extended magnetotelluric study of the Eskdalemuir anomaly[7], now make possible a fuller description and interpretation of conductive structures. Data from stations north of the Midland Valley, where only limited geomagnetic variation studies [8,9] had preceded ours, indicate further regions of anomalously high conductivity in Scotland. Full discussion and analysis of these data will be presented elsewhere. This note gives some preliminary indications of these conductivity anomalies and suggests possible tectonic implications.

Time-varying magnetic fields associated with induced currents in the solid earth, which may delineate conductive structures, are superposed on the source field due to currents in the magnetosphere and ionosphere. At the geomagnetic latitude of Scotland, source fields associated with polar electrojet or substorm activity have complicated morphologies, which may make the recognition of internal anomalies difficult. Induction in the Atlantic Ocean and the seas surrounding the British Isles provides an additional complication, particularly at the longer periods. Several techniques have been applied to the interpretation of the very large body of data from the arrays. These include the contouring of amplitudes and phases of Fourier transforms and the mapping of polarisation ellipses and of in-phase and quadrature-phase induction arrows. These procedures have been less successful in Scotland than elsewhere[10–13], presumably because of the superposition of spatially variable fields associated with the source and with the ocean on a complex geoelectric structure in northern Scotland.

One method which has proved useful in indicating the internal conductive structure is that of the hypothetical event[14], in which contoured maps of the vertical magnetic field component, Z, are found for a hypothetical uniform horizontal inducing field in any desired azimuth. If the vertical field can be represented by a linear combination of the horizontal fields, then the transfer functions $A(f)$ and $B(f)$, at the frequency f of the field can be calculated from $\bar{Z} = A(f)\,\bar{X} + B(f)\bar{Y} + \varepsilon(f)$. Here $\bar{X}$ and $\bar{Y}$ are the Fourier transforms at frequency f of the northward and eastward components of the field and $\varepsilon(f)$ is a small uncorrelated residual. By using appropriate values of $\bar{X}$ and $\bar{Y}$ to represent a desired hypothetical field and assuming that $\varepsilon(f)$ is negligible, one can obtain the Z response to the synthetic field using this equation and the estimated values of $A(f)$ and $B(f)$. The transfer functions are estimated from a number of variation events at each station[15]. While to some extent they reflect the relation of Z to X and Y in the source as well as in induced currents, the effect of the source on transfer functions derived from several events of differing source geometries and polarisations is smaller than that on a single event mapped, say, as Fourier transform coefficients. A second advantage of the hypothetical event method is that it substitutes for the natural source-fields, of complicated geometry and polarisation, a uniform, linearly polarised source field, the azimuth of which can be chosen to maximise the induced currents in a given structure. A third advantage is that this method facilitates unified interpretation of the results from the two consecutively-operated arrays.

Contoured maps of Z have been constructed for inducing fields linearly polarised in magnetic N, E, NW and NE azimuths, at periods in the range $300 \leq T \leq 5200$ s. For $T \geq 2400$ s the coastal and source field effects dominate the transfer functions in northern Scotland—as shown in Fig. 1(*a*) and (*b*)—but at shorter periods the internal currents predominate and produce a consistent and conspicuous pattern in the hypothetical-event Z contours in the range $300 \leq T \leq 1000$ s. Typical maps are shown in Fig. 2(*a*) and (*b*) for unit north-south inducing fields of periods 700 s and 1000 s. To a first approximation, a single current concentration produces closely spaced parallel contours in its vicinity. There may be a

Fig. 1 *a*, Z contours for a unit regional horizontal magnetic field directed eastwards. *b*, Z contours for a unit regional horizontal magnetic field directed northwards. In both cases, the values plotted are for the in-phase fields for a period $T = 2400$ s, the contour interval is 0.10 nT and the zero Z contours are represented by the dotted curves.



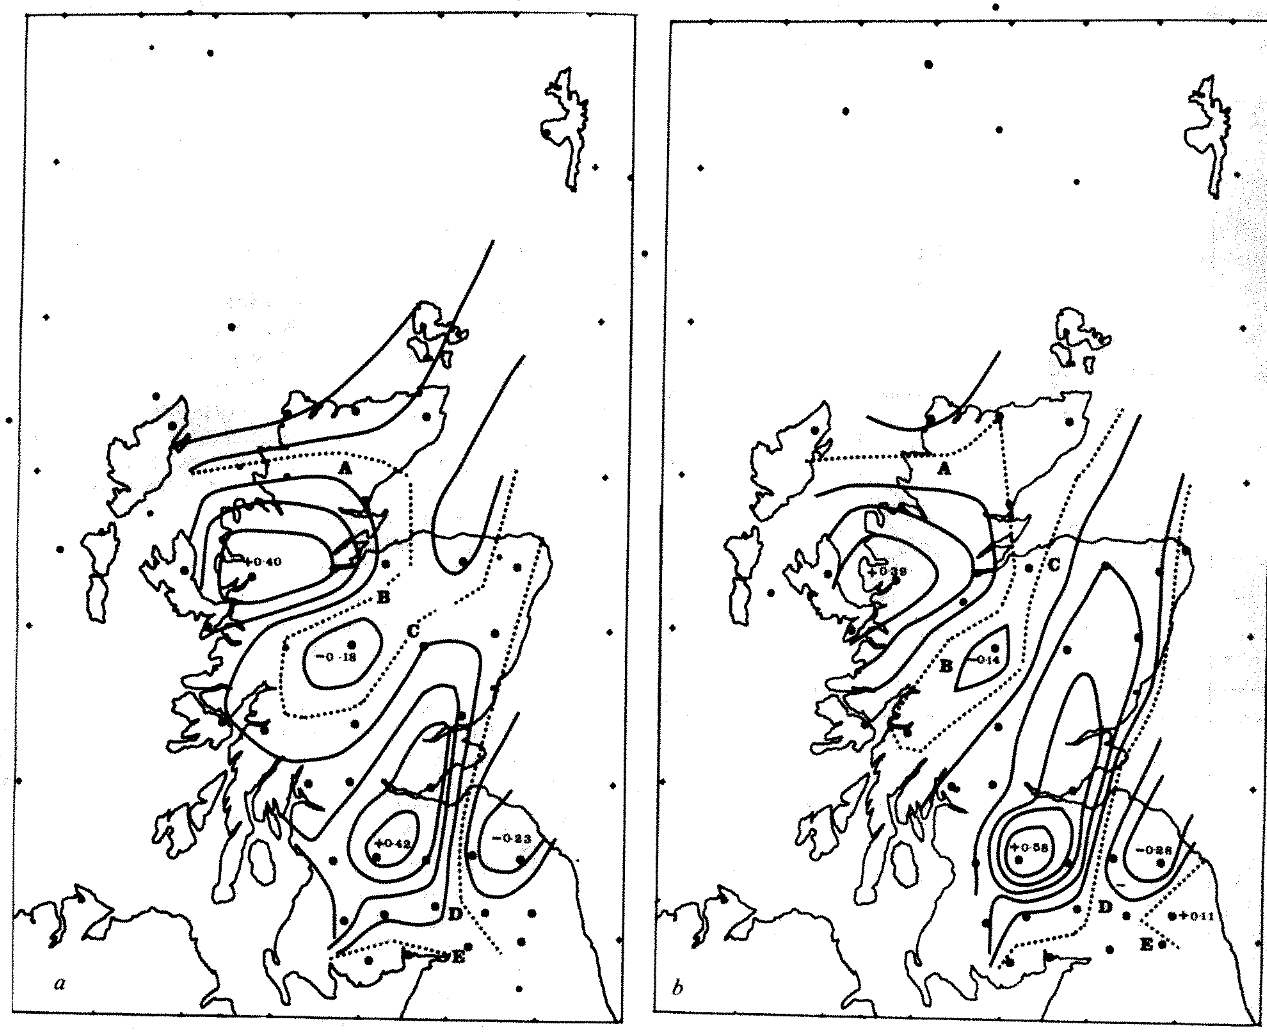


Fig. 2 Z contours for a unit regional horizontal field directed northwards. *a*, In-phase field for a period of 700 s. *b*, In-phase field for a period of 1000 s. The contour interval is 0.20 nT and the zero Z contours are represented by the dotted curves.

roughly central zero contour if there is no large regional gradient in Z due to other currents. In the maps the $Z = 0$ contours are delineated by dotted lines. For more complex current concentrations, the zero contours may not have the same significance. As shown by Bailey and Edwards[16], the Z field gradients are more useful for interpretation in this case. The Eskdalemuir anomaly, which may be associated with two regions of zero Z contours (D and E), is prominent in contour maps at all periods. Three other regions of zero Z contours appear consistently at the shorter periods. The first (*a*) is in the north-west corner of Sutherland, the second (*b*) runs along the Great Glen and the third (*c*) follows a path in eastern Scotland from the Moray Firth to Argyll. The widths of the Z anomalies set maximum limits of about 35 km on the depths of all these conductors, so they are within the crust. The significance of the Z contours is now being studied further and should lead to quantitative modelling of the conductive structures and correlation with other geological and geophysical features. For the present, attention is drawn to the interesting correlation between the three zero Z regions A, B and C (Fig. 2) and two Moinian and one Dalradian ophiolite suites regarded by Garson and Plant[17] as marking former subduction zones. These are indicated schematically in Fig. 3. These zones are associated with intense mineralisation–particularly the Dalradian zone which has, for example, well-defined outcrops of graphitic schists. The Moine belt of ophiolites, proposed by Garson and Plant as a late Precambrian subduction zone (750–800 Myr old), can be correlated in Sutherland with Z zero contour A and along the Great Glen with zero contour B. The third belt C seems to correlate with the Dalradian ophiolites, which Garson and Plant regard as marking a subduction zone active in Cambrian time. The three northern anomalous regions mapped by the magnetometer arrays may thus be related to these ancient subduction zones. It has been suggested that hydrated minerals in ophiolites may be highly conductive[18] but in ancient subduction zones other sources of high electrical conductivity probably exist as suggested by Camfield and Gough[19] for their proposed Proterozoic plate boundary in North America. Garson and Plant have also proposed two younger ophiolite suites along the Highland Boundary and S. Uplands faults but these are much less well defined and have less associated mineralisation. Many questions must be answered, however, before the association between the geomagnetic data and possible subduction zones can be made with confidence in Scotland. Further field observations, already in progress, should enable both the location and depth of the conductive zones to be located more precisely. Magnetotelluric measurements at locations traversing the anomalous regions in N. Scotland—planned to start in 1977—should indicate whether the Z contours should be associated with single or complex conductors. Recent magnetotelluric measurements in S. Scotland should assist in the interpretation of the regions D and E. Our results suggest a more complicated geometry for the Eskdalemuir anomaly than was shown by earlier work[1,2]. There seem nevertheless sufficient

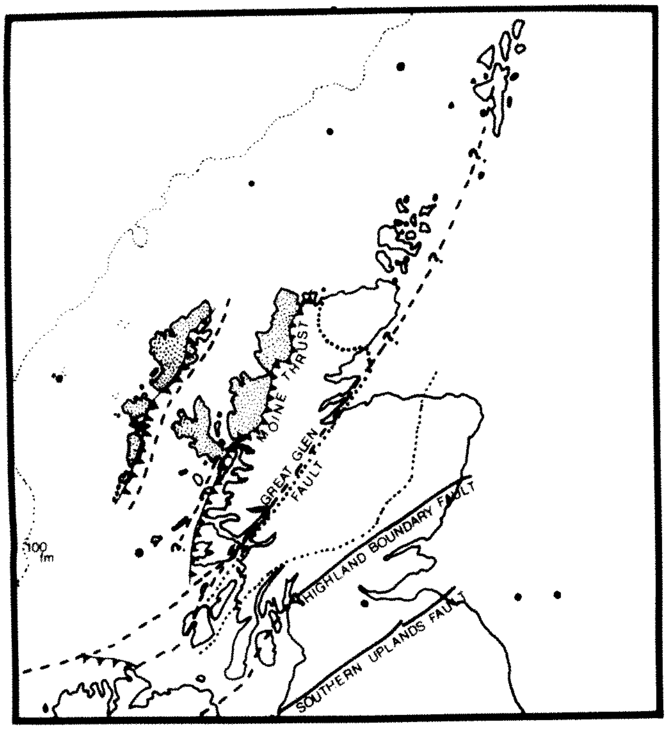

Fig. 3 Simplified tectonic map of Scotland. Shaded region is the Lewisian Foreland. Dotted curve represents ancient subduction zones proposed by Garson and Plant.

grounds to propose that there may be a close relation between the complex electrical structure of the crust in Scotland and past tectonic underthrusts.

Tectonic and sedimentary significance of Cretaceous Tekenika Beds of Tierra del Fuego

STRATA called Tekenika Beds have been considered the oldest post-orogenic rocks within the southernmost Andean Cordillera. Their significance in terms of regional tectonic history outweighs their small outcrop area on the east side of Hardy Peninsula on Hoste Island, Chile, about 160 km north-north-west of Cape Horn (Fig. 1). The Tekenika Beds, which are 2–3 km thick, are best known on Burleigh Peninsula on the south side of Tekenika Bay (Tekenika derives from two Yahgan Indian words *Teke uneka*[1]), where they are largely sandstone and conglomerate (Figs 1 and 2). The basal contact has not been seen; however, the strata, although folded (ref. 2 and unpublished reports of Empresa National del Petroles), are less deformed than the tightly folded Lower Cretaceous Yahgan Formation just north of Tekenika Bay less than 5 km away. Therefore an unconformity is implied. Coarseness of the strata, fossil wood (some bored by worms or molluscs), thin lignitic coal beds, shallow marine molluscs and presence of some plutonic clasts led to the view that the Tekenika is a nearshore, post-orogenic sequence[2]. Suarez and Pettigrew recognise it as pre-orogenic, but still interpret it as a shallow marine deposit[3]. We report here structural evidence indicating that the Tekenika Beds are pre-orogenic and deep water deposits.

Dating of the Tekenika rocks has long seemed important in constraining the younger age limit of Andean orogenesis in Tierra del Fuego. For this reason, Halpern in 1963 collected fossils and igneous pebbles from the Burleigh Peninsula for isotopic dating. His results suggested a very equivocal palaeontological age of 'Late Cretaceous to Early Tertiary', and K–Ar dating of a gabbroic boulder suggested 116 ± 4 Myr (Early Cretaceous) as a maximum possible age[2]. An altered greenstone considered contemporaneous with the lower Yahgan was dated as 92 ± 4 Myr, which was interpreted as being close to the time of folding and metamorphism[2]. The gabbro clasts were considered derived from the Andean batholith complex just to the south-west of Tekenika Bay. Intrusives into the folded and cleaved Early Cretaceous (Neocomian) Yahgan Formation at two localities 50 km north on Hoste and Navarino Islands were also dated as 77 ± 5–81 ± 5 Myr (ref. 2).

The above evidence seemed consistent with the view that the Tekenika Beds represent a post-orogenic molasse. Because neither fossils nor isotopic dates could resolve satisfactorily exactly when the main Andean orogeny occurred between 116 and 77–81 Myr we visited, on a cruise of R. V. Hero, in May–June 1974, all the Tekenika outcrops, hoping to clarify stratigraphic relationships and discover more definitive fossils. Some fossils were found, but the only one of possible stratigraphic significance is a colonial coral fragment from conglomerate on Navidad Bay (Fig. 1). It was identified by A. G. Coates, George Washington University, as *Actinastrea* cf. *A. peruviana*, which is known from upper Aptian- to Albian-aged strata in Peru[4]. We also found *Rotalaria*, *Yoldia*?, a naticiform snail, belemnoids and *Ostrea* fragments. All of the shells and plants were contemporaneous with Tekenika sedimentation, but were swept in like pebbles. All that any of the palaeontological evidence clearly shows is that the strata are Cretaceous.

Having assumed that the Tekenika Beds post-dated the main Andean orogeny in Tierra del Fuego, we were surprised to discover structural relationships that show them to be pre-orogenic instead; that is, late Early Cretaceous to middle Late Cretaceous or post-Yahgan and pre-77–81 Myr. To summarise, Yahgan strata contain Neocomian fossils and lie below the Tekenika beds; the latter contain 116-Myr-old pebbles and a possible Albian–Aptian fossil. Folds and cleavage in the Yahgan are cut by 77–81-Myr plutons, and concordant cleavage was found in the Tekenika. Therefore, the Tekenika Beds are post-Neocomian and pre-77–81 Myr, possibly Albian or Aptian. The Tekenika Beds lie within a synclinorium whose axis trends west-north-west-parallel to more tightly compressed folds in the Yahgan Formation north of Tekenika Bay (Fig. 1). North of Burleigh Peninsula we found alternating sandstones and olive-drab-weathering mudstones concordant with darker, more indurated graywackes and mudstones of the Yahgan Formation (Fig. 2). The basal contact of the sequence could not be located precisely because of intrusive dykes and poor exposures. Similar strata occur south-east of Burleigh Peninsula along Navidad Bay, but relationships of these lower Tekenika Beds to fossiliferous Yahgan strata (or Hardy Formation of

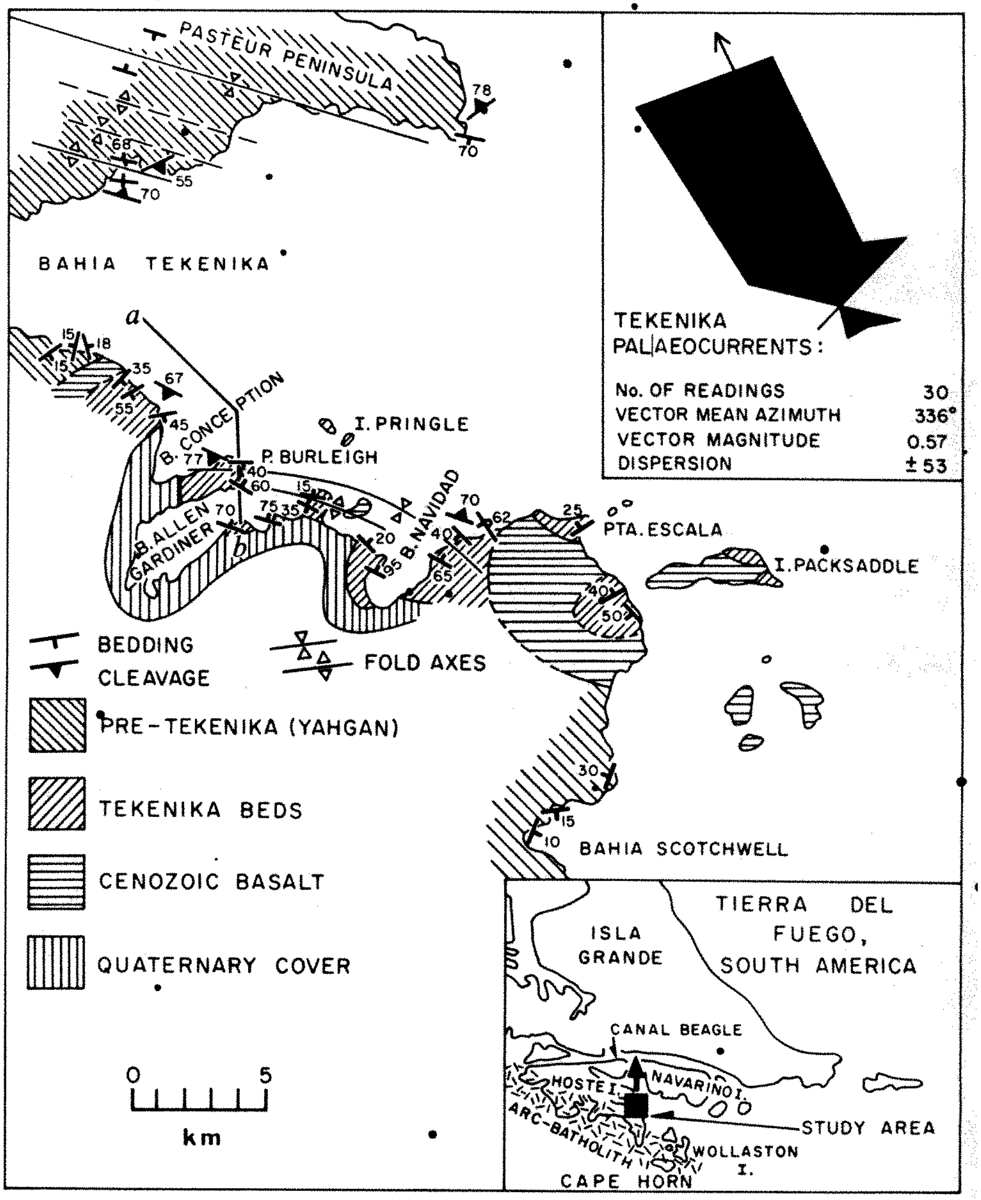

Fig. 1 Schematic geological map of Tekenika Bay area, southern Chile; pre-Tekenika at Bahia Scotchwell includes Hardy Formation of Suarez and Pettigrew[3,8]. Heavy arrow in inset is average Yahgan palaeocurrent direction.

Suarez and Pettigrew[3]) farther south at Scotchwell Bay are obscured by a late Cainozoic basal tcomplex on Punta Escala and Isla Packsaddle (Fig. 1). Our observation of a subtle but definite cleavage in the Tekenika mudstones is particularly significant. Generally the cleavage consists of sporadically developed fractures, but locally it is slaty and parallels the regional slaty cleavage characteristic of the Yahgan rocks to the north.

Throughout this part of the southern Andes, deformation and metamorphism are remarkably heterogeneous, generally diminishing in intensity southwards from a maximum along the north side of Canal Beagle[5–7]. Just north of Tekenika Bay, the Yahgan rocks are tightly to openly folded, with a pronounced slaty cleavage. South of Tekenika Bay, however, at Bahia Scotchwell, for example, folding in the fossiliferous Lower Cretaceous rocks is gentle. The rocks here have a well developed joint system, but slaty cleavage is non-existent. Thus the slight deformation of the Tekenika rocks is consistent with the regional structure. Their less deformed and metamorphosed nature is not the result of a post-orogenic age, as long assumed, but reflects its structural location. We infer that the Tekenika Beds were originally more widespread, and have been preserved due to their location in the axis of a regional synclinorium.

Sedimentologically we also found much similarity with underlying Yahgan flysch strata. Both show the same south–north palaeocurrent pattern (Fig. 1) and both are characterised by graded bedding throughout (Fig. 3); sandstones show typical Bouma sequences in both cases. The Tekenika grades upward from Yahgan-like alternating graywackes and mudstones into thick, crudely graded sandstones with less mudstone, and in turn graded and massive volcanic cobble and boulder conglomerates with some clast imbrication (Fig. 2); sandstones are poorly sorted lithic (volcanic) graywackes with considerable matrix[2,11]. The coarse volcaniclastic deposits have sedimentary structures identical with those of conspicuous andesitic breccias and coarse sandstone zones interstratified within the generally finer Yahgan on western Navarino Island (Fig. 1). Both are generally poorly sorted and show massive as well as graded units. Parallel stratification is very common and some small- and medium-scale cross bedding is present in both cases. Shallow scour structures are present, especially in the Tekenika. Fragments in the Yahgan breccias are much less rounded than in the Tekenika conglomerates, however. Both cases lack abundant medium-scale cross bedding in well-sorted sands, pronounced channelling, fining-upward sequences, extensive organic burrowing of mudstones and *in situ* coals, all characteristic of deltaic deposits. Also lacking are low-angle inclined stratification in well-sorted sands, layers with shell or heavy mineral concentrations and soil profiles characteristic of littoral deposits.

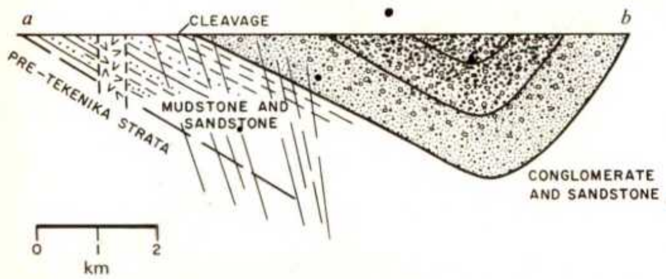

Fig. 2 Cross section of Tekenika Beds along line *a–b* shown in Fig. 1. Note cleavage and a dyke (left) penetrating both pre-Tekenika and Tekenika strata.

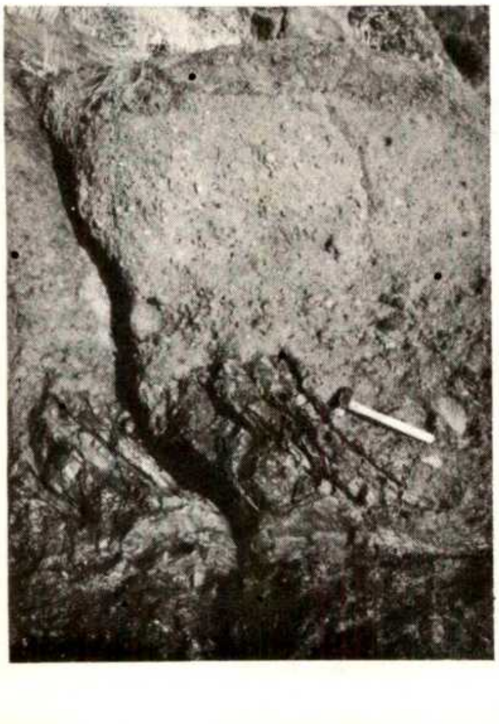
The Yahgan-aged (Neocomian) rocks coarsen southward toward the main Patagonian batholith; they have been named the Hardy Formation[3,8]. Although Suarez and Pettigrew included the Tekenika Beds in their Hardy formation, we consider the former a member of the Yahgan formation because it shares deeper-water characteristics, structural concordance and grade of metamorphism with the Yahgan. Sedimentology of the Hardy rocks and their relationships to the Tekenika are not yet well documented. Just south of Scotchwell Bay are pillow lavas and volcanic breccias interstratified with Yahgan-like mudstones, sandstones and volcanic conglomerates containing marine Lower Cretaceous fossils. Near the southern end of Hardy Peninsula (inland from Orange Bay) we observed apparently non-marine silicic breccias with accretion lapilli and welded tuff zones interstratified with mafic and intermediate breccias and vesicular flows. The same assemblage occurs also on the Wollaston Islands 100 km to the south-east (Fig. 1). These volcanic rocks are of uncertain age, but the simplest hypothesis is that they comprise part of the Early Cretaceous volcanic arc complex. Cross-bedding orientations within coarse green sandstones indicate south–north palaeocurrents, which agree with those of the Yahgan and Tekenika strata.

Fig. 3 Graded Tekenika conglomerate with large ripped up mudstone block at base.



There are two laterally-equivalent Cretaceous sedimentary facies in southern Tierra del Fuego, which were both derived from an arc source—the generally finer Yahgan (north) and the coarser conglomerates and breccias (south)[9]. This situation is duplicated in equivalent rocks of South Georgia Island now 2,000 km to the east, but which is interpreted as originally having been adjacent to Navarino Island[5]. Significantly, the structural situation on South Georgia and Annekov Island is also similar to that in Tierra del Fuego, in that mid-Cretaceous deformation was concentrated towards the north, while sedimentary and igneous rocks deposited in and immediately behind the volcanic arc are only gently deformed[5–7,10,11].

We interpret the Tekenika Beds to be late Early to early Late Cretaceous in age, and to represent the youngest recognisable part of a continuous coarsening-upward (and southward) volcaniclastic succession. The typical Yahgan flysch to the north comprises submarine fan deposits debouched into a relatively deep, narrow marginal or back arc basin[9–11]. We believe the Tekenika was deposited in a similar setting, but the coarse, upper Tekenika must represent an upper fan channel or suprafan lobe closer to the volcanic arc source than most of the Yahgan. The heterogeneous breccias, tuffs and flow rocks of southern Hoste and the Wollaston Islands (Hardy Formation) presumably were deposited within the arc itself; the batholiths are the roots of the arc[5,8,11]. The Tekenika conglomerates and sandstones were derived from rocks such as these, and were redeposited below wave base rather than on deltas and shorelines. This is based on the prevalence of graded bedding and the fact that all of the plant and invertebrate material has clearly been transported. Land-derived logs up to 4 m long and oriented by currents as well as shallow-marine shells occur within conglomerates and coarse sandstones; the lignitic coal occurs as lenticular seams only a few cm thick at the tops of graded units. Rounding of the Tekenika gravel indicates derivation from beach or stream gravels formed originally on volcanic islands. Rare chaotic pebbly mudstones (diamictites) indicate mass gravity flows, while the graded conglomerates of both the Yahgan and Tekenika indicate transport by less viscous turbidity currents, debris flows or other gravity-driven mechanisms. Such resedimented conglomerates have received considerable study in recent years, and are proving to be rather common in rock sequences like those of the southernmost Andes.

Rapid removal of plutonium from the oceanic surface layer by zooplankton faecal pellets

It is possible that increasing quantities of plutonium will be introduced into the marine environment, so detailed knowledge of the oceanic behaviour of this element is highly desirable. The levels of plutonium in sea water and marine organisms have been established in a general way[1,2], and suggestions have been made as to possible transport mechanisms. Noshkin and Bowen[3] proposed a model which associates plutonium with a mixed population of particles, sinking at rates of 70–392 m yr^{-1}, and Folsom *et al.*[4] suggested that algae and, perhaps, the main phytoplanktonic biomass may have an important role in determining the chemical and physical forms of plutonium predominant in the ocean. The role of the zooplanktonic biomass has not been investigated in detail, but it is known that for several elements zooplankton metabolism may be an important biological factor in the removal of the elements from the surface layer of the ocean to depth[5–9]. The particular importance of zooplankton faecal pellets in this process has been highlighted, and the faecal pellets of a common zooplanktonic species, the euphausiid *Meganyctiphanes norvegica*, have been shown to be rich in the important naturally-occurring alpha-emitter ^{210}Po when compared with whole organism levels[10]. We have performed a similar study for plutonium, and we report here that *M. norvegica* faecal pellets are indeed relatively rich in plutonium, and suggest that zooplankton faecal pellet deposition might be an important vector in the vertical oceanic transport of the element.

The environmental levels of plutonium are extremely low, and collection of adequate sample material was a major problem; a faecal pellet collection system was devised[11] which provided us with faecal pellet samples of about 100 mg dry mass. Oven-dried samples were acid-digested, treated with hydrofluoric acid, and then subjected to previously described ion exchange techniques[12] to isolate plutonium; ^{236}Pu was used as a spike. Thin sources were prepared and counted by α-spectroscopy. Exacting chemistry was necessary to achieve consistently low 'blank' counting rates, and long counting times were commonplace. The results are given in Table 1, together with the $^{239+240}$Pu concentrations in whole euphausiids, euphausiid exoskeletons collected by dissecting 336 euphausiids, and in a bulk sample of microplankton which serve as food for *M. norvegica*. We found that the concentrations in faecal pellets, although varying widely, were two orders of magnitude larger than those in whole euphausiids and an order of magnitude higher than in the typical food organisms; plutonium levels in the faecal pellets were in fact vastly in excess of those found in typical marine biological materials[2].

What are the implications of these high concentrations in faecal pellets for the flux of plutonium through living euphausiids? A plutonium atom ingested or absorbed by a living euphausiid can be eliminated from the animal by faecal pellet excretion, by moulting, by egg production or by soluble excretion; alternatively, it can be assimilated during growth in one of the organs or tissues and remain in the animal. We calculate the flux of plutonium in a living euphausiid by using available biological data[9] for *M. norvegica*. We multiply the typical faeces production rate, 0.038 g dry faeces per g dry animal per day, by the mean plutonium concentration in faecal pellets given in Table 1. We multiply the moulting rate, 0.009 g dry moult per g dry animal per day, by the concentration in the euphausiid exoskeleton. Collection of eggs in sufficient quantity is an unrealistic task; fortunately, the egg production rate[9,10], about 0.002 g dry eggs per g dry animal per day, is low, and trace element concentrations in eggs are usually unexceptional. It is extremely unlikely that this term will contribute significantly to the flux. To estimate the loss by soluble excretion we performed experiments of a type previously described for other elements[10], using live euphausiids labelled with ^{236}Pu, and found a soluble fractional excretion rate of 0.08 ± 0.02 per day. This value multiplied by the plutonium concentration in whole euphausiids gives the flux loss by soluble excretion. Finally, the amount of assimilated plutonium is obtained by multiplying the whole animal concentration by 0.015 g dry mass increase per g dry animal per day, an average growth rate for non-larval individuals.

Table 2 Flux rates for various transfer modes of plutonium through living euphausiids*

	$^{239+240}$Pu (pCi kg^{-1} d^{-1})
Faecal pellets	5.4
'Moults'†	0.011
Soluble excretion	0.032
Assimilation	0.006

*The flux rates listed in this table and discussed in the text represent three output fluxes plus the assimilation. The sum of these four terms must of course equal the input flux rate, which represents the plutonium taken up by the animal from both water and food. No information about the input via the water route is available, and at this stage only a crude estimate of the input from food can be made. This is done by multiplying the known food ingestion rates for *M. norvegica*, namely between 0.113 and 0.320 g food per g dry animal per day (ref. 9), by the plutonium concentration in microplankton given in Table 1. The result is a 'food only' input flux rate of between 0.6 and 1.6 pCi plutonium per kg per day, which is of the same order of magnitude but less than the estimated total output flux rate of over 5 pCi per kg per day. Fairly wide variation of element concentrations from one microplankton sample to another is, however, to be expected[19]; a more specific identification of the *M. norvegica* food as well as further determinations of the plutonium content of faecal pellets will be needed before the flux balance can be checked accurately and the relative importance of the food and water intake routes assessed.

†The flux via 'moults' quoted above is of course only an approximation, since the concentration in true moults may not necessarily be the same as in the exoskeletons which formed our sample. We have not yet been able to collect euphausiid moults in sufficient quantity to detect plutonium, but we hope to do so in the future; it is, however, very unlikely that the argument which we give in the text will be altered substantially.

The results of these flux calculations are given in Table 2. The complete dominance of the faecal pellet term is immediately obvious, and indicates that 99% of the plutonium taken up by *M. norvegica* is excreted in the faecal pellets. Euphausiid pellets sink fairly rapidly[13], at rates ranging from 126 to 862 m d^{-1}, and they decompose relatively slowly[8]; it seems clear that they have the potential to reach the sea bottom in most areas. If the *M. norvegica*

Table 1 Concentrations of $^{239+240}$Pu in zooplanktonic material and microplankton

Sample	Wet–dry weight ratio	Individual determinations* pCi kg^{-1} dry	Mean pCi kg^{-1} dry
Whole euphausiids	4.7	0.32 ± 0.08; 0.47 ± 0.08	0.4
Euphausiid exoskeleton	4.3	1.2 ± 0.4	1.2
Euphausiid faecal pellets†	4.4	310 ± 50; 76 ± 8; 39 ± 14	142
Microplankton‡	10.7	4.9 ± 0.8	4.9

*Each individual determination is in fact the mean of two determinations made on the two halves of a split sample.

†High concentrations of certain trace elements[9,18] and radionuclides[19] in faecal material brought about by biological amplification processes have been noted previously. The fact that the plutonium concentration in the faecal pellets is higher than that in the food is simply a reflection of a high discrimination factor against a biologically non-essential element.

‡Principally small crustacea, phytoplankton and detritus collected with 65-μm mesh size plankton net along with the euphausiids.

data can be considered as typical of the marine zooplankton biomass as a whole, we can make a rough estimate of the removal time[10] of plutonium from the upper mixed layer of the ocean by zooplankton faecal pellets alone. We multiply the faecal pellet flux rate from Table 2 by 10^{-4} kg m^{-3}, a reasonable, if controversial, estimate[10,14–16] of the dry zooplanktonic biomass in the upper mixed layer, and divide this product into 0.7 pCi m^{-3}, a typical value (ref. 2) of the $^{239+240}$Pu concentration in surface sea water. The result is 3.6 yr, a figure which one would like to compare with estimates of the removal time of plutonium from the upper mixed layer by all routes. Unfortunately, direct quantitative estimates of this quantity are not available; the indications[3,17] are, however, that it is short—of the order of 1 yr. Our estimate for the removal time due to zooplanktonic faecal pellets alone is of the same order, suggesting that faecal pellet removal has a significant role in the removal of plutonium from the surface layers of the sea. Investigations of possible competing removal routes (for example sinking phytoplankton detritus, large inorganic particulate settling) are needed to substantiate this suggestion.

Growth rate and longevity in *Drosophila melanogaster* and *Tribolium castaneum*

THERE are two main groups of hypotheses concerning the mechanism of ageing and death. The stochastic hypothesis assumes that ageing is due to the progressive deterioration of the metabolic machinery caused by the random accumulation of disturbances in one or the other of the cellular macromolecules. This hypothesis has been subject to many experimental tests, but is not yet supported by conclusive evidence. The developmental hypothesis of ageing considers senescence and death as the programmed ultimate stage of differentiation and development. Few experiments have been designed to test that last hypothesis. In two species of insects, *Drosophila* and *Tribolium*—classical tools in genetical research—we tried to verify the hypothesis which relates development to ageing. In *Drosophila* we looked at the variations of longevity linked to experimentally induced variations of one of the important components of development, namely growth rate. In *Tribolium,* we studied variations in longevity associated with the natural variations of growth rate of various ecotypes. In both cases there are clear relations between pre-imaginal growth rate and adult longevity.

Ageing and death, at the level both of the cell and of the organism, are generally considered to be the consequences of a loss of molecular information. Information loss is considered as either the result of random events or as linked to development and therefore as the programmed endpoint of differentiation. Certain previsions of the modern stochastic hypothesis—the error–catastrophe theory[1]—have been confirmed by experiment, but available evidence remains inconclusive[2,3]. The developmental theory of ageing on the other hand is not easily tested by experiment. Yet as early as 1963, Muller[4] stated that spontaneous ageing is part of normal development, that is, that development is a continuing process of which senescence forms the last stage or, in other words, that ageing is a built-in consequence of differentiation. From the latter considerations it has been deduced, correctly but probably incompletely, that the only likely way of prolonging lifespan involves a stretching of the developmental programme, essentially through a prolongation of immaturity[5]. Such a prolongation of total lifespan through a serious prolongation of immaturity, but at the sacrifice of part of the adult longevity, is not entirely unknown; it was repeatedly obtained, for instance in rats receiving various incomplete diets during adolescence[6,7]. We may ask, however, how far does interference with the development and differentiation of an organism during adolescence have any paramount effect on the future and latest steps of life? Indeed at that stage of life, differentiation and development are almost complete. Interference during the earliest embryonic stages of life seems more promising. Poikilotherms thus seem more suitable than homeotherms for use in testing a programmed senescence theory of ageing, simply because the early developmental homeostatic mechanisms of poikilotherms are not strictly regulated, although there is good evidence for temperature acclimation.

The adult longevity of a single genotype of *D. melanogaster,* samples of which had been grown in a large array of pre-imaginal environments known to induce variations in both size and duration of development, was measured in a single controlled environment. The growth rate, estimated by the ratio of thoracic size to duration of development, was negatively and highly significantly correlated to longevity[8] (Fig. 1*a*). In explaining the results the authors supposed that adult longevity is determined early in life by a defined programme. They further argued that this programme and growth rate could be concomitantly modified by varying the preadult environment. These findings apparently imply that within a species the variations in growth rate, characteristic of the various races of that species, should be reflected in the variations of the average longevities of those races. To test this deduction we studied the growth rate and adult longevity of various genotypes of *T. castaneum*—wild strains from wide geographic origin[9]—in a single controlled environment.

The environmental conditions were 33 °C, 70% relative humidity and standard medium of 95% whole wheat supplemented with 5% dried yeast. Growth rate was measured as the weight of the larva at a fixed time, the thirteenth day of the larval stage. Adult longevity was estimated during a maximum period of 227 d. Figure 1*b* shows the relationship between preimaginal growth rate and adult longevity of eight wild strains of *T. castaneum.* The variations in both traits are quite large and the relationship between them is positive and highly significant ($r=0.833$; $n=8$; $P<0.01$). It should be emphasised that there is no strong correlation between longevity and development time ($r=0.569$; n.s.) or adult weight ($r=-0.188$; n.s.) (ref. 9).

Thus in *Drosophila* an artificially obtained decrease in growth rate of a single hybrid genotype results in an increase in adult longevity, whereas in *Tribolium* the natural variations in growth rate of various wild genotypes are positively correlated with longevity. Except for those differences in experimental approach *Tribolium* and *Drosophila* differ at least in three major ways directly related to growth rate and ageing. First, duration of development in *Tribolium* seems to be under polygenic control[10], whereas in *Drosophila* selection for fast or slow development is generally unsuccessful[11]. Second, the imaginal longevities of both species are quite different; in optimal conditions the average longevity of *Drosophila* is about 50 d but in *Tribolium* it is rather more than 130 d. Third, and most importantly, in contrast to *Drosophila*[12], somatic cell division apparently occurs during the imaginal stages of the life cycle of *Tribolium*[13].

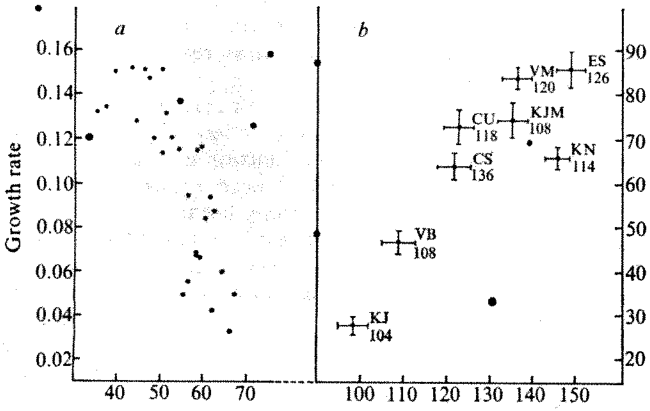

Fig. 1 *a*, Adult longevity as a function of growth rate in *Drosophila* ($r = -0.801$; $n = 28$; $P < 0.001$). Growth rate is estimated as the ratio between the cube of the thoracic size and the duration of development. Longevity is measured at 25 °C on 14 samples of two reciprocal hybrids raised in various pre-imaginal environments—six different temperatures, eight different pre-imaginal population densities—which are known to modify both the size and the duration of development of the treated individuals (redrawn from ref. 8). *b*, Adult longevity ± standard error plotted against growth rate, measured as mean 13-d larval weight, of eight wild strains of *T. castaneum*. The strains are identified according to their geographic origin as: CS (Capetown, South Africa), CU (Chicago, USA), ES (Edinburgh, UK), KJ (Kyoto, Japan), KJM (Kingston, Jamaica), KN (Kano, Nigeria), VB (Vicosa, Brazil) and VM (Veracruz, Mexico). Longevity measurement is based on observing adult death every 10 d up to a maximum of 227 d from egg. This period covered most of the adult death for all strains and the percentage of adults still alive after this period (with a maximum of 18% for ES) is highly correlated with the longevity estimates ($r = 0.840$; $n = 8$; $P < 0.01$). Numbers indicate the sample size of each strain.

In *Drosophila* longevity thus seems to depend negatively on growth rate. Growth rate is the productivity per unit of time, the resultant, due to genotype-environment interactions, of anabolism and catabolism. Growth rate may be associated with mitotic division rate. When growth rate is accelerated or decelerated it may, as a first approximation, be admitted that the same happens for mitotic division rate. Bozcuk[12] has demonstrated that the tissues of *Drosophila* show no mitoses after emergence of the imago, so the death of the organism must, to a certain extent, coincide with cellular death, or at least with the death of a certain number of cells.

It is known from studies carried out *in vivo* in higher organisms that, when a cell enters the ageing pathway, it has a life expectancy which is characteristic of the tissue[14]. When the mitotic rate of the tissue is high, as in the intestinal lining, the life expectancy of the functional cell is only a few days; when it is moderate, as in epidermis, the life expectancy may be a few weeks; and when it is low, as in liver, the life expectancy may exceed 1 yr. Furthermore, artificial prolongation of the epidermal cell life, and of the liver cell life, may be obtained in conditions of stress which provoke a decreased mitotic rate[14]. These relationships between growth rate, mitotic division rate and longevity do not necessarily demonstrate the validity of the developmental theory of ageing, nor do they exclude the error-catastrophe theory. On the one hand, in relation to the developmental theory it may be supposed (as was done to explain the influence of preimaginal temperature on adult life-span[15]) that the growth rate affects the type of molecules that are synthesised and the rates at which these molecules carry out metabolism. If the idea of morphogenes[16] is accepted, it may then be supposed that variations in the type of molecules present in a cell affect the course of differentiation and development. Variations in the molecular composition of a cell as a function of growth rate are not unknown; in *Escherichia coli* for instance the protein composition of the ribosomes varies as a function of growth rate[17]. A changing growth rate could thus result in a different cytoplasmic molecular composition or configuration which could explain an earlier or later programmed death of the cells and of the organism. On the other hand, if a slower mitotic rate is accompanied by a lower number of errors of replication (a point which as yet has not been demonstrated) this could explain a later, randomly provoked unprogrammed cellular and organismic death.

In *Tribolium*, where mitotic divisions do not cease after emergence[13], growth rate is, in contrast to *Drosophila*, positively correlated with adult longevity. So it seems that a faster growth rate, resulting probably in a shorter cellular life expectancy, must be associated in a certain number of stem cells with a higher potential number of cell divisions. The death of the individual will not coincide with the death of some particular cells but with the end of mitotic divisions in particular stem cells. Although the problem has been studied, little is known about the *in vivo* limited or unlimited lifespan of particular stem cells[18]. One may thus hypothesise that a modification in mitotic rate, through a modification of an asymmetrical type of mitotic division[19], may result in a modified cytoplasmic molecular composition or configuration, with possible implications on cellular fate.

Albedo measurement for remote sensing of crop yields

Any remote sensing programme designed to estimate regional agricultural productivity has three major requirements. First, the crops present must be identified; second, the amount of land planted to each type must be determined, and third, the yields of the crops per unit land area must be evaluated. The large area crop inventory experiment (LACIE) uses measurements of reflected solar radiation to fulfil the first two requirements in a true remote sensing context, but to establish yield, LACIE relies on statistical and climatological models largely dependent on ground-based observations[1]. Here we report the basis for a crop yield prediction programme that is not subject to this restriction. Working with wheat, we have shown that the intensity of reflected solar radiation can be used to evaluate crop yields per unit land area. Linked to a satellite system, this could make the worldwide surveillance of agricultural production a technological reality that could greatly stabilise erratic fluctuations in world grain trade of the type which have recently disturbed the world economy.

On 3 December 1975, a 72 × 90-m field of Avondale loam that had been given an initial application of nitrogen fertiliser was planted with spring wheat (*Triticum durum* Desf. variety Produra). The field was then divided into six nearly equal north–south oriented rectangular plots. Five days after planting, each plot was irrigated with 10–12 cm of water. There was no further irrigation until 83 d after planting, when a programme was started to develop six soil water content regimes, as shown in Fig. 1. Each irrigation usually supplied about 10–12 cm of water. The few rains supplied a total of 4.7 cm.

The albedo data plotted on Fig. 1 were obtained from measurements of incoming and reflected solar radiation over each plot, as determined by one upright and six inverted Eppley pyranometers located about 50 cm above the top of the crop canopy. The data were recorded every 20 min, summed to give daily totals to determine mean albedo values, and then normalised as described before[2] to remove variability caused by the changing altitude angle of the Sun during the growing season.

Twice weekly, green leaf area index (the ratio of green leaf area to the area of soil supporting its growth) was measured on three randomly selected plants per plot with an optically integrating area meter. When the heads emerged, three other randomly selected plants from each plot were sampled to determine mean head weight after driving off moisture by drying in an oven. To express these data per unit soil area, as in Fig. 2, at the end of the growing season we hand-harvested wheat from 14-m^2 sections of each of the six plots and counted every plant to obtain the number per unit soil area.

Figure 1 reveals a decline in albedo as the season progresses. Figure 2 shows that this is due initially to the growth and proliferation of the leaves (as they progressively shut out more and more of the high-albedo soil from view) and finally to the growth and proliferation of the plant heads (which start about day 100, when green leaf area has either reached a maximum or begun to decrease).

These relationships are shown more clearly in Fig. 3, where albedo data are first plotted as a function of green leaf area index until day 95, and then as a function of head dry weight from day 105 to near the end of head growth (when final increases in albedo began). The strong linear relation supports the idea that final grain yield is a linear function of the minimum albedo reached just before the large increases that occur as the heads begin to ripen. Comparison of these two parameters (Fig. 4) suggests that the hypothesis is verified by our data.

This analysis shows that measurements of reflected solar radiation can be used to estimate agricultural productivity in a complete remote sensing context. Our approach makes use of ground-based measurements of incoming solar radiation

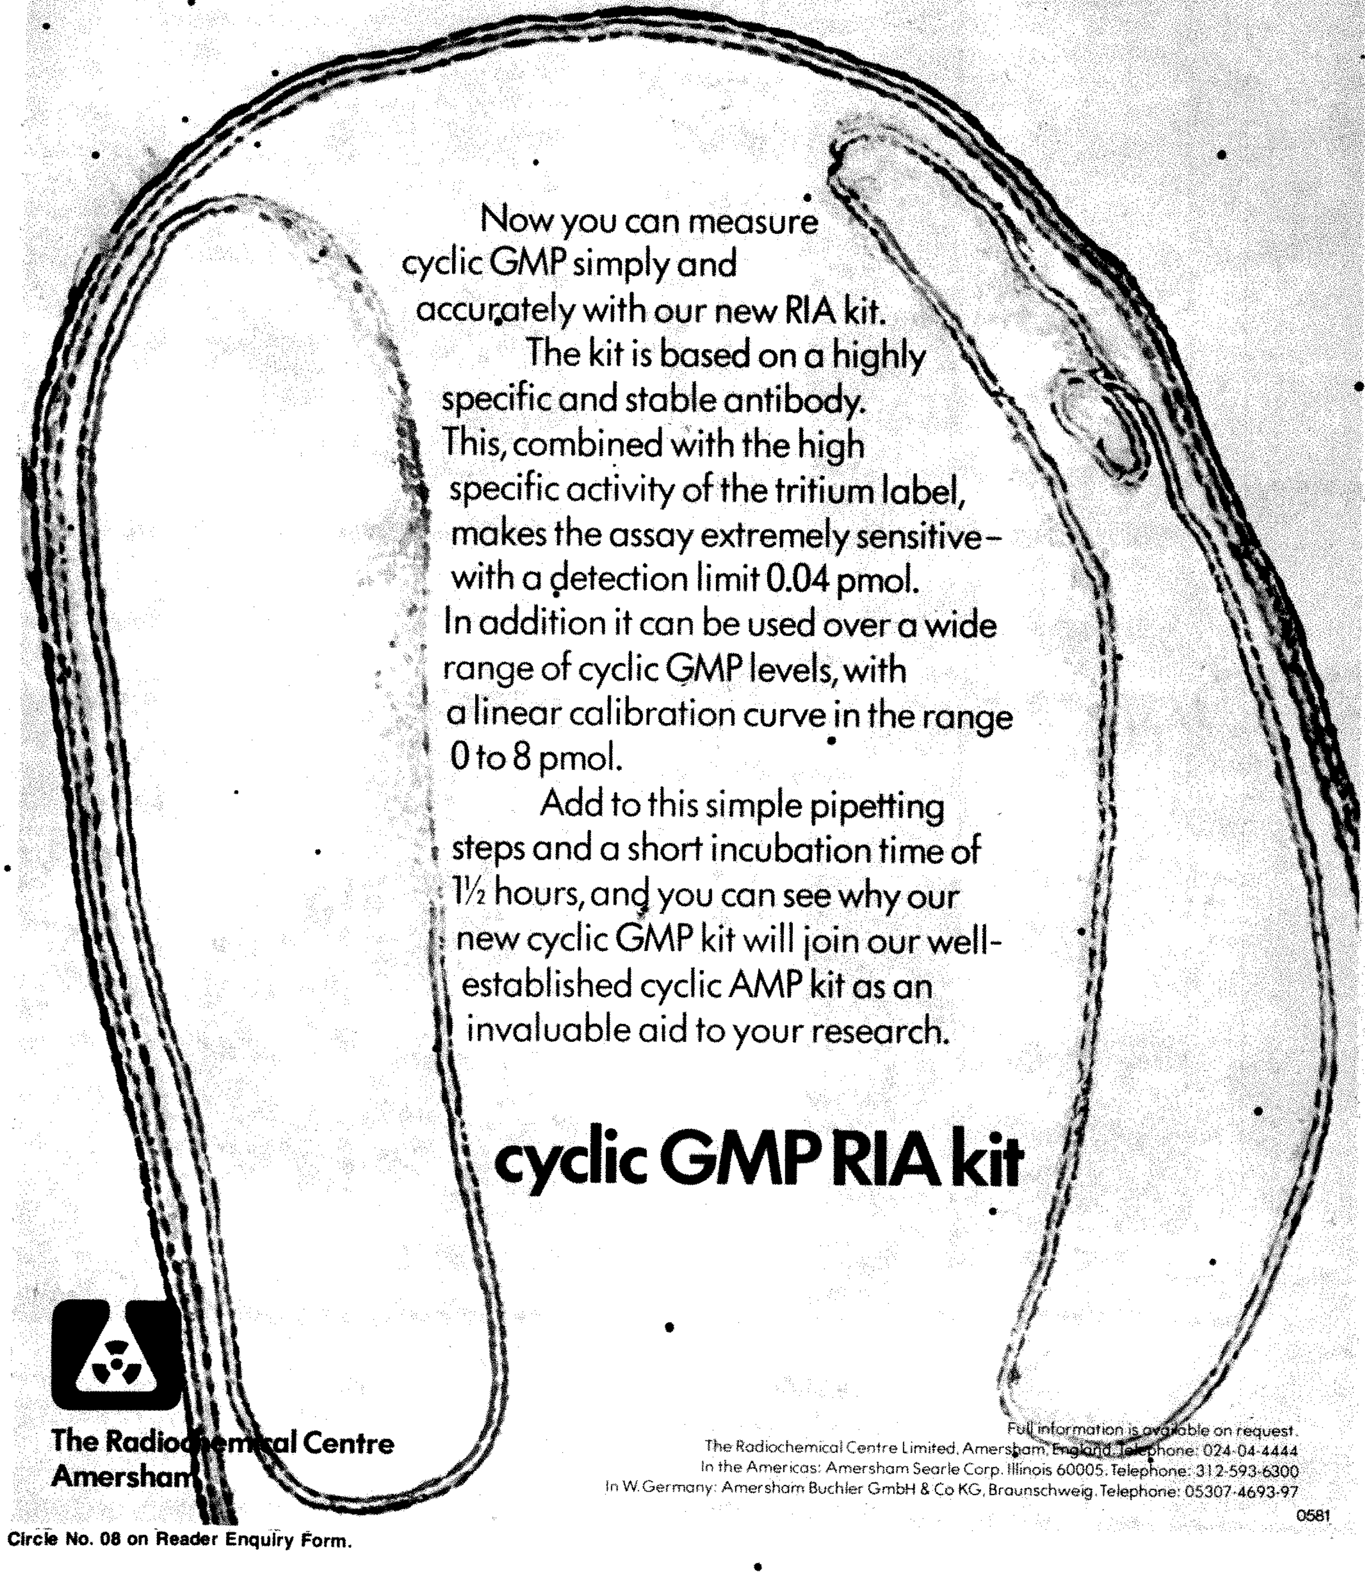
NOW IT'S SO EASY TO MEASURE CYCLIC GMP



Now you can measure cyclic GMP simply and accurately with our new RIA kit.

The kit is based on a highly specific and stable antibody. This, combined with the high specific activity of the tritium label, makes the assay extremely sensitive– with a detection limit 0.04 pmol. In addition it can be used over a wide range of cyclic GMP levels, with a linear calibration curve in the range 0 to 8 pmol.

Add to this simple pipetting steps and a short incubation time of 1½ hours, and you can see why our new cyclic GMP kit will join our well-established cyclic AMP kit as an invaluable aid to your research.

cyclic GMP RIA kit

Cutrock equipment
is now available
from **ELE**

ELE is one of the World's leading suppliers of equipment for the testing of soils, concrete, asphalt and related materials used in Civil Engineering.
We have now extended our field of activity to include selected items of Cutrock equipment, acknowledged as being some of the finest in the world.
The range covers

- **Geological hammers**
- **Rock splitting and crushing**
- **Core drilling**
- **Rock and core cutting**
- **Thin section cutting and grinding**
- **Lapping and polishing**

For a comprehensive brochure on ELE-Cutrock equipment, please contact

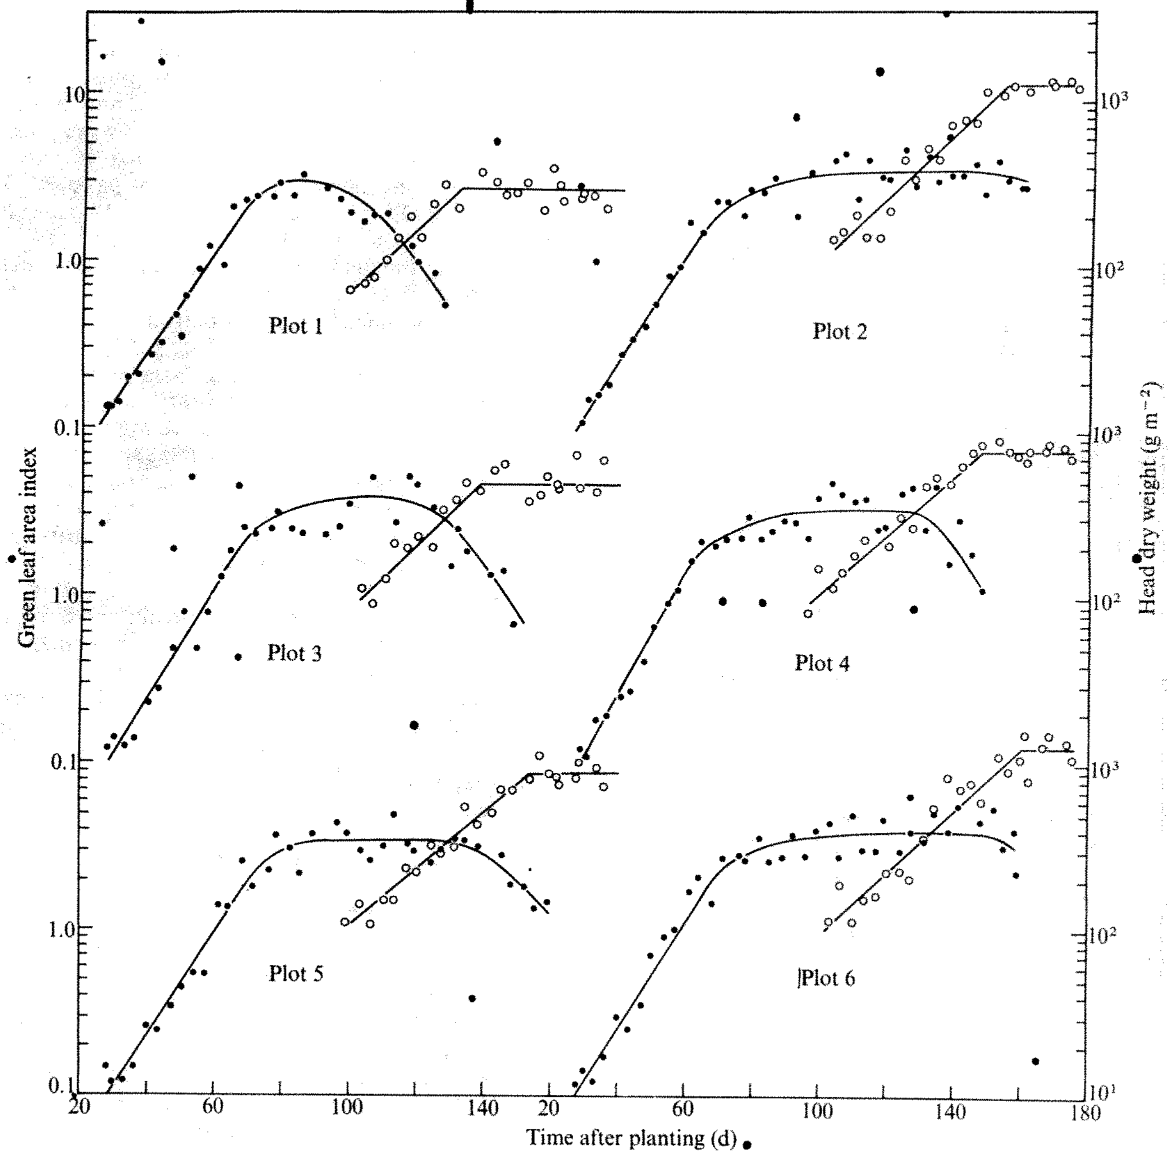

Fig. 2 Green leaf area index (●) and head dry weight (○) accumulation of six differentially-irrigated plots of Produra wheat grown at Phoenix, Arizona as a function of days after planting.

to standardise our data in an albedo format; but many other means of standardisation could be used which do not require ground-based measurements. Normalisation to some constant albedo feature such as a dry lake bed, a rock outcrop, a non-eutrophic lake, or even a man-made surface could be accomplished entirely by remote sensing. In such a programme, however, over-flights may need to be more frequent than the every-9-d coverage now provided by the LandSat satellite systems, in order accurately to establish albedo trends before and after head ripening to determine the critical minimum albedo value required to estimate final grain yield.

Our present approach is intended for use only with grain crops, but might be extended to other types of crops. For two reasons, our data suggest that the linear relationship shown in Fig. 4 may be applicable to durum wheat (Produra) grown anywhere in the world. First, the low albedo values after the early rains that reduced soil albedo were not apparent beyond day 80, when all plots had developed green leaf area indices of 2.5 or more. Thus, beyond this stage of growth, soil albedo seems to be of no consequence. Second, there were significant differences in the numbers of heads produced by each plot, yet no explicit accounting for this fact was required by us in correlating albedo with final grain yield. Thus, density of planting may also prove to be of little consequence.

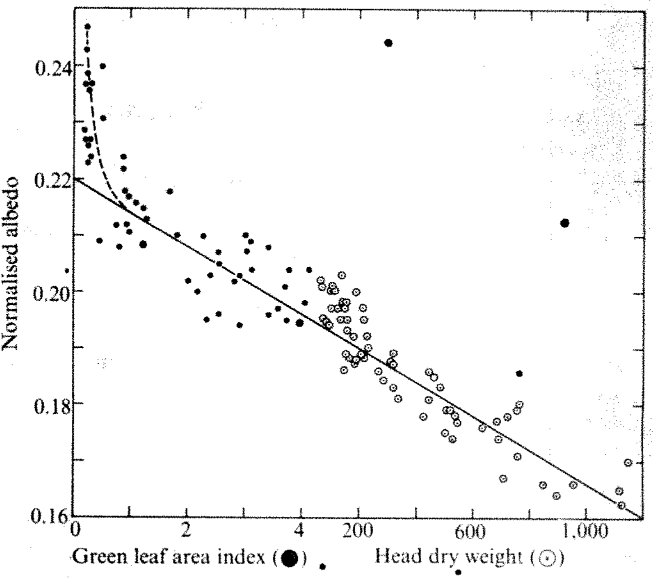

Fig. 3 Clear-day normalised albedo against green leaf area index and head dry weight of Produra wheat grown at Phoenix, Arizona.

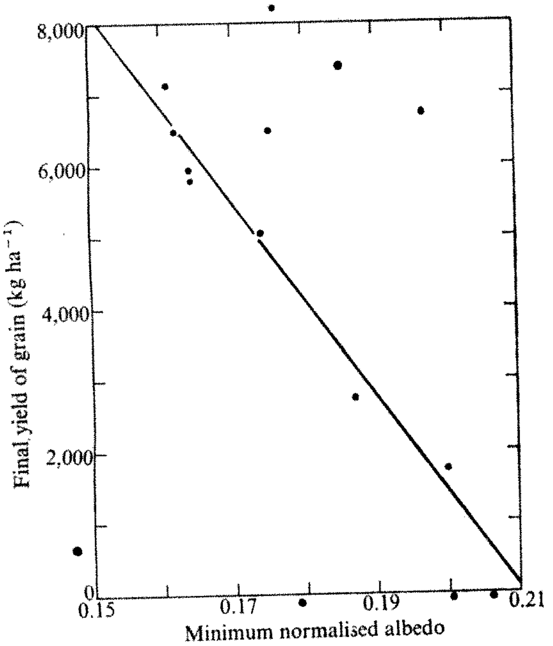

Fig. 4 Final grain yield of six differentially-irrigated plots of Produra wheat grown at Phoenix, Arizona against the minimum value of normalised albedo measured over each plot. $y = 28,370-134,700\,x$, $r_{y-x} = -0.986$.

Finally, we believe that measurement of reflected solar radiation is one viable means for the remote sensing of crop yields. Together with estimation techniques based on remote surface temperature measurement[3], it should make possible a remote sensing system for the evaluation of agricultural productivity on a global scale.

Experimental transmission of *Leishmania chagasi*, causative agent of neotropical visceral leishmaniasis, by the sandfly *Lutzomyia longipalpis*

The phlebotomine sandfly *Lutzomyia longipalpis* Lutz & Neiva (Diptera: Psychodidae) has long been suspected to be the vector of *Leishmania chagasi* Marques da Cunha & Chagas, in the principal foci of human visceral leishmaniasis ('kala azar') in Latin America[1]. In general, the distribution of this sandfly coincides with the human disease, and the insect is a common domestic or peridomestic species which feeds avidly on man. *Lu. longipalpis* has been found naturally infected with promastigote flagellates which could have been those of *L. chagasi*[2–3], but on none of these occasions was the parasite inoculated into susceptible laboratory animals and its true identity remains unknown. Previous attempts to experimentally transmit *L. chagasi* by the bite of *Lu. longipalpis* have failed[4]. We report here the first experimental transmissions of the parasite by laboratory-bred *Lu. longipalpis*, thus providing further evidence that this sandfly is a major vector of American visceral leishmaniasis.

In transmission experiments we used an isolate (L.d./PP-75) of *L. chagasi* obtained from a child from Ituaçu, Bahia State, Brazil. The parasite was passed from the original culture medium in which it was isolated, directly into hamsters: it had been passaged in these animals on only three occasions before the present experiments were commenced. It is a particularly virulent organism in the hamster, the animals usually dying of a fulminating infection in 5–7 months after the intraperitoneal inoculation of spleen suspension from infected animals.

Our closed colony of *Lu. longipalpis* was established from flies collected in houses and farm buildings in Morada Nova, Ceara State, north-east Brazil: at the time of this work it was in its twenty-third generation[5].

The infection rate obtained by feeding *Lu. longipalpis* on the skin of anaesthetised, infected hamsters was low (about 10%) and we felt that if successful transmission was to be achieved we needed much larger numbers of heavily infected sandflies than this method could provide. Following the findings of Adler and Theodor[6], one of us (R.D.W.) tried feeding *Lu. longipalpis* on defibrinated rabbit blood through a variety of membranes. It was found that large numbers would readily engorge, and that the most suitable membrane was freshly removed chick skin. Temperature of the blood was maintained at 37 °C by use of an immersion thermostat apparatus (Thermomix II). We felt, therefore, that by using this system with a suspension of amastigotes of *L. chagasi* in rabbit blood we could probably ensure that all fed sandflies were infected.

Hamsters with 5–6-month-old infections usually showed spleens that were packed with parasites. The spleen of one such animal was triturated in a glass tissue-grinder with 4.0 ml of sterile, defibrinated blood which had been inactivated at 56 °C for 20 min (Fig. 1*a*). Approximately 300 *Lu. longipalpis* were fully engorged on this suspension, through a chick membrane, and subsequently maintained in individual tubes[7].

Dissections of sandflies confirmed a 100% infection rate: by 5 d after the infective feed they were showing massive promastigote infections throughout the midgut and up to the anterior part of the cardia, where they appeared as stubby or rounded forms attached to the intestinal wall.

Each day, all those sandflies which had oviposited were released into a cage into which was placed a clean hamster, anaesthetised with Nembutal (Abbott). The animal was placed on its back and secured to a cork board with adhesive tape: its abdomen was shaved, to offer maximum surface area to the sandflies, and all re-feedings were carried out in the dark. Twelve transmission attempts were made, using batches of 4–40 infected flies. The first was on day 7 after the infective feed, and the rest on days 8–17 and 19.

Numerous flies were dissected during the experiment in order to follow the development of *L. chagasi*, and in particular to see when flagellates first gained entry to the pharynx and proboscis.

On day 5 of the infection the single fly examined showed enormous numbers of long thin promastigotes (Fig. 1*b*) in the midgut, with somewhat shorter, dividing forms in a more anterior position in the cardia (Fig. 1*c*). No parasites were seen in the pharynx, cibarium or proboscis. Two insects dissected on day 6 showed a similar pattern of development.

On day 7, one out of three *Lu. longipalpis* showed three promastigotes swimming freely in the pharynx. These parasites (Fig. 1*d*) were notably smaller than the form seen in the midgut of the same fly, and they moved with extraordinary rapidity. No parasites were seen in the proboscis of this insect, and the two other sandflies

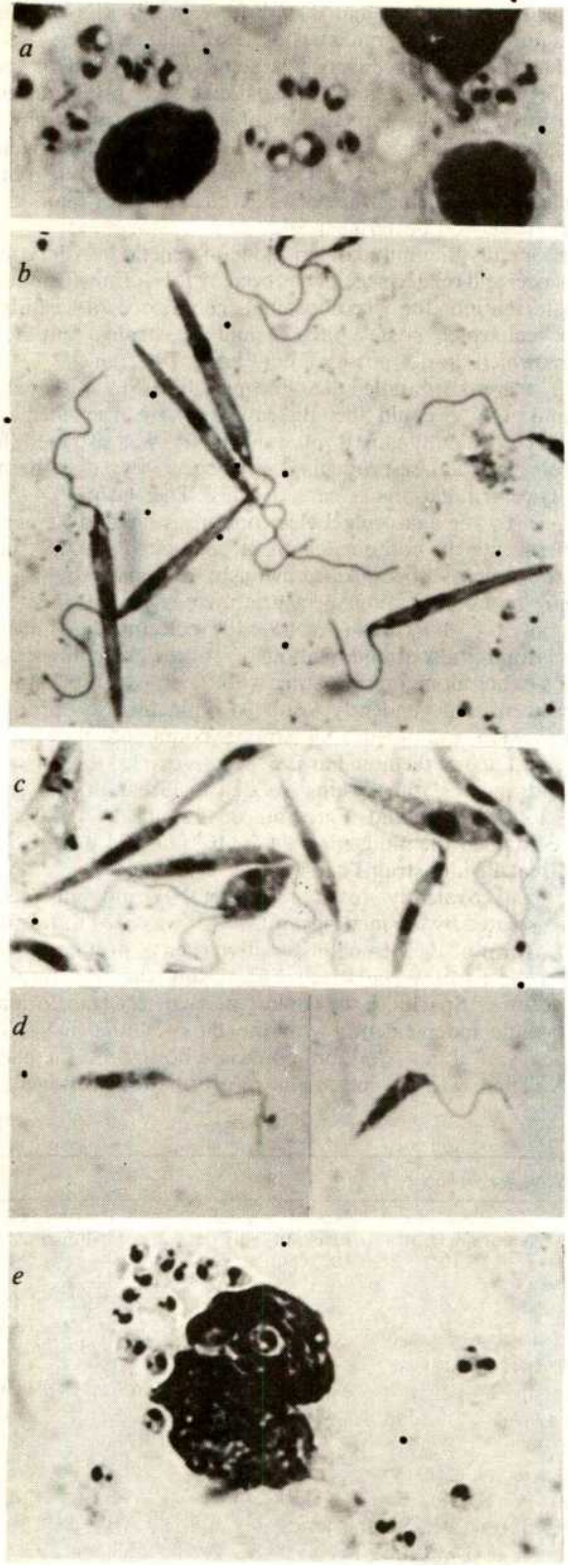

Fig. 1 Experimental transmission of *Leishmania chagasi* by the bite of the sandfly *Lutzomyia longipalpis*. *a*, Stained smear of a suspension of amastigotes of *L. chagasi* obtained by triturating the spleen of an infected hamster in inactivated rabbit blood. This material was used to infect the sandflies, through a chick-skin membrane. *b*, Long, thin promastigotes of *L. chagasi*, as seen in the midgut of *Lu. longipalpis*, 5 d after the infective feed. *c*, Shorter flagellates, some dividing, from the cardia of the same fly. *d*, Small promastigotes of *L. chagasi* from the pharynx of *Lu. longipalpis* on day 7 of infection. *e*, Impression smear of the spleen of a hamster, approximately 4 months after the animal was bitten by three infected *Lu. longipalpis*: intracellular and extracellular amastigotes of *L. chagasi*. All preparations fixed in absolute methyl alcohol and Giemsa-stained (×1,420).

dissected at the same time had flagellates no further forward than the cardia. On day 8, a single insect examined again showed a massive infection of the midgut, including the cardia, but absence of parasites in the foregut. Subsequently, pharyngeal forms were once more seen, in one fly, on day 10. Six others dissected during days 11–13 showed only midgut infections.

The first occasion on which flagellates were seen in the proboscis was on day 14, when two flies were dissected: both showed the usual, heavy midgut development of *L. chagasi* and, in addition, a number of shorter and more active forms in the pharynx. In one of the sandflies, however, a single parasite was seen moving rapidly up and down the length of the proboscis.

No foregut forms were seen in two insects examined on day 15, but light pharyngeal and proboscis infection was found in one sandfly on day 16. Finally, two flies dissected on day 17 showed parasites restricted to the midgut; no sandflies were examined beyond this date.

One hamster was found moribund, just over 4 months after three infected *Lu. longipalpis* had fed on it. Necropsy showed very large numbers of amastigotes of *L. chagasi* in impression smears of the spleen (Fig. 1*e*), and slightly fewer in the liver: culture of splenic tissues in blood–agar medium (NNN) produced growth of promastigotes. The remaining 11 hamsters were killed and examined at various dates from 5–6 months after the experiment, and four more proved to be infected: they showed variable numbers of amastigotes in the spleen, liver and bone marrow, and in all cases the spleen was the most heavily parasitised organ.

Thus at least 5 separate transmissions were achieved after feeding a total of 34 infected *Lu. longipalpis* on 12 hamsters. As up to six infected sandflies were on some occasions persuaded to feed on a single hamster, it is very likely that the number of transmissions was in fact more than five.

All transmissions were made during the first blood meal after the insects were infected, on days 7, 11, 13, 14 and 15. The transmission as early as 7 d after the infective meal is particularly interesting, for although scanty pharyngeal parasites were seen in one fly at this time no proboscis infections were recorded until the fourteenth day. Possibly the previous presence of flagellates in the proboscis is not prerequisite to transfer of the parasite, there simply being a surge of parasites forward from the pharynx, into the mouthparts, during the feeding process.

The incubation of the infection to a fatal stage in the hamster following transmission by the bite of the sandfly did not differ significantly from that obtained after the direct passage of amastigotes by syringe. This seems surprising, considering the very large number of amastigotes usually injected—with a triturate of hamster spleen, for example. It suggests that many more promastigotes may be inoculated by the sandfly vector than we have previously suspected.

We consider that the luxuriant growth of *L. chagasi* in *Lu. longipalpis*, the consistent migration of the parasite to the anterior station of the intestine and the biting mouthparts, the relative ease with which transmission was achieved by the bite of the insect, together with previous epidemiological evidence, confirm that *Lu. longipalpis* is a major vector of *L. chagasi* in endemic areas of human visceral leishmaniasis in Latin America. A detailed account of the morphological development of *L. chagasi* in *Lu. longipalpis* will be published elsewhere.

This work was supported by the Wellcome Trust and the Instituto Evandro Chagas of the Fundaçâo Serviços de Saúde Pública (F. SESP) of Brazil. We thank Roberto Naiff, Maricleide Farias, Cristina Loureiro, Cesarina Arcanjo and José Almeida for technical assistance. Aluízio

Figueiredo was responsible for photography. Dr Robert Sogayar provided the *L. chagasi* isolate.

Conjugal transfer of R plasmids in *Neisseria gonorrhoeae*

THE appearance of penicillin-resistant, β-lactamase-producing strains of *Neisseria gonorrhoeae* has been the cause of considerable concern[1]. We have recently shown that β-lactamase production by these gonococci is plasmid mediated[2]. Two distinct R plasmids have been characterised; one, with mass 4.4×10^6 was common in gonococci isolated from military personnel in the Far East and their sexual contacts. The other plasmid with mass 3.2×10^6 was found in a strain isolated from a woman in London[3] and we have also found this plasmid species in clinical isolates from Liverpool[4]. DNA–DNA duplex studies have revealed that both gonococcal R plasmids posses a significant portion (about 40%) of the transposable sequence, TnA, which includes the β-lactamase gene commonly found on R plasmids of the Enterobacteriaceae, *Pseudomonas aeruginosa* and *Haemophilus influenzae*[2].

While studying the β-lactamase producing gonococci from the Far East we noted that they differed in nutritional requirements and in chromosomal antibiotic resistance genes, suggesting that there had been considerable dissemination of the R plasmid rather than simply the spread of a single ancestral clone. Investigations into the possible modes of dissemination led us to discover that a 24.5×10^6 molecular mass indigenous plasmid possessing sex factor activity seems to play a significant part in the transfer of R plasmids from gonocci to other strains and bacterial species.

Historically, the only known mode of genetic transfer among gonococci and related species has been by DNA transformation[5]. Transformation for chromosomal genes occurs readily to gonococci which posses pili (T1 and T2 strains) but not to strains which do not possess pili (T3 and T4 strains)[6].

We, therefore, studied first the possibility that gonococcal plasmid DNA could be disseminated by transformation. Purified covalently-closed plasmid DNA was isolated from several β-lactamase-producing gonococci by dye buoyant density centrifugation of cleared lysates[7]. The plasmid DNA was analysed by the agarose gel electrophoresis method[8] as well as by measuring the contour length of open circular DNA in the electron microscope[2]. As previously described by us and others[10] gonococci almost invariably possess an indigenous plasmid 2.6×10^6 in mass. A 24.5×10^6 molecular mass indigenous plasmid is also found in about 5% of the penicillin-sensitive strains either alone or coexisting with the 2.6×10^6 plasmid[9].

Thirteen independently isolated β-lactamase producing strains were examined. All strains contained the 2.6×10^6 plasmid. Each of the nine Far East strains carried the 4.4×10^6 R plasmid and the four strains isolated in Great Britain carried the 3.2×10^6 R plasmid. Three out of the nine Far East strains also contained the indigenous 24.5×10^6 plasmid while none of the Great Britain strains carried it.

Purified covalently-closed plasmid DNA and bulk cellular DNA isolated by the methods of Catlin[11] was used to transform the T1 form of the penicillin-sensitive (Pen^s), proline requiring (Pro$^-$) *N. gonorrhoeae* strain F62. Using the transformation procedure of Sparling[5], we could readily detect transformation for proline independence with the bulk cellular DNA (at a frequency of about 1%)[5], but could not do so with the plasmid DNA. There was no detectable transformation to β-lactamase

Table 1 R plasmid transfer by *N. gonorrhoeae*

Donor strain†	Plasmid complement ($\times 10^6$)	Recipient strains	Plasmid complement ($\times 10^6$)	No. of penicillin-resistant cells per 10^8 recipient cells	Property of penicillin-resistant cells

Equal volumes of donor and recipient cells (1×10^7 colony forming units of each) were mixed in 10 ml of modified GC broth[9] supplemented with 2×10^{-3} M $CaCl_2$ and 2×10^{-3} M $MgCl_2$. After overnight incubation the cells were collected by passing 3 ml of the culture through a membrane filter (Biorad 0.2 µm). The filter was then placed on plates of double-strength Kellogg's medium[9] and incubated for 6 h. The filters were removed and placed in 2 ml of GC broth and vigorously agitated to remove the cells. Samples of the mating mixture were plated on Kellogg's medium supplemented with 1 µg ml^{-1} penicillin G and 1 µg ml^{-1} nalidixic acid or 1 µg ml^{-1} penicillin G and 1 µg ml^{-1} rifampicin. Colonies appearing on the selective media were restreaked five times on the same selective media, and tested for β-lactamase activity using a chromogenic cephalosporin substrate[3]. The plasmid component of representative colonies showing β-lactamase activity was determined by Agarose gel electrophoresis.

Similar mating experiments were performed with *E. coli* HB101 as recipient and β-lactamase-producing recipients were selected by plating on MacConkey's agar containing 30 µg ml^{-1} ampicillin. In some experiments, 50 µg ml^{-1} of DNase (pancreatic DNase, Worthington) was added to the broth medium at the time of cell mixing, readded just before filtration, and added once again when the cells were removed from the filter.

*The data presented is from one set of experiments. In three later matings a range of 10^3 to 10^4 penicillin-resistant cells per 10^8 recipients were found in the CDC67–F62 matings.

†T4 colony type, see text: *pro*$^-$, proline required; *arg*$^-$, arginine required; Pen^r, penicillin resistant; Pen^s, penicillin sensitive; *rif*^{r}, rifampicin resistant; *nal*^{r}, nalidixic acid resistant; Amp^s, ampicillin sensitive.

production with either the cellular or plasmid DNA preparation. A number of other gonococcal recipients were then used, including a strain devoid of any plasmid species. None was transformed for β-lactamase production. In contrast, *E. coli* K-12 recipients were transformed to ampicillin resistance at a frequency of about 10^3 cells per microgram of purified plasmid DNA, and were found to possess only a single R plasmid. We concluded, therefore, that the gonococci were refractory to transformation by closed circular plasmid DNA and the mechanism for the dissemination of the gonococcal R plasmids was not likely to be transformation.

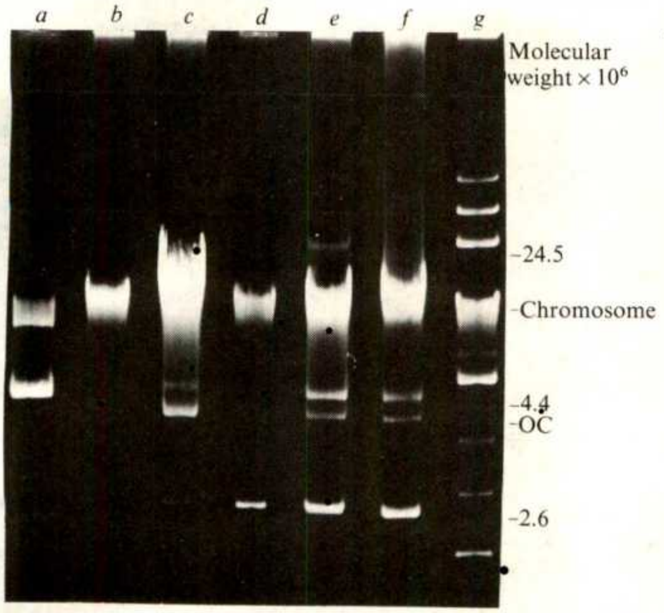

Fig. 1 Agarose gel electrophoresis of ethanol-precipitated DNA from cleared lysates of donor, recipient and penicillin-resistant recipient strains of *N. gonorrhoeae* and *E. coli*. *a*, Strain of *E. coli* HB101 penicillin-resistant recipient containing the 4.4×10^6 dalton plasmid derived from parental strain in slot *b*. Occasionally in the *E. coli* penicillin-resistant recipient lysates a plasmid band appears above the chromosome on the Agarose gel (not seen in this picture). The unusual band has been identified as an oligomer of the 4.4×10^6 plasmid by restriction enzyme analysis. *b*, Ampicillin-sensitive recipient strain of *E. coli* HB101 containing no plasmids. *c*, Ampicillin-resistant recipient containing the 4.4×10^6 dalton plasmid and the 2.6×10^6 cryptic plasmid, derived from parental strain in slot *d*. *d*, Penicillin-sensitive recipient strain of *N. gonorrhoeae* F62 containing the 2.6×10^6 cryptic plasmid. *e*, Penicillin-resistant donor strain *N. gonorrhoeae* CDC 67 containing the 24.5×10^6, 2.6×10^6 indigenous plasmids and the 4.4×10^6 R plasmid. *f*, Penicillin-resistant donor strain of *N. gonorrhoeae* CDC36N containing the 2.6×10^6 indigenous plasmid and the 4.4×10^6 R plasmid. *g*, Standard plasmid DNAs; ranging in size from 62×10^6 (uppermost band) to 1.9×10^6 (lowest band). OC refers to the open circular form of the 2.6×10^6 cryptic plasmid.

The relatively high incidence of the 24.5×10^6 indigenous plasmid among the β-lactamase producing strains suggested the possibility that this plasmid might possess sex factor activity and that R plasmid transmission between gonococci might be mediated by conjugation. Donor and recipient strains exhibiting the non-piliated T4 colonial morphology were isolated. The donor strains were all β-lactamase producers and either required arginine (Arg$^-$) or required no added amino acids to grow on Catlin's defined medium[11]. The donor strains were sensitive to 1 μg ml^{-1} of nalidixic acid (Nal) and/or 1 μg ml^{-1} of rifampicin (Rif). The recipient strain used was the T4 form of the strain F62 (Pro$^-$ Rif^r Nal^r). Matings were performed by a variation of the filter method used by Van Klingeren *et al.* to examine the conjugative properties of *H. influenzae* R plasmids[12]. Similar mating experiments were also performed using *E. coli.* strain HB101 (ref. 7) as a recipient.

The results of several representative mating experiments are summarised in Table 1. Plasmid complements of donor and recipient cells as well as resistant cells recovered from mating mixtures are illustrated in Fig. 1. β-lactamase-producing *N. gonorrhoeae* and *E. coli* recipient cells were recovered in the matings. However, successful transfer of the R plasmid was observed only when the donor gonococcal strain possessed the 24.5×10^6 plasmid as well as the R plasmid. No β-lactamase-producing recipients could therefore be isolated from matings in which isolates from Great Britain were used as donors nor with donor strains of Far East origin which lacked the 24.5×10^6 plasmid. As shown in Fig. 1, the acquisition of β-lactamase biosynthesis by recipients was associated with the appearance of R plasmid DNA. The selection of β-lactamase-producing gonococci or *E. coli* recipients was not influenced by the presence of DNse (data not shown).

The data suggests that the indigenous 24.5×10^6 plasmid plays a significant part in the transfer of R plasmids from gonococci to other strains and species. We hypothesise that this large cryptic plasmid possesses sex factor activity and is able to mobilise or otherwise promote the transfer of the smaller coexisting R plasmid by conjugation. It seems improbable that transformation is involved in the transfer of R plasmids in mixed culture because of the failure to demonstrate the phenomenon with purified plasmid DNA, because the T4 donor and recipient cells are not normally competent for DNA transformation[5], and because plasmid transfer in mixed cultures was uninfluenced by DNse. Phage-mediated transduction could be an alternative explanation for our results, although to our knowledge no gonococcal phage has been described and any transducing phage would have to have the unusual ability to infect both *E. coli* and *Neisseria*. Moreover, cell-free filtrates of the donor strains could not transfer the R plasmid to *N. gonorrhoeae* or *E. coli* recipient cells (data not shown).

It thus seems likely that conjugation is the mechanism of R plasmid transfer in the gonococci and is promoted by the 24.5×10^6 plasmid. In overnight matings the 24.5×10^6 plasmid and 2.6×10^6 plasmid are often also detected in *Neisseria* but not *E. coli* which received the R plasmid. Recent data has shown that the 24.5×10^6 plasmid is capable also of promoting the transfer of chromosomal genes. The finding that R plasmids of *N. gonorrhoeae* seem to be readily transmitted among various strains of gonococci has serious epidemiological implications. Not only must we be concerned about the possibility of widespread dissemination of resistance but also the extension of resistance to related microorganisms such as *N. meningitidis* which are currently penicillin sensitive. We feel this change is required in light of new data which has shown that in overnight mating significant numbers of gonococcal recipients received the 24.5 MDal plasmid and thus are capable of transmitting the R plasmid to new strains. This has very serious epidemiological consequences.

We thank Dr C. Thornsberry, Center for Disease Control, Atlanta, Georgia for providing us with the penicillin-resistant strains of *N. gonorrhoeae*, and Dr Lynn Elwell and Dr Leonard Mayer for help and suggestions. This work was supported by a grant from the National Institutes of Allergy and Infectious Diseases.

Thymus metabolises progesterone—possible enzymatic marker for T lymphocytes

FEMALES of the athymic mutant strain of nude mice show severe deficiencies in reproductive function. The ovaries and the uterus are abnormally small[1], puberty is delayed[2], oestrous cycles are abnormal and mature females are usually sterile[1,3]. These abnormalities can be prevented by grafting thymic tissue at birth[2,3]. Similar abnormalities result from neonatal thymectomy of normal female mice, and can be corrected by thymus re-grafting up to 7 d age[2,4]. These observations suggest an involvement of the thymus in gonadal development and function. Conversely, certain sex hormones are known to cause atrophy of the thymus[5]. Hitherto, however, there has been no evidence implicating the thymus of the infantile mouse in sex hormone metabolism. We report here the presence of 20α-hydroxysteroid dehydrogenase (20α-SDH) activity in the mouse thymus, an enzyme engaged in progesterone metabolism.

Thymus glands of 10-d-old C57BL female mice were homogenised in 0.01 M sodium phosphate, *p*H 7.4, 0.25 M sucrose and 0.001 M $MgCl_2$ and incubated at 37 °C with 1,2,6,7-^3H-progesterone 1×10^5 d.p.m. (specific activity 100 Ci mmol^{-1}, New England Nuclear) and varying amounts of unlabelled progesterone in the presence of 1 mM NADPH and 10 mM glucose-6-phosphate. After 5–60 min of incubation the resulting steroids were extracted with diethyl ether and separated by thin-layer chromatography in the system ether–chloroform (3:10), where the substrate is separated from reduced metabolites of progesterone. Radioactive zones were located on the plates by scanning with a gas-flow counter (Packard model 7201) and the radioactive compounds were scraped off the plates, eluted with methanol and counted in a Packard TriCarb Scintillation counter.

Radiolabelled progesterone was converted to a radioactive product with chromatographic mobility ($R_f = 0.33$) identical to that of 20α-hydroxypregn-4-en-3-one (20α-OHP) and distinct from the residual substrate ($R_f = 0.66$). The compound did not dissociate from carrier 20α-OHP when cochromatographed in two additional systems, benzene–acetone (4:1; $R_f = 0.4$) and cyclohexane–ethyl acetate (1:1; $R_f = 0.46$). A mixture of the TLC-purified radioactive product (92,000 d.p.m.) and authentic 20α-OHP (31.5 mg; Ikapharm) was recrystallised thrice from aqueous methanol, yielding crystals of constant specific activity (2610 ± 130 d.p.m. mg; mean ± s.e.m.), and the specific activity of the second and third crops of crystals did not differ significantly from the corresponding mother liquors. These results indicate that the progesterone metabolite formed by the thymus tissue was 20α-OHP.

The thymic enzyme catalyses the reaction in both directions: incubation of thymus homogenate with 20α-OHP in the presence of NADP resulted in the production of progesterone (data not shown). When 20α-OHP was incubated with thymus homogenate for 2 h in the presence of NADPH, no additional metabolites were detected.

Activity of thymic 20α-SDH was linear up to 30-min incubation at 37 °C (Fig. 1*a*), and was directly proportional to protein concentration (measured by the method of Lowry *et al.*[6]), up to 600 μg ml^{-1} (Fig. 1*b*). The apparent K_m of the thymic 20α-SDH was 21.6 ± 3.3 μM (Fig. 1*c*), which is close to the value reported for the ovarian 20α-SDH (ref. 7). The V_{max} of the thymic enzyme for the reductive step was 10.0 ± 0.4 nmol 20α-OHP per mg protein per 20 min.

A comparison of 20α-SDH activity in various organs of immature mice (Table 1) shows that enzyme activity of the thymocytes is at least 16-fold higher than in lung or kidney tissue. The thymocytes seem to be the source of the thymic enzyme, as their specific activity is approximately twice that of the whole gland. Considerable enzyme activity is present in the spleen of normal C57BL mice, but is almost absent in the spleen of athymic (nude) mice (Table 1). These results suggest that 20α-SDH is associated with thymus-processed T lymphocytes, and not with B lymphocytes. To clarify this point, the ability of thymocytes and spleen cells from phenotypically normal heterozygous (nu/+ C57BL) to reduce progesterone was compared to that of spleen cells from athymic (nu/nu) mice of the same age (6-week-old). The red blood cells were selectively lysed by treatment with 0.83 NH_4Cl and the remaining white cells were washed with phosphate-buffered saline, collected by centrifugation at 500*g* (10 min) and resuspended in RPMI1640 containing 1.0 μM of labelled progesterone (400,000 d.p.m.).

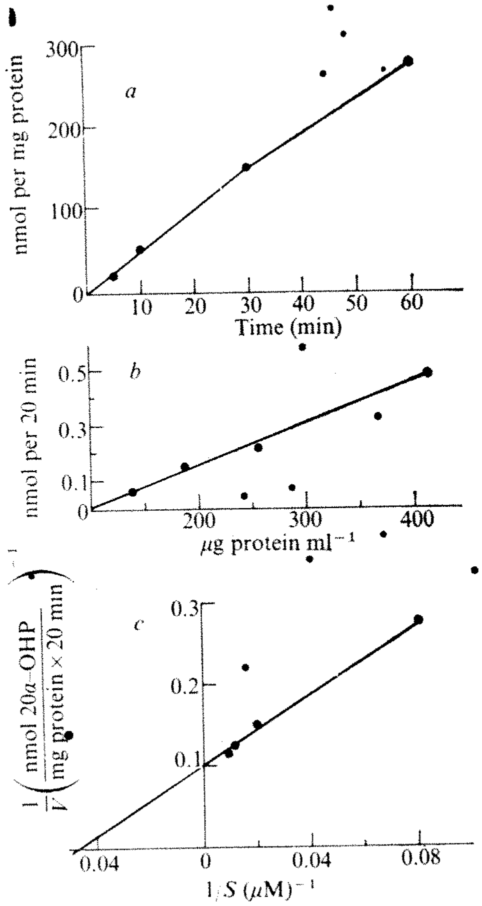

Fig. 1 Kinetic properties of thymic 20α-hydroxysteroid dehydrogenase. The enzyme in homogenates of thymus glands from 10-d-old mice was assayed as described in the text, except that in *a* and *b* cold progesterone, 25μM, was used as substrate. *a*, Time course of enzyme activity (470 μg protein per ml). Each point represents the mean of duplicate determinations. *b*, Effect of enzyme concentration on the rate of conversion of progesterone to 20α-dihydroprogesterone. *c*, Double reciprocal plot of results according to the Lineweaver–Burk method. The apparent K_m was estimated according to Wilkinson[14]. The K_m was 21.6 ± 3.3 and V_{max} 10.0 ± 0.4 nmol 20α-OHP per mg protein per 20 min.

Table 1 Distribution of 20α-hydroxysteroid dehydrogenase

Organ	Specific activity (nmol 20α-OHP produced per mg protein per h)
Thymus	4.39
Thymocytes	9.87
Spleen	0.25
Spleen of athymic mouse*	0.03
Lung	0.61
Kidney	0.29

Thymus and other organs from 10-d-old female C57BL (nu/+) mice were assayed for 20α-SDH activity as described in Fig. 1 legend. The homogenates were incubated for 60 min.

* Athymic nude C57BL (nu/nu) mouse and the phenotypically normal heterozygous C57BL (nu/+) were obtained from G. L. Bomholtgaard, Denmark.

DEAE-Sepharose® CL-6B
CM-Sepharose® CL-6B

Macroporous, bead-formed ion exchangers based on the new high-stability, cross-linked agarose matrix, Sepharose CL

- High resolution and capacity for high molecular weight proteins and other biopolymers
- Exceptionally stable bed volume. Excellent flow rates
- Can be used in polar organic solvents and in solutions of non-ionic detergents
- Can be sterilized repeatedly by autoclaving
- Rapid equilibration. No precycling

The Science Dictionaries

Three useful and up-to-date works of reference intended not only for students, teachers and researchers but also for science journalists and the general reader.
Each book is designed for easy use – entries are arranged alphabetically and defined under the most common form of term, with synonyms in brackets. S.I. units are used throughout and all entries are thoroughly cross-referenced.

A Dictionary of Life Sciences

E. A. Martin

The recent trend to treat the biological/life sciences as a whole rather than divided into separate units is reflected in this concise dictionary which brings together in one volume all the main branches of zoology and botany. Selected terms in related fields of biochemistry, endocrinology, animal behaviour and palaeontology are also included. All major plant and animal classes are fully described as well as the more important orders, and common names of animals and plants are cross-referenced to their appropriate taxonomic groups.
1976 £5.95 392pp

A Dictionary of Earth Sciences

Stella E. Stiegeler

The subjects covered here include geophysics, structural geology, geomorphology, oceanography, stratigraphy, palaeontology, sedimentology, climatology, meteorology, soli science, cartography, mineralogy, petrology and surveying. The terms defined reflect the recent modification of traditional concepts and the resulting development of terminology in the earth sciences. In soil science, for example, a new system of classification is now in in use, with a completely new terminology for the soil orders.
1976 £5.95 320pp

A Dictionary of Physical Sciences

John Daintith

This book covers the main branches of physics, chemistry and astromony – from Abbe condenser to zoom lens and zwitterion. A selection of relevant terms from the related fields of electronics, computer science and mathematics is included. Full accounts are given of the properties and uses of the chemical elements and many of their compounds. All the chemical terminology used is that recommended by the International Union of Pure and Applied Chemistry.
1976 £5.95 352pp

The rate of 20α-OHP accumulation ((pmol h^{-1} per 5×10^6 cells) during a 1-h incubation at 37 °C determined as described before, was 335.0 for thymocytes, 105.0 for spleen cells from nu/+ mice and <5.0 for spleen cells from athymic nu/nu mice. The results indicate that in lymphocytes the enzyme is only represented in the T-cell type.

It has been reported that thymic tissue and lymphocytes are capable of reversibly oxidising cortisol to cortisone[8], and that the activity of the enzyme that catalyses this oxidoreduction (11β-hydroxysteroid dehydrogenase) was 0.128 nmol per 100 mg tissue per 3 h incubation, which is $<1/1000$ of the activity of 20α-SDH reported here. 20α-SDH occurs in ovaries of many species and particularly in regressing corpora lutea of rodents, where its appearance signals the onset of luteolysis[9,10]. To our knowledge, no other enzyme activity connected with sex steroid metabolism has been reported to operate in the thymus.

During the incubation of radiolabelled progesterone with thymocytes we were able to detect a small amount of 5α-reductase activity, an enzyme which reduces progesterone to its 5α-pregnane derivative. The major pregnane product formed was identified as 5α-pregnane-3,20-dione by chromatography in 3 TLC systems, and by gas-chromatographic analysis of its *bis*-thioketal derivative[11]. In addition, the partially purified product was recrystallised with authentic 5α-pregnane-3,20-dione (Ikapharm) to constant specific activity.

The significance of the two progesterone metabolising enzyme activities in the thymus is not clear. Progesterone has been reported to be immunosuppressive[12,13] at high concentrations, which are achieved, probably, only near its site of formation in the foeto-placental unit. It is therefore conceivable that an enzyme engaged in reducing progesterone may have a role in the defence mechanisms mediated by thymocytes. Experiments are in progress to relate the distribution of 20α-SDH to that of known T-cell markers, such as θ antigen and responsiveness to plant lectins.

Evidence for control of complement receptor rosette-forming cells by α- and β-adrenergic agents

PHARMACOLOGICAL agents such as dibutyryl cyclic AMP[1,2], cholera toxin[3,4] and β-adrenergic stimulants[5] have an effect on antibody production which can be inhibitory or enhancing, depending on the dose used and the time of addition of the agent. Such stimulants are known to inhibit the human T-lymphocyte receptor for sheep erythrocytes[6,7] and the murine lymphoma Fc receptor[8], and it has been shown that the complement receptor on B lymphocytes has an important role in the cellular events leading to antibody production[9,10], thus emphasising the need to clarify its nature. We report here that the number of complement receptor rosette-forming cells (EAC–RFC) in suspensions of mouse spleen cells can be decreased by α-adrenergic stimulants and increased by β-adrenergic stimulants, respectively.

Male CBA mice, of 3–5 months, were killed by ether inhalation. The spleens were teased in Eagle's minimal essential medium (MEM) to give a single cell suspension. The cells were washed twice and the concentration adjusted to 5×10^6 ml^{-1} in Eagle's MEM containing 10% heat-inactivated foetal calf serum incorporating various concentrations of the pharmacological agents under study. After 3-h incubation at 37 °C in a humid atmosphere containing 5% CO_2 in air, the cells were washed three times and 5×10^6 cells finally resuspended in 0.5 ml Eagle's MEM. The cell viability was judged to be 90–93% by the eosin dye exclusion test. For the estimation of complement rosettes, 0.5 ml aliquots of a 1% suspension of sheep red blood cells which had been freshly coated with rabbit anti-sheep red blood cell haemolysin (1: 1,000) and fresh mouse serum (1 : 20) as a source of complement, were centrifuged with an equal volume of the lymphocyte suspension at 200*g* for 2 min. The cell pellets were incubated together at 37 °C for 15 min, resuspended, and the number of rosette-forming cells counted. A rosette-forming cell was defined as a white cell with three or more adherent erythrocytes. Each study was done in duplicate and 400 cells were counted per tube. To identify the type of cells involved in the rosettes, 10 mM EDTA was added at the time of the rosette assays[11]. No significant change was observed. The rosette-forming cells in cultures of spleen cell suspensions incubated for 3 h with isoproterenol, adrenaline, noradrenaline, propranolol, dibutyryl cyclic AMP, dibutyryl cyclic GMP, aminophylline (all Sigma) or phentolamine (Regitin, CTBA) were therefore thought to be lymphocytes.

The effect on EAC–RFC of the β-adrenergic stimulator, isoproterenol, is shown in Fig. 1*a*. The number of EAC–RFC rose to a peak in a concentration of 5×10^{-5} M isoproterenol, and declined to almost to control values at 10^{-14} M. Isoproterenol is known to increase the concentration of intracellular cyclic AMP by stimulating adenyl cyclase activity[12]. The addition of dibutyryl cyclic AMP, however, had no effect on the number of EAC–RFC (Fig. 1*h*). When 10^{-4} M aminophylline, a phosphodiesterase inhibitor[13], was added with dibutyryl cyclic AMP, the number of EAC–RFC was unchanged (Table 1). The α-stimulant noradrenaline inhibited slightly the number of EAC–RFC. Adrenaline, which is thought to stimulate both the α- and β-adrenergic receptors, had no effect on the number of EAC–RFC (Fig. 1*e*). Presumably the effect of stimulating both receptors at the same time is to cancel out any effect on the number of EAC–RFC. It can be demonstrated, however, that adrenaline in such a situation is active, since its addition simultaneously with 10^{-5} M phentolamine (an α-blocker)[14] or 10^{-5} M propranolol (a β-blocker)[15] results in a significant increase or decrease, respectively, in the number of EAC–RFC (Fig. 1*f*,*g*). The concentrations of propranolol and phentolamine were such that neither drug on its own had a significant effect on EAC–RFC. It is probable that normal foetal calf serum contains a small quantity of adrenalines. Therefore the following experiment was done to clarify the effect of α-stimulant (noradrenaline) or β-stimulant (isoproterenol) in the foetal calf serum culture medium. When 10^{-5} M phentolamine was added to the medium containing isoproterenol, EAC–RFC increased in number as far as the concentration of the latter was

†$P < 0.001$.
‡$P < 0.005$.
Statistical treatments were done with the difference between the mean value of rosette-forming cells of the test group and that of the control group.

kept between 10^{-11} M and 10^{-15} M (Fig. 1*b*). When 10^{-5} M propranolol was added to the medium in the presence of 10^{-4} M to 10^{-10} M noradrenaline, EAC–RFC decreased in number (Fig. 1*d*). Dibutyryl cyclic GMP seemed to have no effect on EAC–RFC (Fig. 1*i*).

Our results show that the number of EAC–RFC in a suspension of mouse spleen cells can be increased by the addition of a drug which stimulates the β-adrenergic receptor. Conversely, an agent which stimulates the α-receptor depresses the number of EAC–RFC. Further confirmation of these findings has been obtained from results which have shown that adrenaline (a stimulator of both α- and β-receptors) has no effect on the number of EAC–RFC in its own, but, with an α-blocker, adrenaline mimics a β-stimulator; when adrenaline and a β-blocker were used, the effect on the number of EAC–RFC is the same as that of an α-receptor stimulator (Fig. 1*f* and *g*).

α- and β-adrenergic receptors are thought to be regulatory (or receptor) units of the adenyl cyclase[16]. Activation of the β-receptor stimulates the enzyme and causes an increase in the level of intracellular cyclic AMP, whilst stimulation of the α-receptor causes a decrease in intracellular cyclic AMP.

We were, however, unable to demonstrate an effect on

complement receptor rosettes of dibutyryl cyclic AMP, an agent believed to act beyond the level of adenyl cyclase. Furthermore, there was no effect when dibutyryl cyclic AMP was added with aminophylline, an inhibitor of phosphodiesterase, which suppresses the breakdown of intracellular cyclic AMP and thus effectively increases its intracellular concentration[13]. The rosette-forming cells, therefore, seem to be affected, not by the increase in the intracellular cyclic AMP levels, but by the increase in adenyl cyclase activity itself. It is known that B lymphocytes with complement receptor can produce antibody to T-dependent antigens[9,10]. On the other hand, catecholamines (adrenaline and noradrenaline) enter the blood stream, circulate throughout the body and affect various organs as hormones. We therefore suggest that in the immune system catecholamines influence the activity of complement receptor of B-lymphocyte, resulting in control of antibody formation.

Response of mesencephalic and hypothalamic dopamine neurones to α-MSH: mediated by area postrema?

α-MELANOTROPIN (α-MSH) influences mammalian behaviour in a variety of situations. It is released from the pars intermedia of the pituitary during stress and may have a physiological role in adaptive processes[1,2]. In mammals, dopaminergic (DA) fibres of the tubero-hypophyseal system which originate in the arcuate nucleus of the hypothalamus, innervate the pars intermedia[3]; MSH secretion is usually inhibited by DA[4]. In rats, this DA system is subject to the influence of various extrahypothalamic brain regions thought to participate in the integration of endocrine and behavioural processes[5,6]. The tubero-hypophyseal DA neurones may therefore occupy a key position between brain areas involved in effects of behaviourally active peptide hormones on one hand and the pars intermedia, a site of production of such peptides, on the other hand. We report here that systemic injections of α-MSH in female rats affect the arcuate DA neurones as well as those of substantia nigra. The latter were studied in order to check for eventual parallel responses in an extrahypothalamic DA system. The peptide effect seems to depend upon the integrity of projections ascending from the lower brainstem. Cholinergic systems seem to participate in its manifestation.

We studied female SIV (Sprague–Dawley–Ivanovas) rats kept in groups of littermates under controlled illumination and temperature conditions (lights on 06.00–20.00; 22±1 °C). The animals were ovariectomised at the age of 4–5 months, 3 weeks before the experiments, and pretreated for one day with oestradiol-dipropionate (5 μg s.c.) and progesterone (2 mg s.c.), since we had used the same animal model in our studies on extrahypothalamic influences. The functional state of the DA neurone groups was assessed by a microfluorimetric procedure based on the histochemical fluorescence method of Falck and Hillarp. The distributions of fluorescence intensity of individual neurones are characteristic for a given functional state and neurone group. Studies on nigral DA neurones have revealed a close relation between mean intensity and mean firing rate; in agreement with earlier observations, a rise in mean intensity accompanied an increase in mean firing rate[7].

In the higher dose range which corresponds to that used in most behavioural experiments, α-MSH injected intraperitoneally (i.p.) (between 15.00 and 17.00) induced a marked rise in the mean fluorescence intensity of both DA neurone groups within 30 min (Fig. 1*a*, $P < 0.01$ for 100 μg per kg body weight; similar effect for 33 μg per kg but significant only in the arcuate nucleus). At lower doses, only the arcuate DA neurones responded ($P < 0.01$). This difference may have resulted from different sensitivities of the projection systems involved. The observation of a response of nigral DA neurones 15 min after injection of a lower dose in one rat suggests that the nigral reaction might also be more transient. If the relation established between cellular fluorescence intensity and neuronal activity[7] holds true also in the present case, the reaction of the arcuate DA neurones indicates an activation. Since DA inhibits MSH release[4], this corresponds to the activation of a negative feedback mechanism. The similar response of the nigral DA neurones may be linked with certain extrahypothalamic effects of the peptide. In analogy to the situation in the arcuate DA neurones, one may ask whether the nigral reaction might likewise reflect the activation of a compensatory mechanism. An aggravation of tremor by MSH has been noted in Parkinson patients[8]. Our findings are at variance with observations on repeated injections of α-MSH in male rats, where DA turnover in midbrain and striatum remained unchanged[9]. Whether this discrepancy is due to differences in the experimental arrangement or in the methods used for analysis of DA systems, cannot yet be decided. It seems conceivable that the hormonal state of the animal might influence peptide effects either qualitatively or quantitatively.

The response of the arcuate DA neurones cannot be expected to be specific for α-MSH, since this neurone group seems to be involved in the control of various pituitary hormones. Prolactin (secretion of which is likewise inhibited by this DA system) showed a similar effect (Fig. 1*b*, $P < 0.01$ compared with solvent- and to saline-injected groups). It can also be regarded as the activation of a negative feedback mechanism[10]. More surprising is the response of the nigral DA neurones ($P < 0.01$ versus solvent group, $P < 0.05$ versus saline group). It may reflect a direct effect of prolactin or be due to some more complex neuroendocrine mechanism. In contrast to what might have been expected in view of similarities between ACTH and MSH in some behavioural situations[1], comparable doses of $ACTH_{1-24}$ did not yield a clear-cut effect, but just a weak nigral reaction in half of the rats (Fig. 1*b*). The failure of $ACTH_{1-24}$ to affect the arcuate DA neurones is in keeping with the view that the DA system may be less important than noradrenergic neurones in the control of this hormone[11]. But changes in tubero-infundibular DA neurones have been

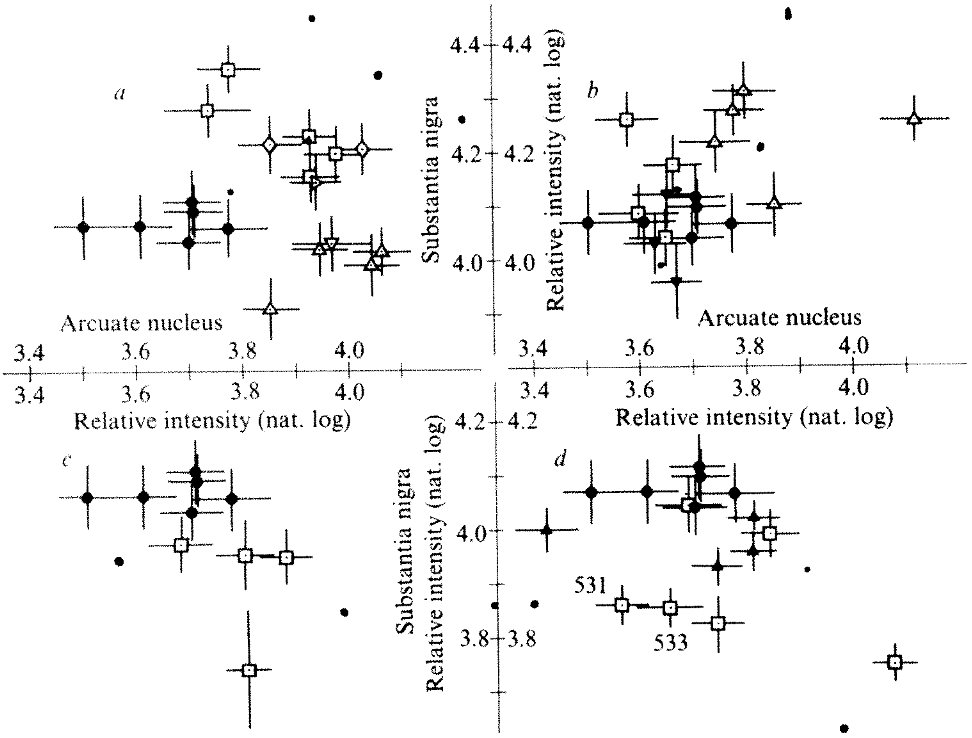

Fig. 1 Mean fluorescence intensity (bars = 95% confidence limits) of the DA neurone groups in the arcuate nucleus of the hypothalamus (abscissa) and in substantia nigra (ordinate) of individual rats. The saline-injected control group is shown for reference on each figure. *a*, Intensity 30 min (1 rat 15 min) after i.p. injection of α-MSH (Hoechst; dissolved in saline immediately before use, injection volume 0.1–0.2 ml per 100 g body wt.) at doses of (μg kg^{-1}) 100 (□), 33 (◇), 10 (△), 3 (▽), 10 (15 min; ▷) or saline (●). *b*, Effect of ovine prolactin 2mg per kg (Ferring; 1 mg per 0.25 ml solvent containing 1 mg phenol in 1 ml H_2O) (△) or $ACTH_{1-24}$ 175 μg per kg (Synacthen, CIBA; 0.25 mg ml^{-1}) (□) administered i.p. Doses are approximately equimolar to the highest dose of α-MSH used. Saline shown as (●); the phenol solvent itself remained without effect (▼). *c*, Blockade of the intensity change observed 30 min after α-MSH (100 μg kg^{-1}) by atropine 10 mg per kg injected 15 min before the peptide (□). Saline only (●). *d*, Mean fluorescence intensities in rats bearing lesions of area postrema as observed 30 min after i.p. injection of 100 μg per kg α-MSH (□) or saline (▲). Saline in non-lesioned animals (●). Numbers refer to the rats shown in Fig. 2. The values represent the combined right and left sides of the arcuate and nigral DA neurone groups; no differences were found between the two sides after lesions of area postrema. For each rat, the two brain pieces containing hypothalamus and midbrain were worked up together for microfluorimetry but investigated by different observers. The arcuate nucleus was studied at 15 antero-posterior levels (7-μm sections, distance between levels, 84 μm) starting at the anterior border of the external layer of the median eminence, the substantia nigra at 8 levels (distance between levels, 42 μm) starting at the anterior end of the fossa interpeduncularis[4,6]. In the former all visibly fluorescent catecholamine-containing cells were measured on both sides at each of these levels (mean 215±47 per rat), whereas in the latter 20 neighbouring cells per section were measured on one side starting at the dorsolateral corner of zona compacta (162±13 per rat, except for lesioned rats where both sides were studied: 279±41 per rat). The relative fluorescence intensity of a cell is defined by $i_r = (c-t)/(g_{NA}-g_t)$, c = absolute intensity of the cell, t = mean background fluorescence of neighbouring tissue, g_{NA} and g_t = mean intensities of noradrenaline-containing and noradrenaline-free standards of that section. For statistical analysis, the values were transformed into natural logarithms. Means of the transformed values are shown. Data were analysed by variance analysis followed by comparison of experimental groups with Scheffe's method of linear contrasts[4,5].

reported after manipulations of the pituitary adrenal axis[12]. Our results do not exclude an action of $ACTH_{1-24}$ on the two DA systems, but they indicate that this peptide was less effective than α-MSH in our experimental conditions.

The interpretation of central effects of peptides is complicated by the existence of the blood–brain barrier. Recent studies with labelled α-MSH suggest that the hormone may reach various brain regions, but its cellular localisation in brain tissue remains obscure[13]. The influence of α-MSH on extinction of a conditioned avoidance response is abolished by bilateral lesions in the parafascicular nuclei of the thalamus[14]. Although our observations need not be related to this particular aspect of MSH action, it may be noted that both DA neurone groups reacted to electrical stimulation in this nucleus and in neighbouring areas[6]. These observations, together with results of lesions in the dorsomedial tegmentum of the lower brainstem[6], seemed suggestive of a possible role of ascending projections. We focused our attention on the area postrema which is situated outside the blood-brain barrier[15]. Selective destruction of this area (Fig. 2) prevented the reaction of the arcuate DA neurones to α-MSH in four out of six rats (Fig. 1*d*, $P < 0.01$). In two rats with a partial response, we found intact tissue at the

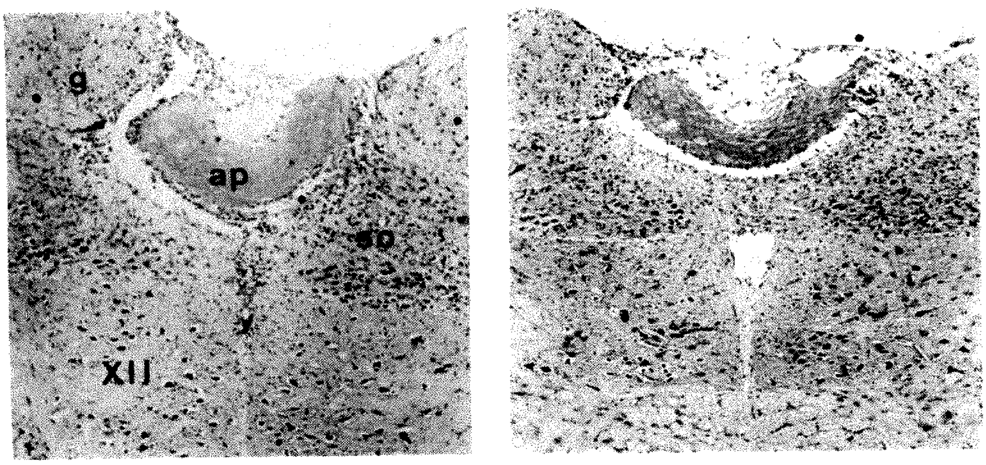

Fig. 2 Lesion of area postrema in rats nos 531 (left) and 533 (right). The lesion completely destroyed area postrema (ap) but impinged only slightly upon the dorsomedial corner of the nucleus of the solitary tract (so) and the medial edge of the nucleus gracilis (g). XII = nucleus nervi hypoglossi. Electrolytic lesions (250 μA, 60 s) were performed in gammabutyrolactone anaesthesia (750 mg kg^{-1} i.p., 1 h) according to coordinates calculated from various lesions in the lower brainstem, 2 weeks after ovariectomy. α-MSH was injected 5 d later between 15.00 and 16.00, after the usual 1-d steriod pretreatment. The rats recovered well from the operation and showed no neurological disturbances. They lost 6% of body weight, as did animals with ineffective electrode placements (×49.2).

posterior and anterior extremities of area postrema, respectively. In all rats, the reaction of the nigral DA neurones was not only blocked but apparently reversed, as mean intensity decreased to below the level of saline-injected intact rats ($P < 0.01$; saline-injected lesioned rats exhibited intermediary levels). Rats with electrode placements in the fourth ventricle in front of area postrema resulting only in a slight superficial damage to the ventricular wall, exhibited the usual reaction to α-MSH (mean intensity ±S.D. of these 3 rats (arcuate–nigral DA group): 3.965±0.3966 ($n = 202$)/4.386±0.3191 ($n = 240$); 3.837±0.4470 (140)/4.282±0.3570 (241); 3.987±0.6252 (103)/ 4.354±0.3561 (240).)

The effect of α-MSH thus seems to depend on the integrity of area postrema. It seems conceivable that α-MSH acted on this area, but a modulatory action of the peptide exerted at another brain level on an influence arising from area postrema, cannot be ruled out. The observations on the nigral DA neurones indicate that the effect of the lesion may be a complex one. The projection systems involved remain to be characterised. As atropine blocks responses of both DA neurone groups to electrical stimulation in various extrahypothalamic areas[5,6], we investigated its effect (Fig. 1*c*). Atropine completely prevented the intensity change in the nigral DA neurones ($P < 0.01$ against MSH without atropine). In the arcuate nucleus, the response was only partially reduced. Thus, cholinergic systems seem to be involved in the peptide effect, but the circuitry may differ in detail with respect to the two DA neurone groups.

We thank Miss R. Böswald and Mrs Z. Hefti for technical assistance. The study was supported by the Swiss NSF, the Hartmann-Müller Stiftung and the Jubiläumsspende of the University of Zürich.

Possible relationship between glial cells, dopamine and the effects of antipsychotic drugs

THE hypothesis that a functional excess of dopamine underlies many of the abnormalities seen in schizophrenia is receiving much attention. The supporting evidence is principally pharmacological. There is a correlation between antipsychotic drug action and the ability of a neuroleptic drug to block dopaminergic transmission[1–3]. The exact site of antipsychotic drug activity is not known and evidence for the presynaptic inhibition of dopamine release[4], as well as the blockade of postsynaptic receptors[5,6] has been presented to explain neuroleptic drug action. Studies of binding properties of the dopamine receptor, however, provide a coherent explanation of neuroleptic drug action. Butyrophenones, phenothiazines, thioxanines and diphenylbutylpiperadines inhibit ^{3}H-haloperidol binding to a central nervous system (CNS) membrane fraction in exactly the order of their clinical potency[7–10]: the inhibition occurs at drug concentrations similar to those expected in the CNS of patients taking these drugs. These results with ^{3}H-haloperidol, a dopamine antagonist, are used to argue that neuroleptics bind to postsynaptic dopamine receptors, and are effective by decreasing the activity of pathways using dopamine as their neurotransmitter. On the other hand, dopamine-sensitive adenylate cyclase is associated with the postsynaptic receptors[5,11], yet the inhibition of this enzyme by neuroleptic butyrophenones does not correlate with *in vivo* or clinical potency. The difference between butyrophenone inhibition of ^{3}H-haloperidol binding and inhibition of adenylate cyclase has been attributed to "variable degrees of coupling of dopamine receptor sites with the adenylate cyclase"[9]. Alternatively, there could be several dopamine sensitive adenylate cyclases with differing binding affinities and localisations: this is suggested by the presence of this enzyme in several tissue culture lines of glia[12]. Lesion studies show that the enzyme is not localised presynaptically in the caudate nucleus[13] or in the substantia nigra[14]. The only defined dopaminergic receptors in the substantia nigra are localised on dopaminergic neurones[15], and the elimination of these cells as the site of the enzyme was established by unilateral injections of 6-hydroxydopamine which removed these cells[14]. It therefore seems necessary to define more exactly the site of the dopamine binding receptor and the dopamine-stimulated adenylate cyclase. We report here that a large proportion of CNS dopamine haloperidol binding sites seem to be present on glial membranes and may be associated with an adenylate cyclase localised on these membranes.

We undertook to localise dopamine and haloperidol binding by fractionating rabbit cortex and bovine caudate and cortex. Synaptic fractions were prepared by the method of Gray and Whittaker[16], and the P_2 pellet of this preparation was used as a cell-free CNS membrane fraction. Glial cell fractions were prepared[17] and a C-6 cultured glial cell line was used for testing a clonal glial cell line. Binding assays were carried out in the presence of D and L butaclamol. Only the D isomer is active pharmacologically in blocking dopamine binding or as a clinical neuroleptic. Thus the difference between labelled dopamine and haloperidol binding in presence of the two isomers is taken as a measure of the blockade of specific dopamine receptors[7–10]. The assay used was essentially the centrifugation assay of Seeman *et al.*[8]. Although the filtration assay used by these workers and Snyder's group[7,9] seemed to give similar results, we did not achieve the precision using this assay that was achieved using centrifugation and ^{14}C-inulin to account for trapped external media in the pellet. Assay conditions were as in ref. 8 except that a different monoamine oxidase inhibitor (10.5 μM pargyline-HCl) was added to buffer solutions.

Our initial results with fractions isolated from rabbit cortex showed some purification of dopamine binding in the membrane fraction (P_2 pellet) derived from CNS homogenate, but little subsequent purification when a synaptosomal fraction was isolated. This prompted us to look at the binding of ^{3}H-dopamine and ^{3}H-haloperidol on fractions isolated from beef caudate. The results in Table 1 clearly show that although there is some purification of the receptor in isolating the P_2 pellet, little further enrichment occurs when this fraction is subjected to density gradient centrifugation to isolate synaptosomes. After obtaining these results fractions enriched in astroglia were obtained from bovine caudate. An excellent glial cell fraction was isolated using the method for rabbit cortex with a slight modification

Table 1 Binding of ^{3}H-dopamine and ^{3}H-haloperidol, and activity of glutamic acid decarboxylase (GAD) in fractions isolated from the caudate nucleus of bovine brains

	Dopamine binding Δfmol per mg protein	Haloperidol binding Δfmol per mg protein	GAD activity μmol per mg per h
Homogenate	9.25 ± 3.4	3.9 ± 1.1	28.6
P_2 fraction	17.65 ± 3.7	3.8 ± 0.9	54.8
Synaptosomal fraction	21.00 ± 3.5	6.5 ± 1.3	59.8
Glial fraction	35.05 ± 0.7	16.1 ± 0.9	4.0

Dopamine binding was measured with a final concentration of 1 nM ^{3}H-dopamine in the presence of 1 μM (+) or (−) butaclamol. Haloperidol binding was measured with 1 nM ^{3}H-haloperidol in the presence of 0.1 μM (+) or (−) butaclamol. The difference in binding between (+) butaclamol, a potent neuroleptic drug, and (−) butaclamol, an inactive drug, is taken as the stereospecific binding of the ligand. Binding assays represent triplicate determinations on at least two different glial cell preparations.

in the final Ficoll gradient[17]. The glia were collected between Ficoll solutions having refractive indices of 1.3633 and 1.3714, respectively. Binding studies in homogenates of these glial cells revealed a considerable purification of the receptor. This unexpected result suggests that the receptor which mediates neuroleptic drug activity is localised on glial membranes.

To assure that both dopamine and haloperidol binding take place on glial membranes we carried out several checks on the purity of our fractions. Morphological investigation by light and electron microscopy suggested that approximately 60% of the synaptosomal pellet is synaptic material, consistent with our previous findings on synaptic fraction purity[18]. The glial fractions also contain appreciable cell debris and, when viewed in the light microscope, 20% of the material seemed to be of non-glial origin. To quantitate this we assayed glutamic acid decarboxylase (GAD), the γ-aminobutyric acid (GABA) synthesising enzyme, in our fractions. The caudate is rich in GABA[19] and GAD has been found almost exclusively in synaptic regions[20]. The enzyme was assayed by the method of Roberts and Simonsen[21]. The results suggest that there is enrichment of synaptic material containing GAD in both P_2 and synaptosomal fractions while there is almost no GAD present in the glial fractions (Table 1). In addition, dopamine or haloperidol binding activity was found in a homogenate of C-6 glial cells, cells originating from a cloned line of rat glioma cells[22]. Furthermore, the glial dopamine-binding receptor seemed to be localised to regions of brain rich in dopamine in preliminary experiments.

To examine the possibility that glial dopamine sensitive adenylate cyclase could be associated with the binding site measured in either the ^{3}H-dopamine or ^{3}H-haloperidol assay, we examined the purification of the enzyme during cellular and subcellular fractionation. Cyclic 3′-5′ AMP was measured in fractions using a modification of the protein binding assay of Gilman[23] (from Amersham Searle). The difference between dopamine-stimulated activity and basal activity was taken as a measure of the dopamine sensitive enzyme. The results of measurements on fractions from bovine caudate show that the enzyme activity is purified to approximately the same extent in glial cells as the binding site for ^{3}H-dopamine or ^{3}H-haloperidol. The enzyme showed 3.8-fold higher activity in the glial fraction than in the crude homogenate, and the binding of dopamine and haloperidol are similarly increased by fourfold. This finding, coupled with the results of Schubert *et al.*[12] demonstrating that clonal lines of glia contain a dopamine-stimulated adenylate cyclase and that in one glial line this enzyme was inhibited by haloperidol, suggests that the receptor in caudate could be an adenylate cyclase localised in glial cells.

The finding of a dopamine binding site on glial cells which may be associated with an adenylate cyclase suggests that a mechanism exists which would cause an increase in cyclic AMP in glia in response to neronal activity. Such a metabolic response to neural release of neurotransmitter provides the initial step in what could be an important feedback control regulating neuronal activity. The morphology of the synapse is consistent with such a control system, for synapses are surrounded by an astroglial sheath[24]. Such a control system could involve changes mediated by cyclic AMP analogous to the increased glycogen breakdown seen in skeletal muscle[25] or membrane permeability changes as seen in smooth muscle[26], both mediated by a catecholamine-sensitive β-adrenergic receptor. Such an intercellular control provides a mechanism through which neuroleptic drugs could have a regionalised effect on CNS activity and dampen a wide variety of functions. This is an interesting possibility in view of the variety of symptoms seen in psychotic illness and the fact that neuroleptic drugs are neither specific nor curative in schizophrenia. The results of this preliminary study thus suggest that the receptor which correlates with the site of neuroleptic drug binding may reside on glial membranes and thus point to a possible mediation of neuronal activity by glial cells.

Human prolactin-responses to neuroleptic drugs correlate with antischizophrenic potency

THE secretion of prolactin, a pituitary hormone, is regulated by inhibitory and stimulatory influences from the hypothalamus. The primary influence is tonic inhibitory[1]. Dopamine, a neurotransmitter, has a major direct and/or indirect role in mediating this inhibition upon the prolactin cells in the pituitary gland. This is documented by studies *in vitro*[1], *in vivo*[2] and in man[3]. All known neuroleptic, antischizophrenic drugs share one characteristic—they block dopaminergic transmission[4–7]. This action is hypothesised to be associated with their antischizophrenic effects (dopamine hypothesis)[8,9]. Dopaminergic blockade is, very likely, also the primary mechanism of neuroleptics when inducing prolactin release via disinhibition[1,10]. There is no evidence that neuroleptics release prolactin via stimulatory influences. We believe the prolactin response to neuroleptic drugs to be a valid and reliable model of dopaminergic blockade in man (Langer *et al.*, unpublished). Intesting the dopamine hypothesis of antischizophrenic drug action in man we postulated that comparing drug effects after acute intramuscular administration, a high correlation between prolactin releasing and antischizophrenic potencies of neuroleptics would be found.

Twelve healthy young male volunteers (medical students) were screened medically and psychiatrically for participation in the study and informed consent was obtained. On an average, each subject participated in seven weekly sessions, each starting at about 9 a.m., after an overnight fast, and lasting for 3½ h. At each session a single drug and dose was intramuscularly (i.m.) administered 30 min after a small angiocath had been inserted into a forearm vein of the recumbent subject. Throughout the study, blood samples were withdrawn at 15-min intervals into heparinised tubes. The plasma was immediately separated after the study and frozen at –20 °C. Prolactin was analysed in duplicate by radioimmunossay[11]. All samples from each subject were determined in one assay; variation between duplicate samples was 5.3%.

The following antischizophrenic drugs were selected because of their wide use in clinical psychiatry (which results in adequate documentation of their antischizophrenic effects) and because they are all intramuscularly administerable: haloperidol (0.25, 0.5, 1.0 and 1.5 mg), chlorpromazine (25.0 mg), prochlorperazine (2.5 and 5.0 mg), trifluoperazine (4.0 mg), perphenazine (1.0 mg), fluphenazine (0.35 mg), and thiothixene (0.25 and 0.5 mg). There is considerable interindividual variation of the prolactin response to a neuroleptic drug. We minimised the variation by (1) testing several drugs within the same subject, and (2) relating each subject's peak prolactin response to a neuroleptic to his own haloperidol dose–prolactin response curve. Haloperidol, a relatively specific dopamine receptor blocker and potent antischizophrenic drug, was chosen as reference drug for prolactin releasing and clinical potencies. So, all subjects were first tested with usually four different doses of haloperidol. Five of the subjects were then tested with two different doses of prochlorperazine and two different doses of thiothixene. We demonstrated that the dose–prolactin response curves to haloperidol, prochlorperazine and thiothixene, representing three different chemical classes of neuroleptics, were parallel (Langer *et al.*, in preparation). Eight of the subjects then received single doses of the various neuroleptics in doses which, according to a pilot study, induced about 50% of maximal prolactin release. To evaluate relative potencies, the peak prolactin response to a drug was related to the individual haloperidol dose–prolactin response curve. The potency per mg of each drug in releasing prolactin was then calculated in per cent potency of haloperidol in releasing prolactin. Finally, we related this value to the clinical potency of each drug relative to haloperidol. Data on antischizophrenic potencies of drugs after acute parental administration were derived from standard clinical references[12,13].

Our results (Fig. 1) show that seven widely used antischizophrenic drugs show a very high correlation ($r = 0.956$) between their potency to release prolactin in man and their potency in the acute treatment of schizophrenic patients.

We thus hypothesise that mechanisms mediating these two different drug effects have at least one critical variable in common—the blockade of dopaminergic transmission. The parallelism of dose–prolactin response curves of the three representative drugs also indicates a common, dopaminergic, mechanism. We limit the interpretation of our findings to the seven antischizophrenic drugs we tested, which constitute the majority of drugs used in the treatment of schizophrenia. So far, only one antischizophrenic, antidopaminergic drug (clozapine) shows inadequate prolactin-releasing activity. This might indicate that (1) increase of prolactin is not necessary for therapeutic response, and (2) different dopaminergic systems are primarily involved in prolactin-releasing and antischizophrenic effects. Prolactin release by neuroleptics probably reflects blockade of dopaminergic transmission at the hypothalamic and pituitary level, rather than at extrahypothalamic (possibly limbic) loci which are hypothesised to be associated with the therapeutic actions of antischizophrenic drugs[14]. It is noteworthy that schizophrenic patients generally require treatment of higher doses of a neuroleptic than are needed to achieve maximal prolactin release (1–2 mg haloperidol i.m. per 70 kg or dose equivalence of another neuroleptic drug).

This study supports in man the hypothesis that blockade of dopaminergic transmission is a characteristic of the neuroleptic drugs we tested and associated with their antischizophrenic effects. The questions whether the pathogenesis of schizophrenia specifically involves a disturbance in brain dopaminergic function and whether drugs necessarily have to interfere with

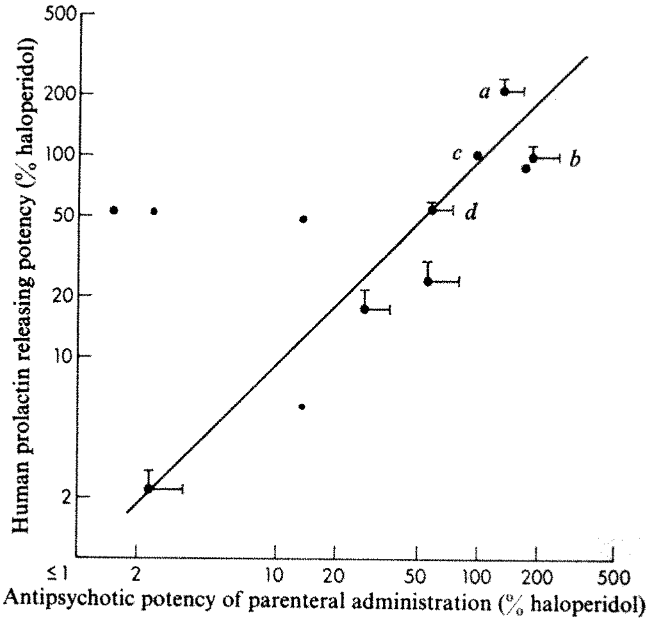

Fig. 1 The potency of seven antischizophrenic drugs in inducing prolactin release in man correlates with their potency in treating schizophrenic patients. Drugs tested (number of subjects in parentheses): *a*, thiothixene (6); *b*, fluphenazine (5); *c*, haloperidol (12); *d*, perphenazine (6); *e*, trifluoperazine (7); *f*, prochlorperazine (7) *g*, chlorpromazine (8). All values refer to an acute intramuscular administration and are expressed in per cent potency of haloperidol. Each value is the mean; vertical bars show the s.e.m. of prolactin values, horizontal bars the range of potency with conventional treatment. $y = 0.212 + 0.93x$, $r = 0.956$.

dopaminergic transmission to achieve antischizophrenic effects await the elucidation of the biological basis of schizophrenia.

Defective dopaminergic regulation of prolactin secretion in a rat pituitary tumour cell line

IT is firmly established that certain rat[1,2] and human[3,4] pituitary tumours hypersecrete prolactin (PRL). Pituitary PRL secretion is probably under the dual control of hypothalamic prolactin-inhibiting and -releasing factors, and defective secretion in one or both of these factors could produce abnormal PRL secretion[3]. An alternative explanation for the *in vivo* PRL secretory defect of certain pituitary tumours is defective reception by the tumour of an appropriate hypothalamic endocrine signal. To test this latter hypothesis, we evaluated the effects of various catecholamines on PRL secretion in a cloned rat pituitary tumour cell line (GH_3). Catecholamines are potent inhibitors of PRL secretion[5], and it is postulated that the prolactin inhibiting factor may be a catecholamine[6,7]. We report here that dopamine failed to inhibit PRL secretion from the pituitary tumour cultures, whereas, other catechols added to our normal and pituitary tumour monolayer cultures suppressed prolactin release into the medium. In addition, apomorphine, which is postulated to be a specific dopaminergic agonist[8–10], appropriately suppressed PRL secretion in the tumour monolayer cultures. Our results therefore provide evidence for an unusual dopaminergic defect in the GH_3 rat pituitary tumour cell line.

The pituitary tumour cell line was acquired from ATCC and was subcultured according to the method of Sato and Tasjian[11]. Our normal rat pituitary monolayer cultures were produced by a modification of the method of Vale *et al.*[12] (Fig. 1). Rat PRL was measured by radioimmunoassay[13].

Figure 1 illustrates that dopamine not only failed to suppress PRL secretion, but paradoxically stimulated PRL release in the pituitary tumour cell cultures. Significant PRL stimulation, however, was observed in most but not all of the individual experiments. Conversely, dopamine produced a significant suppression of PRL secretion in the preconfluent normal rat monolayers. Other catecholamines added to the GH_3 cells and the normal rat pituitary cultures also produced suppression of PRL secretion.

The incubation conditions of our monolayer cultures for both the tumour and normal pituitary cells were similar (see Fig. 1), except that 15% horse and 2.5% foetal bovine serum were used with the tumour cells, and 20% foetal bovine serum was used in the normal rat monolayers. Dopamine is known to be susceptible to oxidant stress[14] and we therefore had to demonstrate that the failure of dopamine to inhibit PRL secretion in the tumour cultures was not secondary to its rapid destruction by the horse serum. When dopamine was added to the normal pituitary cultures with 15% horse serum and 2.5% foetal bovine serum, PRL secretion was significantly inhibited, whereas dopamine added to the tumour cultures with 20% foetal bovine serum still failed to inhibit PRL secretion. Hence, failure of dopamine to inhibit prolactin secretion in the pituitary tumour monolayer cultures was not secondary to rapid destruction by the horse serum.

Another possible explanation for the lack of dopamine inhibition of PRL secretion was that it was a dose-related event. It has been suggested that adrenaline at low doses *in vitro* produced stimulation, and at high doses inhibition of PRL secretion[15]. To demonstrate that a biphasic effect was not present in the tumour cultures, PRL secretion was evaluated after addition of various concentrations of dopamine over a 40-fold range. In this experiment, each concentration of dopamine failed to significantly alter PRL secretion in the pituitary tumour cultures, whereas there was progressive inhibition of PRL secretion in the normal cultures of 25% by 1.5×10^{-6} M, 65% by 1.5×10^{-5} M, and 80% by 6×10^{-5} M dopamine. Hence, the PRL secretory defect was not explainable on the basis of the concentration of dopamine used in the experiments and was consistent with the presence of a dopaminergic defect in this pituitary tumour cell line. The observation, however, that apomorphine significantly suppressed PRL secretion in the tumour cultures (Fig. 1, Table 1) was difficult to reconcile with this conclusion. Apomorphine has been shown to be a dopaminergic agonist[8–10] and the ability of pimozide, a specific dopaminergic blocking agent[16–18] to inhibit the suppressive effect of apomorphine on PRL secretion in the tumour cultures (Table 1) suggested that certain aspects of dopaminergic function were intact in the tumour cultures. Recent evidence has suggested that apomorphine may act only at presynaptic dopaminergic sites[19], however, this finding does not explain our observations, as dopamine probably acts at both pre- and postsynaptic receptors[19]. It is possible therefore that the tumour cell line may have acquired a dopaminergic defect that permitted suppression of PRL secretion with apomorphine and yet failed to respond in a similar manner to dopamine. Alternatively, our data suggest that dopamine and apomorphine act at different sites in the rat pituitary. Hence defective dopaminergic regulation of prolactin secretion exists in this rat pituitary tumour cell line and may be related to the excessive prolactin secretion exhibited by certain rodent and human pituitary tumours.

Table 1 The effect of a dopamine agonist and antagonist on pituitary tumour prolactin secretion.

Treatment	n	Rat PRL (μg per well) 0 h	Rat PRL (μg per well) 6 h
Controls	4	1.40±0.09	1.89±0.12
APO	5	1.16±0.19	1.37±0.11*

APO+PIM	5	1.53±0.06	1.92±0.04

Data are means±s.e.m. APO, apomorphine 2.5×10^{-5} M; PIM, pimozide 4.0×10^{-6} M.
*$P<0.02$.

This latter postulate, however, has to be viewed in the light of a large number of reports that indicate that L-dopa and/or its metabolite, dopamine, can inhibit rodent[2] and human[3,4,20]

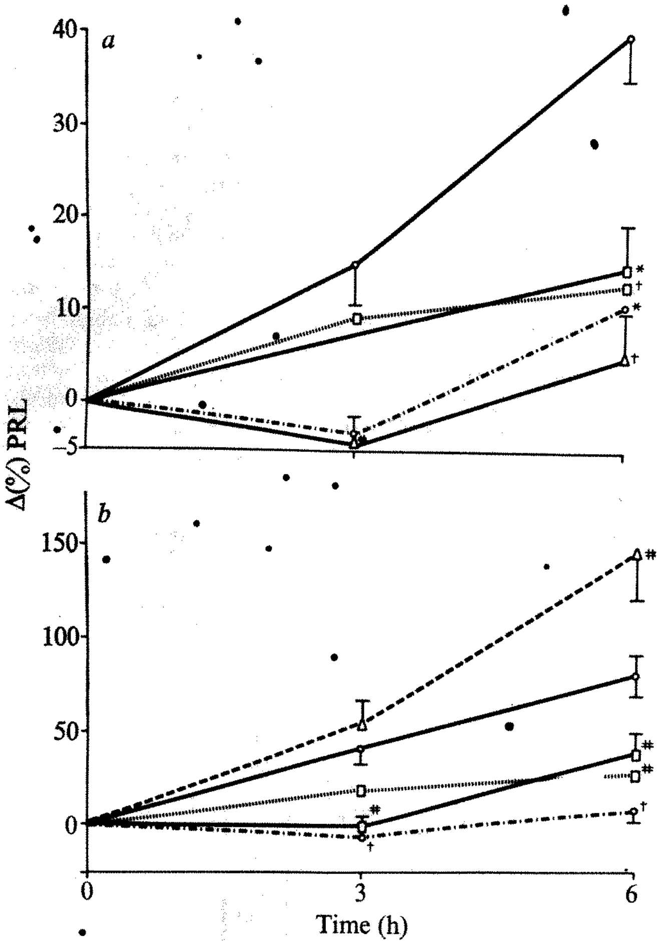

Fig. 1 The effect of catecholamines on PRL secretion in *a*, normal and *b*, tumour-bearing rat pituitary monolayer cultures. Normal cultures were prepared from anterior pituitaries removed from Holtzman male rats (200–300 g) immediately after killing by guillotine. Tissues were minced into 2-mm pieces with a sterile scalpel, and incubated for 45 min with gentle stirring at 37 °C with 0.5% collagenase (CIS Worthington) in 1X Detroit MEM with HEPES buffer at *p*H 7.2, supplemented with gentamycin (50 μg ml^{-1}), 1X amino acids (1 ml per 100 ml), 1 mM sodium pyruvate (1 ml per 100 ml), and 20% foetal calf serum (Grand Island Biochem.). The cell suspension was then centrifuged at 650*g* for 7 min. The supernatant was removed and the pellet resuspended with 10 ml of medium. This centrifugation and pellet resuspension in fresh medium was repeated once, and the final suspension was placed in 60×15 mm Linbro plates at a concentration of 3×10^4 to 7×10^4 cells per well to a final volume of 4 ml per well. All incubations were carried out at 37 °C (95% room air, 5% CO_2). The growth medium on these pre-confluent cultures was changed every 2–3 d and 10–24 h before the beginning of each experiment. At the beginning of an experiment, a 200-μl aliquot of the medium was removed from each well and stored at −20 °C for radioimmunoassay. The test substances were then added to each well and the progress of the experiments was followed by taking additional samples of the medium at 3 and 6 h. Rat PRL was measured by radioimmunoassay using RP-1 obtained from the NIAMDD as standard with tubes added to the assay to control for serum effects produced by the tissue culture medium. All of the catecholamines were prepared in the dark on ice immediately before addition to the culture to minimise oxidation. GH_3 cells (passage 20) were subcultured with trypsin (0.01 M) according to the methods of Sato and Tashjian[5], and seeded in 60×15-mm Linbro plates at a concentration of 2×10^5 to 4×10^5 cells per well to a final volume of 4 ml per well. The culture medium consisted of Hams F-10 medium, supplemented with 2.5% foetal bovine serum, and 15% gamma-globulin-free horse serum (Grand Island Biochem.) and the *p*H was adjusted to *p*H 7.2. These pre-confluent cultures were allowed to grow for at least 72 h before study. After an experiment PRL secretion in each monolayer culture returned to its basal secretory rate. The normal and tumour figures represent pooled data from 8 and 9 separate experiments, respectively. PRL concentrations are expressed as % change from the basal PRL level. The data was transformed because of variations in basal PRL concentration of the individual wells between experiments and occasionally within the same experiment. Vertical bars represent s.e.m. and Student's *t* test was used to evaluate the means with a P of < 0.05 being considered significant. △ Represents results for dopamine 4×10^{-5} M ($n = 25$ in *a*; 34 in *b*); ○ (on solid line) controls ($n = 41$ in *a*, 50 in *b*); ○ (broken line), adrenaline 4.5×10^{-5} M ($n = 5$ in *a*, 9 in *b*); □ (solid line), apomorphine 2.5×10^{-5} M ($n = 9$ in *a*, 13 in *b*); □ (broken line), noradrenaline 4.5×10^{-5} M ($n = 13$ in *a*, 11 in *b*); significance levels shown as *, $P < 0.05$; ‡, $P < 0.002$; †, $P < 0.002$.

pituitary tumour PRL secretion. Interpretation of this *in vivo* data is complicated, however, by the observation that α adrenergic blockade can inhibit the effect of L-dopa in decreasing rat pituitary tumour PRL secretion[2]. In addition, a recent report by Van Der Gugten *et al.*[21] suggests that L-dopa decreased serum PRL concentrations in the rat in part by stimulating the peripheral uptake of PRL. Thus the reported suppressive effects of L-dopa on pituitary tumour PRL secretion may not be exerted via the dopaminergic receptor. Whether the dopaminergic defect described here is unique to this cloned cell line, or reflects a generalised defect in PRL secreting pituitary neoplasms remains to be established.

Prolactin–progesterone antagonism in self regulation of prolactin receptors in the mammary gland

THE role of prolactin during growth of the mammary gland and in lactation is well established (see ref. 1 for review) and the antagonising action of progesterone on lactogenesis (but not on mammary growth) has been recognised[2–4]. A specific receptor for prolactin has been described[5] and purified[6] and it seems that the level of this receptor in the target cells is very sensitive to hormonal environments and might be one of the essential parameters which modulates the intensity of prolactin action. Titration of this receptor under controlled hormonal conditions has been mainly performed in the liver and its concentrations found to be sensitive to oestrogens[7]; this effect may be amplified or even mediated by prolactin itself[8]. We have shown[9] that the number of prolactin receptors in the mammary gland of pregnant or lactating rabbits undergoes a sudden increase at the onset of lactation but that the K_a of the receptor–hormone interaction remains constant. The question arises as to which hormonal environment is required for this amplification; is the inhibitory action of high progesterone levels on lactogenesis associated with a reduction of receptor concentrations? We describe here a study of this possibility and of the positive regulation of prolactin on its own receptors in the rabbit mammary gland. We extend to the mammary gland the stimulating effect of prolactin on the levels of its receptors and demonstrate an antagonising action of progesterone on this process.

New Zealand rabbits (4–6 months old) were used either in pseudopregnancy (mating with a vasectomised male) or at late pregnancy. Pseudopregnant animals were treated intramuscularly (i.m.) with 400 or 50 IU ovine prolactin (Byla) divided into four injections (two per d) over 48 h. Progesterone (Roussel) when administered was injected i.m. at a daily dose of 10 mg (two times 5 mg), starting the day before prolactin treatment. *In vivo* desaturation of receptor sites of their endogenous prolactin with bromocriptine (CB 154, Sandoz) was performed by injecting the drug subcutaneously (2 mg) 36, 24 and 12 h before the animals were killed, the first injection taking place 12 h after the last prolactin (and progesterone) treatment. Receptors were assayed as described before[9] by estimating their total amount and their affinity constant according to the Scatchard plots[10] obtained with varying concentrations of ovine prolactin labelled with ^{125}I and substracting the non-specific binding. Protein concentrations were assayed according to Lowry *et al.*[11] and DNA according to Morimoto *et al.*[12].

Figure 1 shows that the total number of receptors per mg DNA in the mammary gland increases strikingly at parturition as shown previously[9], but that this increase is inhibited by 60% ($P < 0.01$) when the prolactin surge at parturition is blocked by injecting CB 154 to the animals on the last day of pregnancy. In both cases, prolactin receptors were measured 6 d after parturition, since this delay corresponds to the highest levels normally observed. Interestingly the reduction in prolactin receptors was associated with a significant reduction in milk production (results not shown). This experiment is an illustration of the prominent role of prolactin inducing its own receptor at parturition, although it must be emphasised that this role probably requires a definite hormonal environment, since prolactin levels remain high in the rabbit at the onset of lactation, but seem unable at this period to act strongly on receptor concentrations. Figure 2 shows the effect of four doses of 12.5 IU and four of 100 IU of prolactin on the pseudopregnant rabbit and demonstrates the ability of the higher dose of this hormone to increase its receptors in the mammary gland. The lower dose, though inactive when injected during 48 h, becomes effective when administered through more extended periods (results not shown). Progesterone injected simultaneously with a total dose of 400 IU of prolactin completely prevents any increase of the prolactin receptors in the mammary gland. This result extends the classical inhibitory effect of

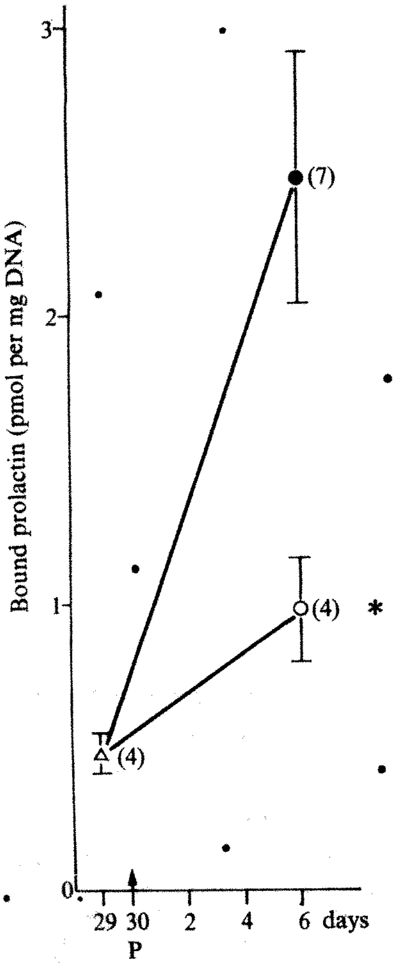

Fig. 1 Total number of prolactin receptors in the rabbit mammary gland titrated after 36 h *in vivo* desaturation. In the following conditions. △, Day 29 of pregnancy; ●, day 6 postpartum; ○, day 6 postpartum, prolactin surge at birth suppressed by ergocryptine (see text). Each point represents the mean±s.e. for the number of animals indicated in parentheses. The affinity constant of the hormone–receptor interaction did not vary ($K_a = 3 \times 10^9\ \mathrm{M}^{-1}$). *Significantly lower than control at the same day ($P < 0.01$).

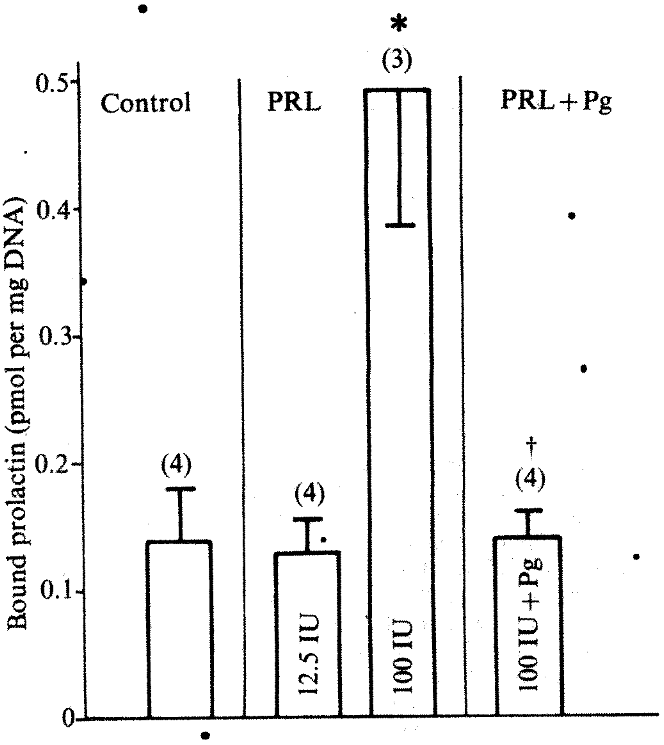

Fig. 2 Effect of prolactin (PRL) and prolactin+progesterone (PRL+Pg) injections on prolactin receptors concentrations in the mammary gland of 15 d pseudopregnant rabbits. Each point represents the means±s.e. for the number of animals indicated in parentheses. The affinity constant ($K_a = 3 \times 10^9\ \mathrm{M}^{-1}$) did not vary. *Significantly higher than control ($P < 0.025$). †Significantly lower than 100 IU prolactin treated animals ($P < 0.025$) and not different from control value.

progesterone on lactogenesis[2–4] to an additional parameter–receptor concentration; it is not known whether this parameter is causally related to the various amplification mechanisms which ultimately cooperate in lactogenesis, by modulating the information available to the target cell, or whether it is just part of the pleotypic action of prolactin on this cells protein synthesis.

It is thought that prolactin and progesterone receptors are both triggered initially by oestrogens[7,13], and hence might first appear in the mammary gland simultaneously with the oestradiol peak at the onset of pseudopregnancy. It is known that oestradiol induces its own receptors[14] and that prolactin at least amplifies its own receptor levels in the liver[8] and mammary gland (present results). In addition, progesterone counteracts both the self-regulated increase of oestradiol receptors[15] and the increase of prolactin receptors in the mammary gland (present result). The interrelations between the circulating concentrations of these hormones and the levels of their receptors thus seem complex and it may be relevant to emphasise that the prolactin effect on the pseudopregnant rabbit (Fig. 2) might be increased if this hormone were injected at a period when luteolysis should already have begun, resulting in lower progesterone levels. This view is supported by the obvious requirement for a specific hormonal environment (high prolactin levels, a cortisol peak and decreasing progesterone levels) for the efficient induction of prolactin receptors at parturition (Fig. 1).

The mechanisms by which prolactin and progesterone regulate prolactin receptors are a matter of conjecture and it is doubtful that these hormones act at precisely the same level on the complex sequence of events which result in the synthesis, intracellular transport and possible removal of the receptors. The so-called down regulation (that is, lowering of receptor levels by its specific hormone) has been shown to be due to accelerated removal or breakdown of the hormone–receptor complex (possibly by endocytosis) at least in the case of insulin[16,17]. This scheme should not apply to prolactin, which has just the opposite effect on its receptors. It remains to be shown to what extent this increase of receptors is due to an unmasking or recombination of previously inactive or segregated receptor molecules or to a *de novo* synthesis of these molecules.

Alteration in glucocorticoid binding site number during the cell cycle in HeLa cells

GLUCOCORTICOID stimulation of alkaline phosphatase (AP) activity in HeLa cells is believed to be mediated by steroid receptors[1,2]. When synchronised HeLa cells are exposed to glucocorticoids, an increase in AP activity is initiated during the synthesis phase of the cell cycle[3]. This 'S-phase dependency' suggests that the necessary components for cellular response to glucocorticoids are produced or altered during this time. Because the interaction of the steroid with its cytoplasmic receptor seems to be the first major intracellular event of the action of glucocorticoids, we have measured the glucocorticoid receptors present throughout the cell cycle in synchronised HeLa cells. We report here that although receptors are present throughout the cycle, the number per cell varies markedly within the cell cycle in both cytosols and whole cells.

HeLa S3 cells (adapted to suspension culture by Phillip Marcus, Albert Einstein Medical School) were maintained at a density between 2×10^5 and 6×10^5 cells per ml. The cells were synchronised by the double thymidine block procedure[4,5]. Samples of cells for receptor analysis were collected from the synchronised cultures at late G_1, S, mitosis and early G_1. Scatchard analysis of glucocortcoid-binding in HeLa cell cytosols was performed using dextran-coated charcoal to remove free steroid. Uptake by whole cells was studied using a modification of the techniques described by Munck and Wira[6].

As Fig. 1 shows, glucocorticoid receptors were present in cytoplasmic fractions at all stages of the cell cycle studied. Scatchard analyses of saturation curves indicate a single class of high affinity binding sites (Fig. 1). The affinities of the cytoplasmic receptors for dexamethasone did not vary by more than a factor of two and they agree with published results for dexamethasone-binding in other tissues[11]. The number of cytoplasmic dexamethasone-binding sites per cell doubled between late G_1 and S (Fig. 1). Cells collected at S showed maximal rates of incorporation of ^{3}H-thymidine. Between mid-S-phase and mitosis (4 h) there was a considerable reduction in cytoplasmic dexamethasone-binding per cell, which correlated with a doubling of cell number. By early G_1 there had been a small increase in binding. We have observed this pattern of alteration in numbers of glucocorticoid receptors in seven identical synchrony experiments. The data suggest that the number of cytoplasmic glucocorticoid receptors per cell doubles before mitosis, with less than half the complement available for assay in the daughter cells.

When the number of glucocorticoid-binding sites is expressed as a function of other biochemical parameters (DNA, protein and cell volume) (Table 1), a similar, cell cycle-dependent variation is seen, although it is less pronounced. This variation was also observed in all seven experiments.

We have assessed dexamethasone-binding after incubation of whole cells with the steroid at both 3 and 37 °C. Figure 2 shows the results of one of four nuclear translocation experiments performed on cells from separate synchronised populations.

As in studies of ^{3}H-dexamethasone binding in cytosols, the level of saturable ^{3}H-dexamethasone-binding in whole cells showed cell cycle dependence. Figure 2*a* shows that, as in other systems[11] most glucocorticoid-binding was restricted to the cytoplasmic fractions after incubation at 3 °C, with very little binding associated with the nucleus. Cytoplasmic binding in whole cells at 3 °C significantly increased between late G_1 and synthesis and decreased to $\simeq 1/2$ synthesis values after mitosis. Nuclear binding at 3 °C did not show similar cell cycle dependence. When cells were warmed to 37 °C (Fig, 2*b*) there was a significant increase in nuclear binding at each stage of the cell cycle, with a concomitant reduction in the level of cytoplasmic binding. Both cytoplasmic and nuclear binding at 37 °C showed the cell cycle dependence observed with cytosol at 3 °C (Fig. 1) and whole cell cytoplasmic fractions at 3 °C (Fig. 2*a*). Total-cell binding (cytoplasmic and nuclear) was similar when measured at 3 °C (Fig. 2*a*) or at 37 °C after 2 h at 3 °C (Fig.

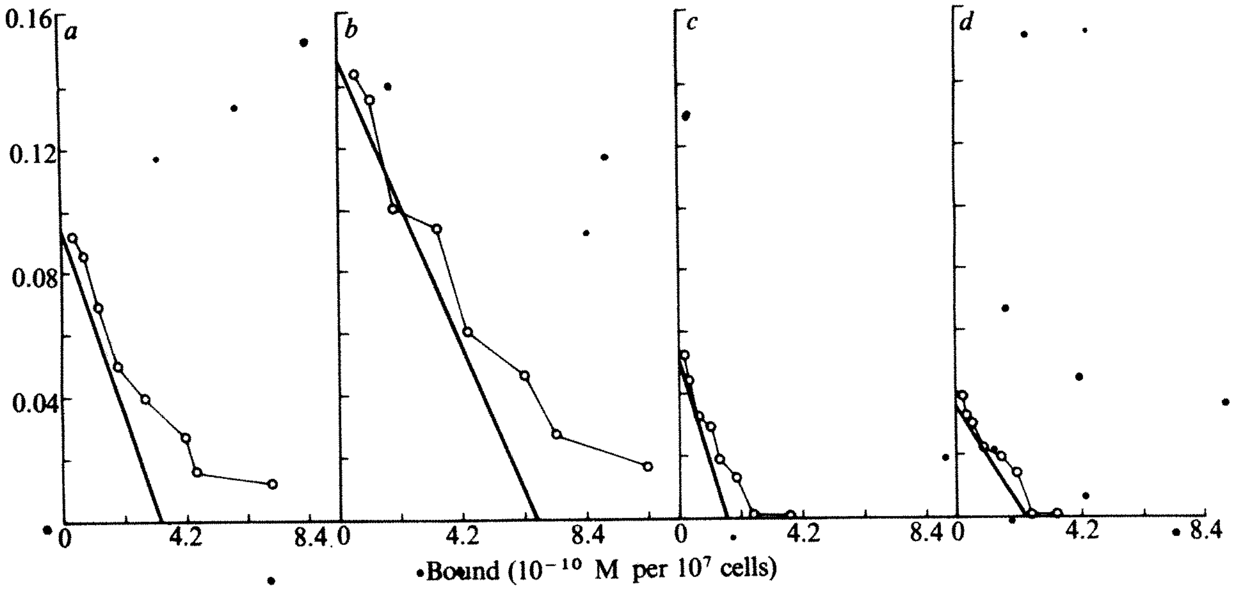

Fig. 1 Scatchard analysis of glucocorticoid—binding in HeLa cell cytosols. HeLa cells were grown in Joklik's modified Eagle's medium supplemented with 3.5% each of calf and foetal calf serum in the presence of kanamycin (10 μg ml^{-1}) in suspension culture at 37 °C. The cells have a doubling time of about 20 h. The cells were synchronised by double thymidine block[4,5]. They were grown in 2 mM thymidine for 16 h, followed by growth for 10 h in thymidine-free medium. Thymidine treatment was repeated for a further 14 h and the cells were washed free of thymidine. Growth was then resumed in thymidine-free medium; time of release from the second thymidine block is time 0. During late G_1 S, mitosis and early G_1, 200-ml samples of cells were collected and centrifuged at 600*g* for 5 min and the resulting pellet was resuspended in 1.5 ml of medium containing 10% glycerol. After a period of slow cooling, cells were kept frozen in liquid nitrogen. At the time of assay, cells were thawed at 23 °C and washed with 50 ml of serum-free medium. Freezing and thawing had no effect on receptor affinity and binding sites per cell when tested with randomly growing cells. The thawed HeLa cells were centrifuged and resuspended in 2.5 ml Joklik's medium (without serum) at room temperature and three 200-μl samples were removed for determination of cell numbers, DNA[7] and total cell protein[8]. The cells were then pelleted by centrifugation at 600*g*, the medium was aspirated off and 3.0 ml of ice-cold Tris-EDTA buffer (0.01 M Tris, 0.0015 M Na_2 EDTA *p*H 8.0) was added to each pellet. Cell pellets were homogenised at 0–3 °C with three 5-s bursts from a Polytron (Brinkman Instruments) at setting 5. All subsequent procedures were performed at 3 °C. The homogenates were centrifuged at 12,500*g* for 4 min in an Eppendorf model 5411 microfuge. The supernatants (cytosol) were decanted into glass tubes and divided into 50-μl samples of eight different concentrations of ^{3}H-dexamethasone (prepared in 0.9% NaCl) from 1×10^{-7} M to 1×10^{-10} M. The cytosols were incubated for 90 min at 3 °C' This time was sufficient to attain near-maximal dexamethasone-binding in cytosol from randomly growing HeLa cells, in mammary gland cytosol[9] and in muscle cytosol[10]. After this incubation, 100-μl samples of dextran-coated charcoal (1% Norit A and 0.1% dextran type 60 C in 1.5 mM $MgCl_2$) was added to each sample. The tubes were then vortexed and left standing to incubate for 15 min, and subsequently centrifuged at 12,500*g* for 2 min. Samples of 75 μl of the supernatant were placed into 5 ml of Bray's solution for determination of radioactivity. Duplicate 5-μl samples of the original ^{3}H-dexamethasone solutions used for incubation with cytosol were counted for determination of total steroid concentrations. The percentage of cells in mitosis was determined by monitoring a parallel culture of synchronised cells growing in the presence of colchicine (0.2 μg ml^{-1}). Cells from growing culture were counted microscopically in a haemocytometer. Radioactivity was determined in a Packard (3310) liquid scintillation spectrometer with a 25% efficiency for tritium. Each cytosol preparation was analysed for protein by the method of Lowry[9]. DNA was measured by a microfluorometric assay[10]. The cytocrit of each cell suspension was determined using a Drummond microhaematocrit, *a*, Late GI = 24,802 sites per cell; *b*, synthesis = 46,950 sites per cell; *c*, mitosis = 12,040 sites per cell; *d*, early GI = 16,615 sites per cell. The *K* dissociations ranged from 1.3×10^{-8} M to 2.6×10^{-8} M.

2*b*), indicating that equilibrium was probably attained within 2 h at 3 °C during each stage of the cell cycle.

Our results show that glucocorticoid-binding occurs in HeLa S3 cells throughout the cell cycle when measured in cytosols and in cytoplasmic and nuclear fractions of whole cells. The 'S-phase dependency' of stimulation of AP activity therefore cannot be attributed to an absence of glucocorticoid receptors or the failure of the steroid receptor complex to be translocated to the nucleus at other stages of the cell cycle. Although it is possible that a critical number of receptors is needed for AP stimulation, other factors are more probably involved, since some cells with fewer binding sites are responsive to glucocorticoid stimulation[11]. Of the factors that involve the receptor, the following are likely candidates: (1) modification of the receptor itself (not at the binding site); (2) lack of functional nuclear acceptor sites, or (3) an altered nuclear processing of the steroid receptor complex. These can all show cell cycle dependence.

We have demonstrated that in the conditions we used to synchronise HeLa cells, the number of cytoplasmic and nuclear dexamethasone-binding sites is regulated in a specific manner in relation to the cell cycle. The simplest interpretation of the observed doubling of the number of receptors at S is that this represents the synthesis of new receptor for passage to daughter cells. Histone synthesis at S is an example of a regulatory component that is synthesised at one phase of the cell cycle[12]. The increased number of receptors, however, may not result from the synthesis of new receptors but could reflect activation of a proreceptor, differential degradation of receptor molecules or

Table 1 Relation of cell cycle stage to cytoplasmic receptor concentration per unit of protein, DNA and cell volume

Cell cycle stage	Late G_1	S	Mitosis	Early G_1
Moles bound				
per 100 mg total protein	1.44×10^{-13}	2.0×10^{-13}	1.0×10^{-13}	1.70×10^{-13}
per 100 mg cytosol protein	1.45×10^{-13}	2.1×10^{-13}	1.5×10^{-13}	2.15×10^{-13}
per 100 μg DNA	1.42×10^{-13}	1.71×10^{-13}	0.68×10^{-13}	0.77×10^{-13}
per ml of packed cells	20×10^{-13}	24×10^{-13}	12×10^{-13}	22×10^{-13}

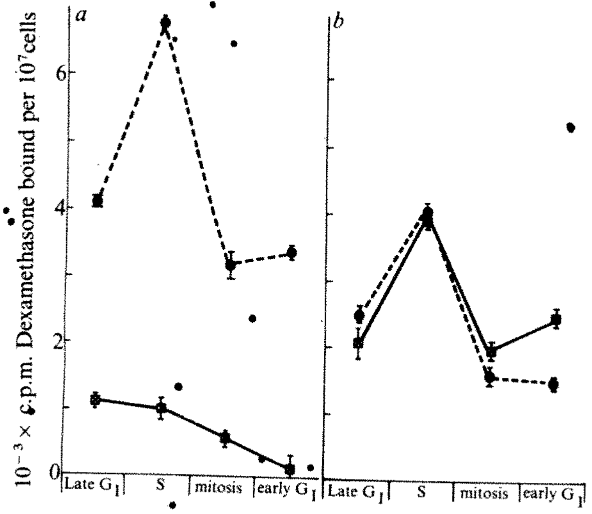

Fig. 2 Saturable cytoplasmic and nuclear ^3H-dexamethasone-binding in synchronised HeLa cells after incubation of whole cells with steroid. The thawed HeLa cells were suspended in 1.0 ml of ice-cold Joklik's medium without serum. Samples of 400 μl of cell suspensions from each stage of the cell cycle were incubated for 2 h at 3 °C (*a*) or 2 h at 3 °C plus 30 min at 37 °C (*b*) with $\simeq 1 \times 10^{-8}$ M ^3H-dexamethasone alone or ^3H-dexamethasone plus 1×10^{-6} M unlabelled dexamethasone. Saturable dexamethasone-binding was considered to be the difference between the observed binding with ^3H-dexamethasone alone and ^3H-dexamethasone plus unlabelled dexamethasone. Cytoplasmic (●) and nuclear (□) binding were measured in 20-μl samples of cells after cell lysis in dextran-coated charcoal (cytoplasmic) or 1.5 mM $MgCl_2$ (nuclear) as before[6]. A rapid freeze-thaw modification was used to ensure breakage of the cells. The values shown are the means ± s.e. of triplicate determinations of the saturable binding fraction from a single synchrony experiment.

masking or unmasking of the binding sites. If the doubling of receptor number between late G_1 and S represents synthesis of new receptors, these cells may provide an appropriate system for the isolation of receptor mRNA.

We thank Professor A Munck for suggestions and criticism and Sally Whitlock for technical assistance. This project was supported in part by grants from NCI, NIAMDD and NIH.

Biological activities of prostaglandin analogues and metabolites on bone in organ culture

PROSTAGLANDINS, especially the E-series, are potent stimulators of bone resorption in several *in vitro* systems[1–4]. Studies with two experimental tumours ($HSDM_1$ mouse fibrosarcoma and VX_2 rabbit carcinoma) have indicated that excessive synthesis and secretion of prostaglandin E_2 (PGE_2) by the neoplastic cells is associated with and seems likely to be responsible for the hypercalcaemia observed in these tumour-bearing animals[2,5–8]. A similar hypercalcaemic syndrome occurs in some patients with cancer, is associated with excessive PGE_2 metabolite excretion in urine and is reversed at least in part by treatment with aspirin-like drugs[9,10]. Finally, intravenous infusion of PGE_2 in intact, unanaesthetised rats causes an increase of plasma calcium concentration[11]. The most straightforward interpretation of these findings is that PGE_2 is secreted by certain tumour cells into plasma in such quantity that the steady-state plasma concentration of PGE_2 is sufficiently high to stimulate osseous target cells to resorb bone. An alernative interpretation is that unmeasured intermediates in arachidonic acid metabolism or PGE_2 metabolites have sufficient bone resorption-stimulating activity to be the agent acting on bone cells. This hypothesis gains a degree of support from knowledge that some prostaglandin metabolites have longer half lives in plasma than PGE_2 itself[12]. We have now measured the biological activities of several endoperoxide analogues and PGE_2 metabolites in a bone culture assay system and compared their potencies with that of PGE_2.

The bone resorption-stimulating activities of three prostaglandin endoperoxide analogues are shown in Table 1. Azo-PG III, which stimulates platelet aggregation, release of 5-hydroxytryptamine and contraction of isolated rabbit aorta[13], did not stimulate bone resorption at doses up to 10 μg ml^{-1}. The other two analogues were only active;

Bone resorption was determined by measuring the release of calcium (^{40}Ca) from neonatal mouse calvaria in organ culture[2,14]. Medium total calcium concentration was measured with a Corning model 940 calcium analyser. Medium was Dulbecco's modified Eagle's medium supplemented either with bovine serum albumin (5 mg ml^{-1}) or heat-inactivated (60° C), 1 h horse serum (15% final concentration) and foetal calf serum (2.5% final concentration). Results were essentially the same in both kinds of medium. Treatment groups consisted of three or four bones each. Results given are mean values for medium total calcium ± s.e. at the end of 48 h of treatment with the compounds tested. U-44069 is (15S)-hydroxy-9α,11α-(epoxymethano)prosta-5Z,13E-dienoic acid (lot no. 12344-JMB-85). U-46619 is (15S)-hydroxy-11α,9α-(epoxymethano)prosta-5Z,13E-dienoic acid (lot no. 12344-JMB-109). Azo-PG III is (5Z, 9α, 11α, 13E, 15S)-9,11-azo-15-hydroxyprosta-5,13-dienoic acid[13]. The data in each experiment were subjected to an analysis of variance and s.e. was calculated from the residual error form of that analysis.

*Statistical difference from control mean $P < 0.001$.
†Statistical difference from control mean $P < 0.01$.
‡Statistical difference from control mean $P < 0.05$.

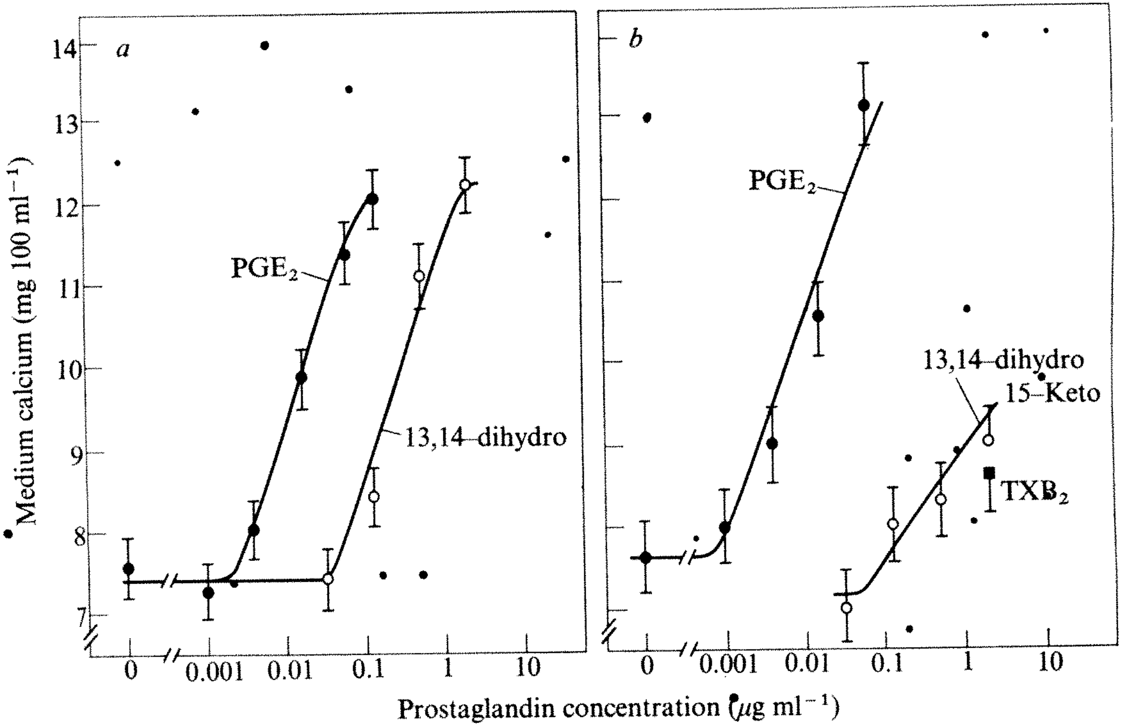

Fig. 1 Effects of increasing concentrations of PGE$_2$, 13,14-dihydro-PGE$_2$ and 13,14-dihydro-15-keto-PGE$_2$ on bone resorption in organ culture. Neonatal mouse calvaria were cultured and analysed as described in Table 1 except that both experiments were performed in heat-inactivated serum medium. Furthermore, the calvaria in these experiments were free floating instead of attached to cover slips as described in the original procedure[2, 14]. This modification simplifies the procedure without affecting the outcome. Each point gives the mean value for groups of three or four bones, and the vertical bars give the s.e. at the end of 48 h of treatment. The s.e. were calculated from an analysis of variance. *a*, PGE$_2$ (●); 13,14-dihydro-PGE$_2$ lot no. 12874-JHK-52A (○). *b*, PGE$_2$ (●); 13,14-dihydro-15-keto-PGE$_2$, lot no. 12277-JHK-122A (○); thromboxane B$_2$, lot no. 13066-RWJ-38A (■).

U-44069 and U-46619 were about 0.08% and 0.06%, respectively, as active PGE$_2$. None of these analogues was an effective antagonist of PGE$_2$-stimulated bone resorption (data not shown).

The bone absorption-stimulating activities of the PGE$_2$ metabolites 13,14-dihydro-PGE$_2$ and 13,14-dihydro-15-keto-PGE$_2$ were about 6.6% and 0.20%, respectively, as active as PGE$_2$ (Fig. 1). Thromboxane B$_2$ had even less biological activity than 13,14-dihydro-15-keto-PGE$_2$.

Our results indicate that the bone resorption-stimulating activity of PGE$_2$ is at least 1,000 times greater than that of the three prostaglandin endoperoxide analogues tested. PGE$_2$ is also about 15 times more potent than 13,14-dihydro-PGE$_2$ and about 500 times more potent than 13,14-dihydro-15-keto-PGE$_2$, although an accurate estimate of the potency of the latter metabolite was not possible because its dose–response curve was not parallel to that of PGE$_2$ (Fig. 1).

Because of their relatively low biological activities, if any of the metabolites were responsible for the bone resorption and hypercalcaemia seen in HSDM$_1$ and VX$_2$ tumour-bearing animals, the half lives of these compounds in plasma would need to be considerably greater than that of PGE$_2$, thus making it possible for them to accumulate to very high levels in plasma and extracellular fluid. The half life of PGE$_2$ is very short, probably less than 1 min[12]. The half life of native prostaglandin endoperoxides in aqueous media is about 5 min[12] and probably less in plasma although this has not been determined accurately. The half life in plasma of 13,14-dihydro-15-keto-PGE$_2$ is about 8 min and that of 13,14-dihydro-PGE$_2$ is not known[12]. Of the compounds tested, the most likely mediator of bone resorption, other than PGE$_2$, would be 13,14-dihydro-PGE$_2$ because its biological activity was the highest, about 6–7% of PGE$_2$. Unfortunately, no data are available on plasma concentrations of 13,14-dihydro-PGE$_2$ in control or tumour-bearing animals because there are no assays for this metabolite. We have reported that in tumour-bearing mice, plasma concentrations of 13,14-dihydro-15-keto-PGE$_2$ are considerably higher than corresponding levels of PGE$_2$[8]. This increment was not sufficiently large to cause hypercalcaemia in the mice because of the very low bone resorption-stimulating activity of 13,14-dihydro-15-keto-PGE$_2$. Seyberth *et al.* have also noted a greater increase in plasma 13,14-dihydro-15-keto-PGE$_2$ than PGE$_2$ in rabbits bearing the VX$_2$ carcinoma[15], and L. G. Raisz has observed (personal communication), using foetal rat long bones in culture, that 13,14-dihydro-PGE$_2$ and 13,14-dihydro-15-keto-PGE$_2$ are substantially less active stimulators of bone resorption than PGE$_2$.

Although our data do not rule out the possibility that prostaglandin endoperoxides or metabolites are the mediators of bone resorption and hypercalcaemia in the HSDM$_1$ and VX$_2$ model systems, we believe that the data available strongly suggest that PGE$_2$ is the mediator. Measurements of 13,14-dihydro-PGE$_2$ in plasma will provide more evidence when they are available.

Prostaglandins, endoperoxides and metabolites were given by Dr Udo Axen of the Upjohn Co., with the exception of azo-PG III which was supplied by Professor E. J. Corey of Harvard University. We thank Mrs E. A. Moore for statistical calculations. This investigation was supported in part by the USPHS.

Inhibition of masculine differentiation in male offspring of rabbits actively immunised against testosterone before pregnancy

ACTIVE immunisation of male rabbits with testosterone–protein conjugates results in the production of antibodies capable of neutralising the biologic activity of endogenous testosterone[1]. Due to the reduction of free, biologically active testosterone caused by almost total binding to antibodies the entry of this hormone into the target cells is inhibited, the metabolic clearance rate is decreased, the negative feedback to the hypothalamus is interrupted and pituitary gonadotropin release is increased. Thus, in spite of enormously elevated total plasma testosterone concentrations, atrophy of the prostate, paraprostate and seminal vesicles can be observed in suitably immunised male rabbits. In female rats actively immunised against testosterone Hillier *et al.*[2] also observed—despite significantly elevated total plasma testosterone concentrations —a considerable reduction of the free testosterone fraction and an elevation of FSH. Histological examination of these animals revealed development of polycystic ovaries, similar to those seen in the Stein–Leventhal syndrome in humans. These reports prompted us to study whether it is possible to fertilise female rabbits after active immunisation against testosterone, and whether in pregnancy the antibodies pass through the placenta in sufficient concentrations to neutralise the biologic activity of testosterone secreted by the foetal testes, thus selectively inhibiting the testosterone-dependent steps of male sex differentiation. We found inhibition of masculine differentiation in offspring of rabbits actively immunised against testosterone before pregnancy.

We immunised eight mature female rabbits by repeated subcutaneous injections of 2 mg testosterone-3-bovine serum albumin (T-3-BSA) dissolved in 1 ml of 0.9% saline at intervals of 2–6 weeks. For the first three injections, the antigen solution was emulsified in 1 ml of Freund's complete adjuvant. A control group of four animals was immunised against unconjugated bovine serum albumin (BSA) in an identical schedule. All animals injected with T-3-BSA developed highly specific antibodies against testosterone. Three months after beginning immunisation the titres ranged from 1 : 4,000 to 1 : 40,000 and increased after further booster injections. No antibodies to testosterone could be detected in the controls and their plasma testosterone concentrations (7–26 ng per 100 ml) were unaffected by the immunisation with BSA. In testosterone-immunised animals, however, the increase in antibody concentration was paralleled by a striking elevation of total plasma testosterone from an average of 12 ng per 100 ml before immunisation to 630–1,450 ng per 100 ml when anibody titres above 1 : 40,000 were reached. Regardless of these high testosterone levels, which exceed the normal range of male rabbits[1], we tried to mate these animals. After several fruitless attempts mating was successful in five of them. Altogether they gave birth to 19 males and 16 females. Throughout pregnancy the antibody titres varied from 1 : 15,000 to 1 : 40,000; the testosterone binding capacity at 0° C ranged from 130 to 220 μg per 100 ml. The four control animals produced 11 males and 16 females. Immediately after delivery all newborns were bled and blood was collected separately. The genital tract was fixed in Bouin's mixture, embedded in paraffin, cut transversely and stained with haematoxylin eosin.

In all neonates from animals immunised with testosterone high concentrations of antibodies against testosterone were found, with specificity and association constants identical to those in the maternal plasma. The testosterone binding capacity was about 40% of that of the corresponding mother. Plasma testosterone levels were very high with mean values of 1,600 ng per 100 ml in the females and 24,000 ng per 100 ml in males. The mean testosterone levels in the female and male control neonates, in contrast, were 15 and 18 ng per 100 ml, respectively, which resembled those of normal neonatal rabbits.

In spite of their enormously elevated testosterone levels, the experimental female neonates showed normal female sex differentiation; the males, however, revealed genital malformations which can be traced back to the inactivation of testosterone by antibody binding, resulting in feminisation of internal and external genitalia. The most striking finding was the underdeveloped accessory sexual glands. In most animals the prostate and paraprostate were totally absent and the vesicular glands were reduced to rudimentary buds (Fig. 1). The bulbo-urethral glands, which in males are normally more extensively developed than in females, showed the extent of female glands only. Seminal vesicles were present in all experimental males; however, in most of them they were less developed than in normal neonates. The Wolffian ducts were severely affected and were at the point of regression (Fig. 2). The epithelium was irregular and flat, the basal membrane had disappeared and the surrounding mesenchyme penetrated into the epithelium. Pycnosis, chromatolysis and other signs of imminent cell death predominated. The phallus of most males immunologically deprived of testosterone was also feminine (Fig. 3). The urethra corresponded to the female sinus urogenitalis rather than to the urethra of normal males. The corpus fibrosum was reduced to the

normal extent for females. As in females, the lamina glandaris was open ventrally, the urethra was located eccentrically, protruding into the perineum, and severe hypospadias could be observed. Despite these distinct manifestations of testosterone deficiency we never observed alternative development of female gonoducts. As in normal males the Müllerian ducts were completely inhibited. No abnormalities were detected in the testes, so withdrawal of testosterone as from the beginning of foetal development did not influence the gonadal differentiation. Microscopic examination of the control litters revealed normal sex differentiation in both sexes. The histological pictures were indistinguishable from those of normal female and male neonatal rabbits, respectively.

Our experiments indicate that hormones, which are essential for normal foetal development, can be neutralised in the foetuses by their respective antibodies raised in the mother, provided that the immunisation does not interfere with fertilisation. In rabbits active immunisation against testosterone does not preclude pregnancy. After passage of the placenta, the antibodies inhibit the entry of testosterone produced by the foetal testes into the cells of the developing target organs. In contrast to the experiments of Jost[3], who deprived male foetuses totally of testicular activity by castration *in utero*, our experiments resulted in the selective suppression of the androgenic effects of the foetal testes, leaving that testicular factor intact which controls Müllerian duct inhibition. Thus, with respect to the foetal genital tract the effects of maternal immunisation against testosterone are comparable to those of blocking the foetal androgens by treating the pregnant mothers with cyproterone acetate, as described by Neumann *et al.*[4] The 1,000-fold elevation of plasma testosterone in the male offspring of testosterone-immunised female rabbits suggests, however, that the antibodies exhibit additional important effects on foetal testosterone metabolism and regulation.

Vitamin A deprivation and *Drosophila* photopigments

VITAMIN A deprivation causes a profound reduction in visual sensitivity and photopigment concentration in the eyes of both vertebrates and invertebrates[1,2]. In vertebrates vitamin A deprivation results in degeneration of photoreceptor cells[3] and decreases the number of intramembrane particles visualised in the disks of rod outer segments by freeze-fracture electron microscopy[4]. This and other evidence[5] suggests that these particles represent rhodopsin molecules. Invertebrate photoreceptors have similar, 8-nm intramembrane particles in the stacked microvilli which form their light-sensitive rhabdomeres[6,7]. The number of particles is comparable to the number of pigment molecules present[8] and is dependent on the state of light adaptation[9]. We describe here a study of the effects of vitamin A deprivation on the fine structure, photopigment content, and sensitivity of *Drosophila* photoreceptors. The results support the hypothesis that most of the intramembrane particles in invertebrate rhabdomeres, like those in vertebrate photoreceptors, are rhodopsin molecules.

D. melanogaster (Canton-Special strain) were deprived of vitamin A by raising sterilised eggs on Sang's synthetic medium C (ref. 10); control flies were reared identically except that β-carotene 1.25 mg ml^{-1} was added to the medium. White-eyed mutants (*w*) were employed in some experiments to eliminate screening pigments which interfere with spectrophotometric measurements. Fly heads were bisected, fixed for 2 h at 21 °C in half-strength fixative[11], and washed in cacodylate buffer. Preparations for conventional electron microscopy were postfixed in osmium tetroxide, embedded in epoxy plastic, sectioned, and stained with

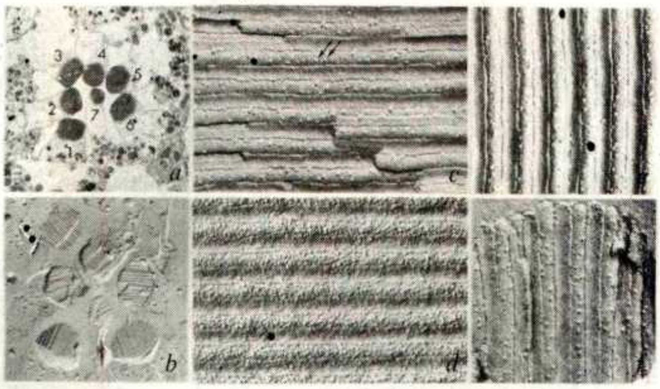

Fig. 1 Electron micrographs of *Drosophila* photoreceptors: *a*, tangential section through the central portion of an ommatidium in a vitamin A-deprived fly, showing cells R1–R6 and R7. The size and arrangement of the retinular cells and their rhabdomeres are normal (×2,400); *b*, freeze-fracture view similar to the above, demonstrating fracture faces in a vitamin A-deprived fly and the ability of the technique to demonstrate specific retinular cells (×4,000); *c*, high-magnification freeze-fracture view of rhabdomeric membranes of a peripheral photoreceptor in a vitamin A-deprived specimen—8-nm intramembrane particles (arrows) are very few in number (×43,000); *d*, freeze-fracture view of control rhabdomeric membranes, which are heavily studded with particles (×43,000); *e*, high-magnification photomicrograph of a cell R7 rhabdomere from a deprived animal, demonstrating a paucity of particles (×43,000); *f*, membrane fracture faces of a cell R8 from a deprived fly, showing a reduced intramembrane particle density (×43,000).

lead citrate. Freeze-fracture specimens were equilibrated for 8 h with 25% glycerol in *Drosophila* saline, freeze-fractured and etched for 1 min in a Balzers apparatus, and replicated by platinum and carbon shadowing. Specimens were examined with a Philips EM 301 and measurements made on prints at a magnification of 100,000×. Visual pigment content in homogenates prepared from exactly 100 heads each was assayed for light-induced absorbance changes in a dual-wavelength spectrophotometer[12]. Visual sensitivity was measured by determining the intensity of 470-nm light needed to elicit a criterion electroretinogram (ERG) response[12] of 5 mV.

Vitamin A-deprived *Drosophila* retinas appear normal in low-power electron micrographs (Fig. 1*a*, *b*) and rhabdomeric dimensions fall within the normal range. The number of 8-nm intramembrane particles in rhabdomeric microvilli, however, is decreased about fourfold in comparison with controls (Fig. 1*c*, *d*, Table 1). Spectrophotometric measurements reveal a greater than 70-fold reduction in photopigment level (Fig. 2, Table 1). Correspondingly, visual sensitivity as measured by the ERG is reduced approximately 80-fold by vitamin A deprivation (Table 1).

The normal size and shape of the rhabdomeric microvilli in vitamin A-deprived *Drosophila* show that a full complement of rhodopsin is not required for structural integrity of the photoreceptor membrane, a finding similar to that in *Aedes*[13] but contrasting with that in vertebrate rods[3] and moth photoreceptors[14]. The nature of the intramembrane particles remaining after vitamin A deprivation is unknown; because the reduction in rhodopsin measured spectrophotometrically or physiologically is much larger than the reduction in particle density, it is unlikely that the persisting particles represent rhodopsin molecules. The discrepancy of results obtained by the three techniques could be explained if some of the particles are not photopigments or if they are opsin molecules lacking chromophores. Nevertheless, the evidence indicates that the large majority of the 8-nm particles in the rhabdomeric membranes of normally reared flies are rhodopsin molecules.

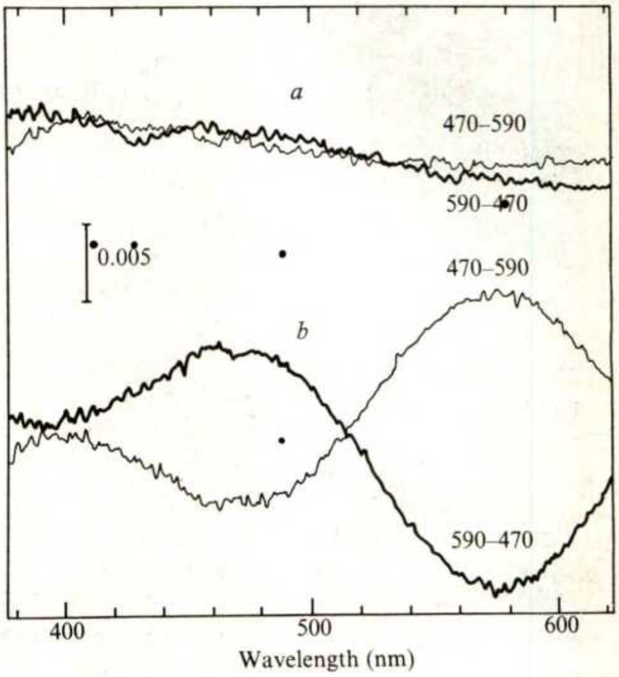

Fig. 2 Absorption spectra changes for *a*, vitamin A-deprived flies and *b*, control flies. The ordinate is the difference between the absorbances after 10 s actinic irradiations presented successively at 470 nm (2.7 mW cm^{-2}) and 590 nm (2.3 mW cm^{-2}; thin lines) or in the opposite order (thick lines).

Each subunit or ommatidium of the *Drosophila* compound eye contains eight photoreceptors which constitute three distinct classes, each with a different photopigment[12]. These three types correspond morphologically to the peripheral photoreceptors, cells R1–R6, which are blue receptors; the upper-central cell, R7, which is an ultraviolet receptor; and the lower-central cell, R8, which is a blue receptor with a different pigment from that in cells R1–R6. The preponderance of R1–R6 cell types in the retina

Table 1 Effect of vitamin A deprivation on the density of intramembrane particles, light-induced absorbance change, and electroretinogram sensitivity in *Drosophila*

	Vitamin A-deprived	Control	Deprived Control
Intramembrane particle density (particles per μm^2)*	1030 ± 31 ($n = 27$)	4214 ± 163 ($n = 6$)	0.24 ± 0.01
Light-induced absorbance change (ΔA)	< 0.0002 ($n = 2$)	0.015 ± 0.002 ($n = 2$)	< 0.01
Electroretinogram sensitivity (mV μW^{-1} cm^{-2})*	0.42 ± 0.07 ($n = 5$)	32 ± 5 ($n = 5$)	0.013 ± 0.003

Intramembrane particle densities were determined from counts of the 8-nm particles on rhabdomeric 'P' fracture faces and from areal measurements made with a Wang 600 planimetric computer. No corrections were made for the curvature of microvillar surfaces. Data from white-eyed and normally pigmented flies were not significantly different and were combined. Light-induced absorbance changes were measured with the sensitive dual-wavelength mode of the spectrophotometer at 470 and 580 nm; 10 s actinic irradiations were provided alternately at 470 nm (2.7 mW cm^{-2}) and 590 nm (2.3 mW cm^{-2}). Visual sensitivity was measured for a criterion electroretinogram response of 5 mV to 470 nm light. Data are given as means with standard errors of means; n is respectively the number of rhabdomeres scored, of pigment preparations scanned, and of flies studied.

*Difference significant at $P < 0.001$.

usually masks the contribution of R7 and R8 cells to spectrophotometric and ERG measurements, and thus prevents the determination of the chromophore in these cells. The reduction of intramembrane particles by vitamin A deprivation in all three receptor classes (Fig. 1*e*, *f*, Table 1) suggests, however, that the three spectrally distinct photopigments all use retinal (or its derivatives) as a chromophore. This result is consistent with other evidence[15] that the ultraviolet-sensitive photopigments of flies are retinal-based.

Storage of cannabinoids by *Arctia caja* and *Zonocerus elegans* fed on chemically distinct strains of *Cannabis sativa*

THE larvae of the warningly coloured tiger moth *Arctia caja* (L.) (Lepidoptera) and the grasshopper *Zonocerus elegans* (Thunberg) (Acridoidea) are polyphagous feeders with a predilection for poisonous food plants. These species can sequester and store various secondary plant substances such as cardiac glycosides and pyrrolizidine alkaloids[1,2], which presumably function as predator deterrents. We report here that cannabinoids ingested with the leaves of *Cannabis sativa* L. are also stored by both insects.

There is good evidence that *C. sativa* contains at least two chemical races or strains, one rich in the psychoactive substance Δ-1-tetrahydrocannabinol (THC) and the other in the inactive cannabidiol (CBD)[3], and accordingly one of each type was used in our work.

A. caja larvae, derived from a single egg batch from a wild female caught at Ashton Wold, were allowed to feed freely either on a Mexican THC-rich strain (referred to as THC strain) or a Turkish CBD-rich strain (referred to as CBD strain), with no alternative food offered. Leaves from matched shoots of both strains were taken for analysis as controls. Feeding continued for 44 d at 24 °C and 50% relative humidity. Another batch of larvae was reared to the third instar on the CBD strain, then transferred to the THC strain. Controls were fed on *Senecio jacobaea* L. Only nine wild caught *Zonocerus elegans* nymphs (from Nigeria, where they were feeding on cassava) were available. Because we found the Mexican strain of *Cannabis* had proved lethal for hoppers of *Schistocerca gregaria* (Forsk.) we allowed *Z. elegans* to feed on both strains indiscriminately. They showed no preference but fed sparingly. One specimen died and the rest were killed after 6 week continuous feeding on *Cannabis*. For the last 3 d before analysis the diet was changed to grass to empty the gut of cannabinoids. Eight whole insects, four exuviae and a sample of frass were analysed.

The *A. caja* larvae fed on THC strain were stunted (Fig. 1) and did not survive beyond the third instar. Those fed on the CBD strain developed more slowly than the controls, but pupated successfully after 7–8 weeks of larval life.

About 30% of larvae reared to the third instar on CBD strain and then transferred to the THC strain developed and pupated successfully. Subsequently, further attempts were made to rear larvae on the THC strain, and on one occasion four specimens reached the fifth instar after 9 months' continuous feeding, and, of these, one pupated and the female which emerged mated and laid fertile eggs.

The vegetative leaves of the Mexican strain contained 19.3 mg of THC per g dry weight, while those of the Turkish strain contained 10.2 mg of CBD per g dry weight. Thus the greater toxicity of the Mexican strain may have been due to greater toxicity of THC or simply to a greater absolute amount of cannabinoid: other differences between the two types may contribute to the more lethal effect of the Mexican THC strain.

The larvae (starved for 24 h before analysis), their frass, exuviae and pupae were examined for cannabinoids. Insect samples were extracted for 18 h with ethanol at room temperature and the extracts were assayed as described before[4]. Quantitative identification of cannabinoids was checked by thin-layer chromatography[5]. The residue was heated under reflux with 0.1 N NCl for 1 h and then

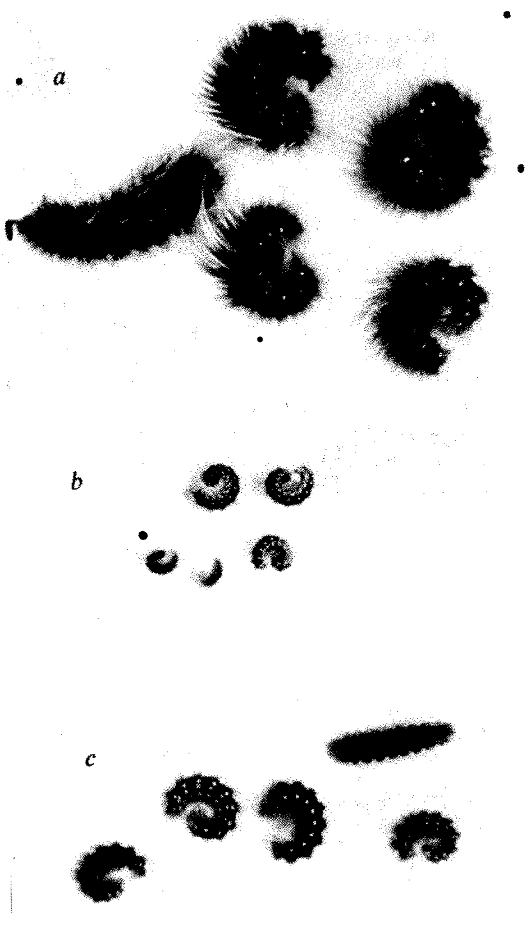

Fig. 1 Larvae reared for *a*, 32 d on ragwort (*Senecio jacobaea*); *b*, 32 d on the THC-rich strain of *Cannabis*; and *c*, 32 d on the CBD-rich strain of *Cannabis*.

Table 1 Cannabinoid contents (mg per g fresh weight) of *Arctia caja* fed on *Cannabis sativa**

	Feeding regime		
	CBD type throughout larval growth	CBD type to 3rd instar, and then THC type	THC type to death (3rd instar)

NE, not examined.

extracted with diethyl ether. This extract was also examined as above.

Table 1 shows that specimens reared throughout larval growth on CBD strain contained only traces of CBD, insufficient for quantitative analysis. Acid hydrolysis of the residue released a trace of a compound which gave a positive colour reaction for cannabinoids but did not correspond to any available standards on gas chromatography. Such traces were also found in the pupae and may represent a metabolite of CBD, present as a glucoside. CBD, as the acid, in which form it appears in the plant, was present in the exuviae (cast skins) at a concentration of 0.0012 mg per exuvia. On the other hand, larvae reared to the third instar on the CBD strain then transferred to the THC strain, stored more CBD per insect (0.01 mg) in the fifth instar than those fed solely on the CBD strain, and in addition each contained 0.07 mg of THC. This was also present mainly as the acid, but some decarboxylated THC was identified.

The exuviae of insects reared exclusively on the THC strain until death contained relatively high concentrations of THC acid. Thus, measured as mg of cannabinoid per g of insect material, the exuviae of insects reared on the THC strain contained more than ten times as much cannabinoid as those feeding on the CBD strain. Those reared to the third instar on the CBD strain and then switched to the THC strain contained 25 times as much.

In both sets of larvae at least 80% of the cannabinoids recovered was found in the relatively small sample of frass analysed (Table 1). This shows that they excrete much more cannabinoid than they store; however the concentration in the frass was much less than that in the plant material, which was the sole article of diet, so that most of the cannabinoid eaten must have been metabolised.

Most of the cannabinoid recovered from *Z. elegans* (Table 2) occurred in the frass. The weight of THC in the whole insect was remarkably similar to that in full grown *A. caja* larvae, but a much smaller proportion was stored in the integument. CBD was lacking in both the insects and their exuviae, although it occurred in the frass, thus indicating that *Z. elegans* can metabolise this compound efficiently.

The most striking aspect of the storage of THC by *A. caja* is the relatively large amounts concentrated in the cuticle. Thus the insect can rid itself of much of the toxic material not voided in the frass, but accumulates it between moults at a site where it could function as a 'predator deterrent'. Mice, which are voracious feeders on larval Lepidoptera, show a reduction of spontaneous activity when given an oral dose of 0.013–0.025 mg of pure THC (J. Pickens, unpublished). Thus, one larva containing 0.07 mg THC would be above the threshold dose for pharmacological activity. Although the accumulation of toxins in the cuticle has not been noted before, it may be a widespread method for the storage of deterrent secondary plant substances, especially in aposematic larvae which are followed by a cryptic adult stage[6].

When we offered newly hatched *A. caja* larvae (20 trials) a choice of leaves from both strains of the plant (matched for size, age and position on the stem) they showed a definite preference for the Mexican strain. This may be due to factors unconnected with the type and concentration of cannabinoids, but should these compounds exert a fatal fascination for tiger caterpillars it suggests another subtle system of insect control by plants.

Table 2 Cannabinoid contents of *Zonocerus elegans* fed on *C. sativa*

	THC content*	CBD content*
Whole insect (mg per insect)	0.06	0
Exuviae (mg per g dry weight)	0.006	0
Frass (mg per g dry weight)	2.95	0.97

*No additional cannabinoid was released by acid hydrolysis.

Our results demonstrate the versatility of moth and grasshopper in dealing with poisonous plant substances encountered during feeding. Both are preadapted to the storage of cannabinoids, for *C. sativa* has not been recorded as a food plant in nature. Because of widespread cultivation of *C. sativa* the ranges of the plant and *A. caja* now overlap. Furthermore, both store the more toxic THC rather than the relatively innocuous CBD. This is reminiscent of the aposematic butterfly *Danaus plexippus* (L.) and grasshopper *Poekilocerus bufonius* (Klug) which also store the more active cardiac glycosides[7] ingested with their food plants.

We thank Dr Elizabeth Bernays for the gift of living *Zonocerus*.

Nature of recombinants produced by the RecBC and the RecF pathways in *Escherichia coli*

BASED on analysis of various recombination deficient mutants, at least three different pathways of chromosomal recombination have been suggested in *E. coli* K12: the RecBC, the RecF and the RecE pathways[1-3]. Our present knowledge of initial and final DNA structures and of the intervening events is very limited. Only some of the genes controlling each pathway have been identified[3,4]; the products of a few of these have been isolated and characterised[5-10]; little is known about the specific steps at which these products participate in the respective pathways. The role of exonuclease V, the product of the *recB* and *recC* genes, has been studied[11-15]. Recipients deficient in this enzyme give greatly reduced yields of viable recombinants[11], but support certain types of recombinational events with relatively high efficiency[12,13,15]. ExoV has thus been considered to be more important in determining viability of the recombinant cells than in the recombinational process itself. It has been suggested, on the basis of transformation and transduction experiments, that the recombinant products of the RecBC and the RecF pathways may be structurally different[16,17]. We present here results from conjugation crosses of *E. coli* K12 which demonstrate that the viable recombinants produced by the RecBC and the RecF pathways are significantly different in terms of the density of genetic exchanges present in them. A preliminary account of this work has already been presented[18].

A simple mathematical formulation of *E. coli* conjugation system[19] shows that the recombinational process in this system can be visualised as consisting of two operationally separable parts: (1) the initiation of the recombinational process at randomly distributed points on the chromosome, and (2) the development around these points of short regions of recombination (RRs), each of which may contain several genetic exchanges. Increase in the probability of initiation of the RRs is reflected in increased values of two-point recombination frequencies (R1) between pairs of markers, while increase in the mean number of exchanges per RR, is reflected in increased values of R2(1), which is a measure of the frequency of additional exchanges close to a selected exchange (Fig. 1). A comparison of R1 and R2(1) values in recombinants produced by the different recombinational pathways can thus give information about the differences present in the final products of these pathways and about the earlier events.

MD1763, a *pyrA* derivative of HfrH was mated with an *ara*, *thr*, *str-r*, F⁻ recipient, AB1157 and its *recB recC*, *recB recC sbcB*, and *recF* derivatives (Table 1). Selection was made for *ara*⁺ *str-r*, *ara*⁺ *pyrA*⁺ *str-r* and *ara*⁺ *pyrA*⁺ *thr*⁺ *str-r* recombinant types. The values of R1 and R2(1) calculated from these (Table 2) are strongly dependent on the recombinational pathways functioning in the recipients. It seems that the recombinational process controlled by the RecF pathway involves a higher density of exchange clusters along the chromosomal length and a higher number of recombinational exchanges per cluster as compared to the RecBC pathway.

The markers involved in the above intergenic cross are comparatively widely spaced, each of the two intervals (1 and 2) measuring a little more than half a minute on the standard genetic map of *E. coli* K12 (ref. 20). To see whether similar pathway-dependent effects are present in recombination involving closely spaced markers, two-point crosses involving markers, (1) within a single gene (*araC*), and (2) in two neighbouring genes (*araB* and *araC*) of a single operon, were performed for all the above-mentioned recipient backgrounds. R1 values were determined in each case (Table 3), and the effect of mutations in the RecBC or the RecF pathway on R1 values for closely spaced markers is essentially similar to that for widely spaced markers (Table 2).

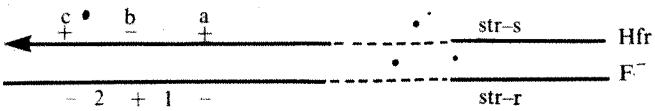

Fig. 1 Configuration of a typical three-point cross; R1 is the two-point recombination frequency in region 1 and is the number of $a^+b^+str\text{-}r$ recombinants per $a^+str\text{-}r$ recombinant. R2(1) is the frequency of recombination in region 2 in the subpopulation selected for recombination in region 1 and is given by the number of $a^+b^+c^+str\text{-}r$ recombinants per $a^+b^+str\text{-}r$ recombinant.

Table 2 Conjugational crosses between MD1763 donor strain and different recipient strains

Recipient strains	R1	R2(1)
AB1157	0.062±0.017	0.16±0.04
AB2470C	0.24 ±0.04	0.12±0.04
JC7623	0.24 ±0.05	0.25±0.05
JC9239	0.055±0.015	0.11±0.03

Conjugation experiments were performed as follows: exponentially growing cultures (2–4 × 10⁸ cells per ml) of donor and recipient cells were mixed in the ratio 1:5 and incubated for 5 min, then the mating mixtures were diluted 1:50 in liquid BT 8 nutrient broth containing tryptone) and allowed to mate for another 55 min with gentle shaking. The mating mixtures were then diluted 1:1 in BT containing 200 μg per ml⁻¹ streptomycin, blended and incubated with shaking for 4 h, then plated on prewarmed selection plates[14], spread with 0.7% topping agar and incubated for 40 h before counting the number of recombinant colonies. All operations were performed at 37°C. The results are averages of at least three experiments. The above cross is similar to the typical three-point cross shown in Fig. 1, with *ara-14*, *pyrA53* and *thr-1* representing markers *a*, *b* and *c*, respectively. Both R1 and R2(1) values are highest in JC7623, which is expected to produce most of its viable recombinants via the RecF pathway. The lowest values are obtained in JC9239, which lacks the RecF pathway and is mostly dependent on the RecBC pathway for recombinant production. The wild type AB1157 gives intermediate values for these frequencies, while AB2470C, which lacks exoV gives an R1 value comparable to JC7623 and an R2(1) value, somewhat lower than the wild type.

Table 1 *E. coli* K12 strains used in this study

Strains	Rec genotype *recB*	*recC*	*recF*	*sbcB*	Other markers	Sex	Source or ref.
AB1157	+	+	+	+	*thi-1*, *thr-1*, *leu-6*, *lacY1*, *mtl-1*, *xyl-5*, *ara-14*, *galK2*, *his-4*, *proA2*, *argE3*, *tsx-33*, *sup-37* (amber), *str-31*	F⁻	A. J. Clark
AB2470C	21	22	+	+	Same as AB1157	F⁻	J. Tomizawa
JC7623	21	22	+	15	Same as AB1157	F⁻	A. J. Clark
JC9239	+	+	143	+	Same as AB1157	F⁻	A. J. Clark
MD1763	+	+	+	+	*pyrA53*, *thi*	HfrH	19
MD2116	+	+	+	+	*araB113*, *trpR1*, *dra-2*	HfrH	This study
MD2121	+	+	+	+	*araC191*, *trpR1*, *dra-2*	HfrH	This study

MD2116 is an *araB* and MD2121 is an *araC* derivative of WP1767 (ref. 19); *araB* and *araC* mutations were isolated after mutagenesis with 2-aminopurine.

The comparable (three to fourfold) increase in R1 in AB2470C and JC7623 indicates that in the absence of exoV, the probability of initiating RR in a given chromosomal length increases. As most current models of recombination[21,22] postulate the presence of single-stranded breaks (nicks) in DNA as an essential prerequisite for initiating the recombinational process, it is reasonable to infer that, in the absence of exoV, the density of such nicks is higher. This is consistent with the suggestion[23] that *recB*$^+$ *recC*$^+$ gene products are involved in the repair of chain breaks that arise during cell growth. The alternative possibility that exoV has no effect on the mean density or distribution of RR and that the increase in R1 values is simply a reflection of higher selective survival (for some unknown reason) of the recombinant subpopulation with higher number of RR seems rather improbable: it would be difficult to understand why AB2470C and JC7623, which give widely different yields of viable recombinants, should give comparable increases in R1 values.

Table 3 Two-point recombination frequencies (R1) between pair of *ara* markers in different recipient strains

Recipient strains	Donor strains	
(*ara-14*)	MD2116 (*araB113*)	MD2121 (*araC191*)
AB1157	0.0095±0.0012	0.00047±0.00010
AB2470C	0.0253±0.0080	0.00138±0.00020
JC7623	0.0278±0.0060	0.00161±0.00003
JC9239	0.0090±0.0026	0.00031±0.00005

The experimental procedures were similar to those in Table 2. The order of *ara* mutations was *pyrA53 araB113 araC191 ara-14 leu*. To calculate the frequency of recombination between different *ara* markers, the nearby *leu* was used as a reference marker. The frequencies given represent ratios of *ara*$^+$ *str-r* recombinants to *leu*$^+$ *str-r* recombinants produced in the respective crosses and are averages of at least three independent experiments in each case.

The considerably higher value of R2(1) in JC7623 than in AB2470C indicates that the deficiency of exonuclease I increases the mean number of exchanges per RR which may be due either to an increased exchange density within these regions of recombination or to an increase in the mean length of these regions or both. The second alternative more easily explains the improved recovery of recombinants in the exoI deficient *recB recC* cells, and is consistent with results in P1-mediated transduction crosses[24]. These observations support a model (manuscript in preparation) which postulates that the RecBC pathway preferentially promotes integration of double-stranded donor DNA segments which may have short single-stranded ends, whereas the RecF pathway mostly promotes integration of single-stranded donor segments.

We thank A. J. Clark and J. Tomizawa for supplying *E. coli* strains.

High-LET radiations induce a large proportion of non-rejoining DNA breaks

THE mechanisms by which mammalian cells are killed by ionising radiation have not been explained at the molecular level and radiations with a high linear energy transfer (LET) can provide an important tool for investing these mechanisms. High-LET radiations, such as neutrons, π-mesons and low-energy heavy ions are known to kill bacteria[1,2], yeast[3,4], and mammalian cells *in vitro*[5–9] more efficiently per unit dose than radiations with diffuse patterns of ionization, or low-LETs, such as γ or X rays. Other radiobiological phenomena associated with high-LET radiations are a reduced effect of chemical modifiers, for example, oxygen[10], on cellular radiation sensitivity and reduction or loss of cellular ability to recover from radiation damage between split radiation doses[5,8]. Because of these and other attributes, including the favourable depth–dose distribution of heavy ions and π-mesons, high-LET radiations are being actively considered for use in cancer radiation therapy[11,12], and a thorough understanding of their biological effects is necessary for them to be used to advantage clinically. We report here that, over an LET range of 1–1953 keV μm^{-1}, there is an excellent correlation between the efficiency of exponential (single-hit) cell killing and the induction of non-rejoining DNA strand breaks, as measured on alkaline sucrose gradients. This correlation implies that non-rejoined breaks are a cause of cell death.

We measured DNA strand break induction and rejoining in Chinese hamster V79 S171 cells[13]. X rays (300 kVp, 1.6 mm Cu h.v.l.) and low-energy heavy ions from the Lawrence Berkeley Laboratory 88-inch cyclotron and heavy-ion linear accelerator provided radiations with the various LETs used (Table 1).

Table 1 Heavy ion parameters

Ion	Energy (MeV a.m.u.$^{-1}$)	LET* (keV μm^{-1})
Proton	4.0	9.4
Proton	1.15	27
^{9}Be	4.0	151
^{12}C	3.8	332
^{20}Ne	3.8	827
^{40}A†	3.9	1953
^{40}A	1.5	2900

*LET in water.
†Three experiments, with ion energies of 4.6, 4.2 and 3.0 MeV a.m.u.$^{-1}$ are grouped here.

As LET increased from 1 keV μm^{-1} with X rays to 1953 keV μm^{-1} with ^{40}A ions, DNA strand break induction decreased from $2.67 \pm 0.14 \times 10^{-4}$ to $0.48 \pm 0.03 \times 10^{-4}$ breaks per 10^8 daltons per rad (Fig. 1*a*). The percentage of these breaks that did not rejoin in post-irradiation incubation of $8\frac{1}{2}$ h or more, however, increased with LET from 1.4±0.4% for X rays to 17.9±1.5% at 1953 keV μm^{-1} (Fig. 1*b*).

The data of Fig. 1*a* and *b* were combined to obtain the efficiency for the induction of non-rejoining breaks, normalised to the value obtained for X rays. This yielded a relative efficiency for non-rejoining break induction as a function of LET (Fig. 2). The peaked response obtained is similar to that found for killing of some strains of bacteria[1,2] and yeast[3,4], for induction of mutations in yeast[14], for killing of mammalian cells *in vitro*[5–], and for induction of chromosome aberrations in mammalian cells *in vitro*[7].

Killing of mammalian cells by ionising radiation can be described in terms of two classes of radiation interactions[15–17]: an irreversible lethal class, which follows single-hit kinetics and leads to an initially non-zero, negative slope on log survival against dose curves; and a sub-lethal class, which may or may not be reversible ad which leads to a sigmoidal survival curve. Most of the high-LET, mammalian cell studies cited above demonstrate that the single-hit component of cell killing predominates for high-LET radiations, yielding linear survival curves on log plots.

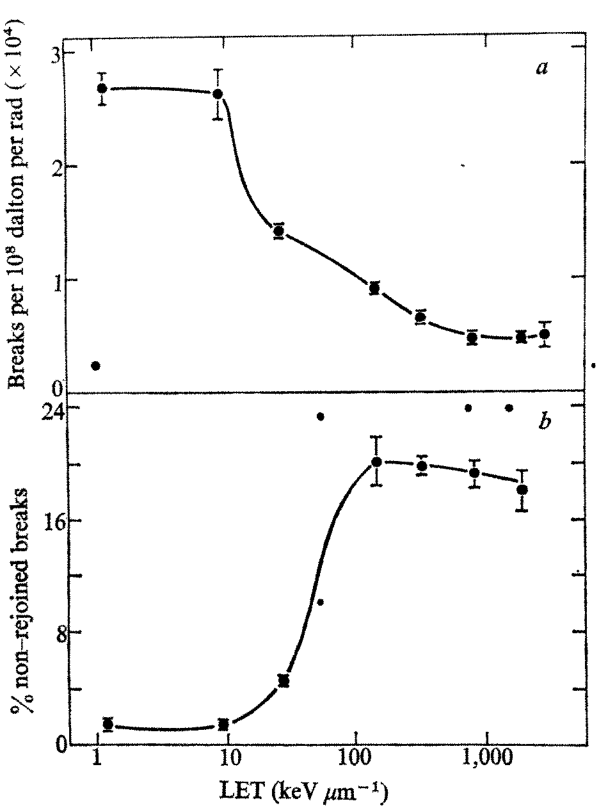

Fig. 1 Induction of DNA strand breaks by X ray and heavy ion irradiation. V79 S171 cells were grown as monolayers on glass dishes and labelled with ^{14}C-thymidine (0.07 μCi ml^{-1}, 57 Ci mol^{-1}) for 12–14 h. They were then exposed to X rays or to the heavy ion radiations indicated in Table 1, and allowed to grow for 0–12 h before collecting for gradient analysis. To eliminate the need for alkaline sucrose gradient analysis immediately, cells were frozen and gradient analysis was performed up to 1 month later. For collecting, cells were rinsed twice with citrate saline (0.75 M sodium citrate, 0.075 M sodium chloride) and 0.8 ml of citrate saline was added to cover the monolayer. The entire dish was then pressed against a methanol-coated thin aluminium plate resting on powdered dry ice. This gave very rapid freezing (within 2–3 s) of the cell monolayer and the citrate–saline solution that covered it. Dishes were placed in deep freeze (−76 °C) for storage. When gradient analysis was to be performed, cell dishes were thawed in 3–4 min at room temperature. Cells were detached from the surface by gentle repipetting of the citrate–saline solution covering them, and then an equal volume of lysis solution, consisting of 0.5 M NaOH, 0.02 M Na_2-EDTA and 0.1% NP-40 (non-ionic detergent) was added. Lysis was allowed to proceed for 1½–2 h, and 1.0 ml of the lysate was transferred to the top of an alkaline sucrose gradient. Transfer was performed with a wide-bore pipette tip connected by a Tygon tube to a motor-driven syringe. Alkaline sucrose gradients (5–20%) were formed from 5% sucrose containing 0.1 M NaOH, 0.9 M NaCl and 0.01 M Na_2-EDTA (*p*H 12.15) and 20% sucrose containing 0.15 M NaOH, 0.85 M NaCl and 0.1 M Na_2-EDTA (*p*H 11.20). Thirty min after the cell lysate was transferred, gradients were centrifuged at 19,700 r.p.m. in an SW 27 rotor for times that brought the peak of the DNA profiles approximately 75% of the distance down the tube. Thirty fractions per gradient were collected by puncturing the tube bottom, the radioactivity per fraction was counted, and molecular weights (weight average and number average) and the numbers of DNA breaks were calculated as before[27,28], using phage T4 DNA as a molecular weight standard. A number average molecular weight of approximately 2×10^8 was calculated for DNA from unirradiated V79 cells. *a*, Efficiency of induction of strand breaks. Cells were irradiated at 4 °C with doses between 3 and 45 krad and were analysed for strand breaks without subsequent incubation at 37 °C. *b*, Percentage of non-rejoining breaks, that is, DNA breaks in (*a*) that did not rejoin in 8½ h or more of post-irradiation incubation at 37 °C. These percentages were independent of dose (data not shown). Rejoining data were not obtained for the 2,900 keV μm^{-1} ^{40}A ion irradiations.

Todd[18,19] analysed extensive high-LET survival data for T-1 human kidney cells in terms of such single-hit and sigmoidal components. Relative efficiencies for single-hit killing, equivalent to relative efficiencies measured at high survival levels, can be calculated from Todd's data. These are in excellent agreement with the relative efficiencies for non-rejoining DNA break induction found here (Fig. 2). These non-rejoining break data are also in close agreement with other high-LET data for single-hit killing of Chang human liver cells[19] and Chinese hamster CH2B2 cells[7] (not shown). The implication is that non-rejoining DNA breaks cause single-hit, irreversible cell death. If this is true, then non-rejoining breaks would constitute the predominant lethal lesion for high-LET radiations. At low-LETs, their contribution to cell killing would depend upon such factors as dose and dose rate, becoming relatively more important, compared to sublethal damage, as dose or dose rate was reduced.

There is evidence to support the contention that non-rejoining DNA breaks might result in cell death. Some *Escherichia coli* mutants that cannot rejoin X-ray-induced DNA breaks exhibit extreme X-ray sensitivity[20]. Furthermore, when ^{125}I is incorporated into mammalian DNA, its decay induces a high percentage of DNA breaks that are not rejoined[21], whereas breaks induced by ^{3}H or X rays are rejoined[21,22]. ^{125}I has been shown to be more lethal per decay than ^{3}H and more lethal per rad than X rays[23]. Also, the size of daughter DNA synthesised in cells irradiated with either high- or low-LET radiations does not exceed the size of the parental DNA in up to 12 h of post-irradiation synthesis (our work, in preparation). This indicates that non-rejoining breaks in the parental DNA serve as permanent barriers to synthesis of daughter DNA and again suggests that non-rejoining DNA breaks are lethal lesions.

The alkaline sucrose gradient technique used here detects three classes of DNA damage as breaks: single-strand breaks, double-strand breaks, and alkali-labile lesions. Thus, it is not possible to determine the exact nature of the non-rejoining breaks detected in this study. But, a peaked response with LET for the induction of any test effect, such as we found for non-rejoining breaks, implies that two or more radiation–target interactions are required to induce the effect[24]. This type of induction kinetics is consistent with the induction of DNA double-strand breaks. There is also direct evidence that high-LET radiations induce double-strand breaks more efficiently in phage[25] and mammalian[26] DNA than do low-LET radiations. In addition, there is experimental evidence that non-rejoining DNA breaks induced by γ rays are actually double-strand breaks[29]. Thus, it seems likely that DNA double-strand breaks comprise at least part of the non-rejoining breaks seen here in alkali after high-LET radiations. Other possibilities should not be excluded, however. For example, it might not be

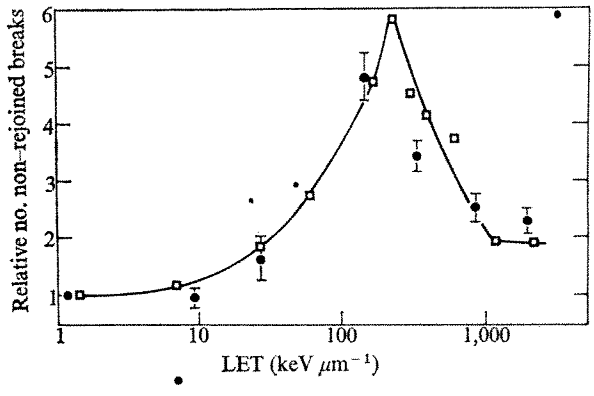

Fig. 2 ●, Relative efficiencies for non-rejoining break induction at various LETs: values obtained by combining results in Fig. 1*a* and *b* and normalising to the value obtained for X rays. ☐, Relative efficiencies for single-hit cell killing: these values were derived from data of Todd[18,19] for T-1 human kidney cells.

possible for intrastrand DNA breaks within a certain critical distance of each other to be repaired, or a break near some other lesion, such as a protein-DNA cross-link, might be inaccessible to repair enzymes. As is the case with double-strand breaks, high-LET radiations should induce these hypothetically non-repairable double lesions more efficiently than low-LET radiations.

Cell killing by ionising radiation can be characterised by two independent mechanisms having lethal, single-hit and sublethal, multi-hit attributes. Our results offer a molecular explanation of the lethal, single-hit component, relating it to non-rejoining DNA strand breaks. The identity of other lesions responsible for the sublethal component remains undefined, although it has been postulated that these lesions are rejoinable DNA single-strand breaks[17,29].

We thank Drs Robert B. Painter and Cameron J. Koch for helpful discussions, and Dr Graeme P. Welch for design and operation of accelerator-related equipment. This work was supported by the US ERDA.

Electrical demonstration of rapid light-induced conformational changes in bacteriorhodopsin

BACTERIORHODOPSIN (a purple pigment) is a light-driven proton pump[1,2], found in patches of the cell membrane of *Halobacterium halobium*[3,4], and is chemically similar to the visual pigment rhodopsin of animal eyes[4]. In both molecules the chromophore retinal is linked as a protonated Schiff base to a lysine residue of the apoprotein opsin[1,5,6]. Light induces bacteriorhodopsin to move protons from the inside to the outside of the cell. The resulting electrochemical proton gradient across the membrane is finally used to synthesise ATP. We report here the application of a new technique for the direct measurement of small capacitative charge displacements in oriented molecules. Our photoelectric measurements using asymmetrically aligned bacteriorhodopsin demonstrate that this protein undergoes reversible conformational changes after absorption of light.

Flash spectroscopy shows that bacteriorhodopsin undergoes a cycle through at least five different spectroscopically defined intermediates[7]. About 8 ms after bleaching the pigment returns to its original form. This cycling time is in good agreement with the maximal 'proton pumping' rate at saturating light intensities. Measurements show that a single protein molecule can transport up to 100–200 protons per second[8].

It is conceivable that the excited bacteriorhodopsin molecule, in addition, passes through a conformational transition sequence to accomplish the vectorial proton transport[9]. Such conformational changes are expected to generate charge displacements within the protein. To measure this effect electrically, two basic requirements have to be fulfilled. First, the molecules must be oriented in parallel but asymmetrically and second, they must be synchronisable, that is, they have to start with the change at a common zero time.

The most favourable system for fulfilling these conditions is found in photoreceptor cells of animals. Here, rhodopsin molecules are strongly oriented in lamellar cell structures, and synchronisation is achieved by means of short flashes. Fast capacitative photopotentials from a wide variety of photoreceptor cells have been measured, and have come to be known as 'early receptor potentials' (ERPs) (ref. 10). The signals are generally attributed to conformational changes within the rhodopsin molecule as it passes through its bleaching sequence[11].

We have succeeded in developing a model system in which rhodopsin from bovine retinal rod outer segments is reoriented on to one side of a thin Teflon film separating two aqueous phases[12]. Flashes to the layer evoke fast photovoltages and photocurrents (depending on the measuring device). Since the layer, having virtually infinite resistance when arranged between two aqueous phases, can be considered as a capacitor, the observed photoelectric response is due to pure capacitative charge displacements. Such model layers offer, for instance, the advantage of allowing the measurement of true transition time courses unaffected by cell membrane time constants. We have now applied this approach to bacteriorhodopsin layers.

Surface-active material from the aqueous suspension of purple membrane fragments was obtained by agitation until foam formed. About 100 µl of the foam was transferred to one side of a two-compartment Teflon cell containing a 4 M NaCl subphase. Thereafter it was overlaid with hexane. The surface film in the water–hexane interface was apposed to a vertically mounted Teflon septum (6 µm thick) by slowly increasing the water level. The chamber on the other side of the septum contained only electrolyte. Thus, the model system consists of the spatial sequence: electrolyte–bacteriorhodopsin–Teflon–electrolyte. The Teflon septum between the two half-cells acts as an electrical insulator and couples the compartments only capacitatively. The two identical electrolyte solutions were connected by silver–silver chloride electrodes to a high resistance input electrometer ($10^{14}\Omega$; 20 pF) (ref. 12).

The voltage responses of this layer when illuminated with bright white flashes are illustrated in Fig. 1. The individual oscilloscope pictures originate from sequential flashes to the same layer. They differ in the time axis to delineate the full time course of the signal.

Analysing the photopotential time course for exponentials leads to, at least, three clearly distinguishable transitions: the signal increases with a fast time constant $\tau_1 \sim 1$ ms and a slower one, $\tau_2 \sim 15$ ms. The main decay back to the initial potential occurs with $\tau_3 \sim 1$ s. Correlating these time constants to those of the spectral intermediates is not feasible at the present time and with the present technique. In spite of this, the close agreement of τ_2 with the 412 nm→570 nm transition ($\tau \sim 12$ ms) is striking. Also, millisecond spectral transitions have been observed which could coincide with τ_1 (ref. 9).

Since bacteriorhodopsin undergoes a cyclic photoreaction, the photovoltage would be expected to be reversible; and indeed it is. The bleaching cycle in the purple membrane is completed in approximately 10 ms, whereas in the model layer about a second is required. This discrepancy of two orders of magnitude is tentatively attributed to the different arrangement of the protein in the two systems: *in situ*, a lipid bilayer matrix, two sides of the protein contact aqueous media[13]; whereas *in vitro*, the protein is in contact with water only on one side—the more hydrophilic one. If a water-soluble reactant (presumably protons) is required for regeneration at the side where the bacteriorhodopsin molecule touches the Teflon surface, then the hindered accessibility would account for the inhibition of regeneration.

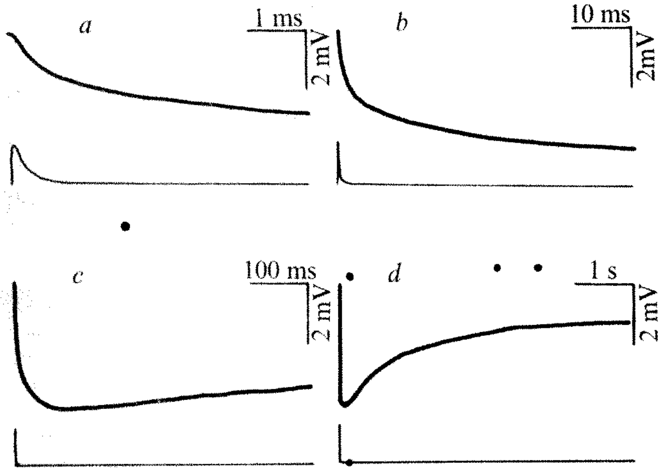

Fig. 1 Examples of the photovoltage of a bacteriorhodopsin layer, 6 mm in diameter, in response to white light flashes. Purple membrane fragments, prepared according to Oesterhelt and Stoeckenius[14], were suspended in 3.0 ml basal salt sodium 4.35 M NaCl, 0.275 M KCl, 0.08 M $MgSO_4$, 9 mM Na citrate, *p*H 7.0) at a protein concentration of 0.5 mg ml^{-1}. The aqueous subphase contained 4 M NaCl and 10 mM imidazole adjusted to *p*H 7.1 with HCl. The experiments were carried out at room temperature (22 ± 1 °C). Each oscilloscope trace includes the time course of the flash at the bottom. Subsequent flashes were separated by more than 1 min. The following amplifier time constants were chosen: *a*, 1 Hz–10 kHz; *b*, 0.1 Hz–3 kHz; *c*, d.c.–1 kHz; *d*, d.c.–0.1 kHz.

The polarity of the voltage is negative on that side where the layer is formed. This is the expected polarity for protons moving from the aqueous phase to the bacteriorhodopsin layer. If this were so, then a strong increase in photovoltage amplitude should result from reducing the ionic strength. Furthermore, the time constants recorded above should depend on proton concentration. Changing the electrolyte (while the layer remains apposed to the Teflon), from 4 M NaCl to 4 mM NaCl and then back to 4 M NaCl, however, did not alter the photovoltage amplitude nor the time constants τ_1, τ_2, τ_3, at any stage of the manipulations. Apart from stressing the stability of the bacteriorhodopsin layer this experiment rules out an origin of the photovoltage from a diffused ion double layer at the aqueous interface. More likely, the effect is based on charge or dipole reorientations in the bacteriorhodopsin molecule itself.

Changes of *p*H in the subphase at constant ionic strength did not significantly affect the time constants, τ_1 or τ_2 (range, *p*H 4–9). One effect of increased proton concentration is a faster decay of the photovoltage transient to zero. For instance, at *p*H 7, $\tau_3 = 2$ s and at *p*H 4, $\tau_3 = 0.5$ s. This gives further support to the above mentioned explanation for the slow regeneration rate: the increased proton concentration at lower *p*H compensates for the hydrophobic location of the hypothetical regeneration site.

At low *p*H the photovoltage amplitude increases slightly. A layer, which displays at *p*H 9 a maximal amplitude of 3 mV displays at *p*H 4 about 7 mV. At *p*H 3 the shape of the photovoltage response changes dramatically; the negative phase is reduced in its amplitude and a very fast positive transient of 3 mV appears. The whole signal has a duration of 200 ms. These experiments indicate a proton contribution to the generating mechanism; since this is already localised in the protein (independent of ionic strength), the photovoltage or a part of it may directly reflect a proton movement in the protein molecule.

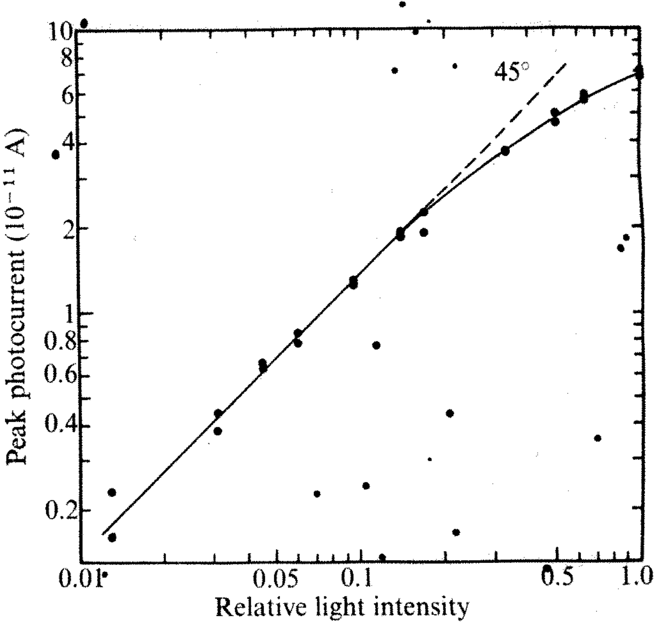

Fig. 2 Peak photocurrent as a function of the flash intensity. The increase in amplifier current time constant was limited to 1 ms. Neutral density filters were used to reduce the flash intensity. ● Data were obtained from one layer.

Since the bleaching of bacteriorhodopsin is reversible, it is possible to apply many flashes to the same layer, retrieving reproducible responses: one layer can be exposed a hundred times to a saturating flash without significant alterations of the photovoltage.

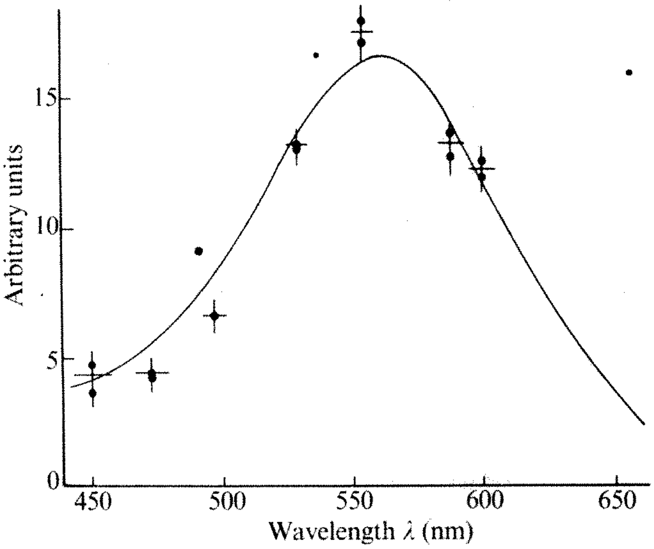

Fig. 3 Action spectrum of a bacteriorhodopsin layer. Solid line represents absorption spectrum of aqueous suspensions of bacteriorhodopsin. Each data point derives from the peak photocurrent at the given wavelength, normalised to the number of photons within the flash. Horizontal bars indicate the interference filter bandwidth at 50% transmission, and vertical bars represent the estimated experimental error.

The photoelectric effect can also be detected as a photocurrent if the electrodes are connected to an ammeter. In this case a photocurrent transient, which is exactly the first time derivative of the photovoltage, is measured. Therefore, the peak in the current transient reflects the steepest slope of the voltage. Since reducing the flash light intensity decreases the photovoltage amplitude, without affecting the shape, a dependence on light intensity could also be measured as the peak photocurrent amplitude. This method provides a better signal-to-noise ratio and is therefore used in the experiment illustrated in Fig. 2. For dim flashes the peak photocurrent is directly proportional to the light intensity. Brighter flashes lead to sublinear responses, indicating a saturation behaviour.

To further establish that the photoresponses result from bacteriorhodopsin bleaching, an action spectrum was obtained (Fig. 3), using the 'current' mode described above. The individual peak photocurrents lie without exception within the linear portion of the curve shown in Fig. 2. The absorption spectrum of the bacteriorhodopsin suspension used in the experiments (solid line) is fitted with its amplitude to the date points. The good agreement of both identifies bacteriorhodopsin as the molecular species responsible for the photoelectric effects.

We thank Dr N. Nelson (Department of Biology, Technion, Haifa, Israel) for bacteriorhodopsin. This work was supported by the Deutsche Forschungsgemeinschaft and CONACYT, Mexico.

Catalytic effect of nitrosophenols on *N*-nitrosamine formation

THE effect of phenolic compounds on the rate of nitrosation of secondary amines is not a simple one. Tannins inhibit nitrosamine formation[1], but in suitable conditions gallic acid catalyses the nitrosation of diethylamine, the rate being dependent on *p*H and gallic acid concentration[2]. Some phenolic constituents of smoked foods[3] inhibit nitrosation of morpholine at *p*H 3.0. Phenolic compounds react with nitrite at a much faster rate than do secondary amines[4], but chlorogenic acid and 4-methylcatechol catalyse[5] the nitrosation of piperidine at gastric *p*H. We report here that nitrosophenols can catalyse *N*-nitrosamine formation.

Nitrosophenols are formed by the nitrosation of phenols and their presence in cured smoked meats has been demonstrated[6]. The reaction we studied was that of 0.15 M sodium nitrite with 0.15 M pyrrolidine in citrate buffer, *p*H 5.0, at 37 °C. Perchloric acid was used to bring the pyrrolidine solution to *p*H 5.0 before mixing. The effect of *p*-nitroso-*o*-cresol on this reaction was studied at 0.25, 0.50, 0.75 and 1.0 mM concentration using the method of initial rates. Aliquots were taken from the reaction mixtures at 5-min intervals for 20 min. Each aliquot was quenched with a solution of ammonium sulphamate in 2 N H_2SO_4 to remove unreacted nitrite, and the nitrosopyrrolidine (NPy) was extracted into dichloromethane and determined by gas–liquid chromatography. Each reaction was repeated in triplicate. For each reaction a plot of NPy concentration against time gave a straight line, the slope of which gave the rate of formation of NPy. Figure 1 shows a plot of the rate of NPy formation against nitrosocresol concentration. Figure 2 shows a plot of the logs of these two properties. That the points in Figs 1 and 2 do not fall exactly on straight lines may be due partially to the poor solubility of *p*-nitroso-*o*-cresol in the citrate buffer solution used. The slope of the line in Fig. 2 calculated by the method of least mean squares is 0.81, and this represents the order of the reaction with respect to *p*-nitroso-*o*-cresol. The two other nitrosophenols we have tested, *p*-nitrosothymol and *l*-nitroso-2-naphthol, also catalysed NPy formation at *p*H 5.0. No reaction takes place between *p*-nitroso-*o*-cresol and pyrrolidine at *p*H 5.0 in the absence of nitrite. The formation of NPy therefore does not occur simply by a trans-nitrosation process from nitrosocresol to pyrrolidine. We found that *N*-nitrosation does not occur in the organic phase during work-up by reduced nitrite species. Such nitrosamine formation requires the presence in the organic phase of nitrosating species and pyrrolidine. The acidic quenching procedure employed in these experiments, besides removing unreacted nitrite, will protonate unreacted amine. The protonated amine should remain in the aqueous layer during dichloromethane extraction. To check that this was so we prepared a 0.15 M solution

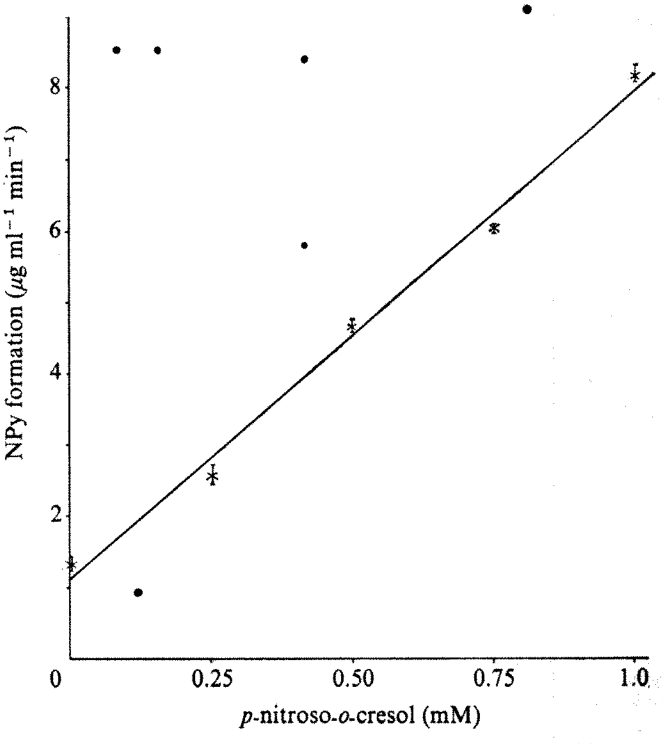

Fig. 1 Dependence of the rate of formation of *N*-nitrosopyrrolidine on the concentration of *p*-nitroso-*o*-cresol.

of pyrrolidine in pH 5.0 buffer, and put an aliquot through our quenching and extraction procedure. The organic extract was analysed for pyrrolidine in free and protonated forms. Free pyrrolidine was not detected, subject to a detection limit of 0.5 μg ml^{-1}. The level of total pyrrolidine (free plus protonated) detected in the extract was >1.0 μg ml^{-1}. The amount of NPy that could be formed from this is insignificant compared to the levels being detected in the reactions. In a reaction mixture containing sodium nitrite (0.15 M), pyrrolidine (0.15 M) and p-cresol (0.075 M) in citrate buffer at pH 5.0 the concentration of NPy formed after 1 h was two and half times greater than that formed in a control reaction from which p-cresol was absent. It therefore seems that at suitable concentrations the presence of phenols can lead to an enhancement of the rate of nitrosamine formation.

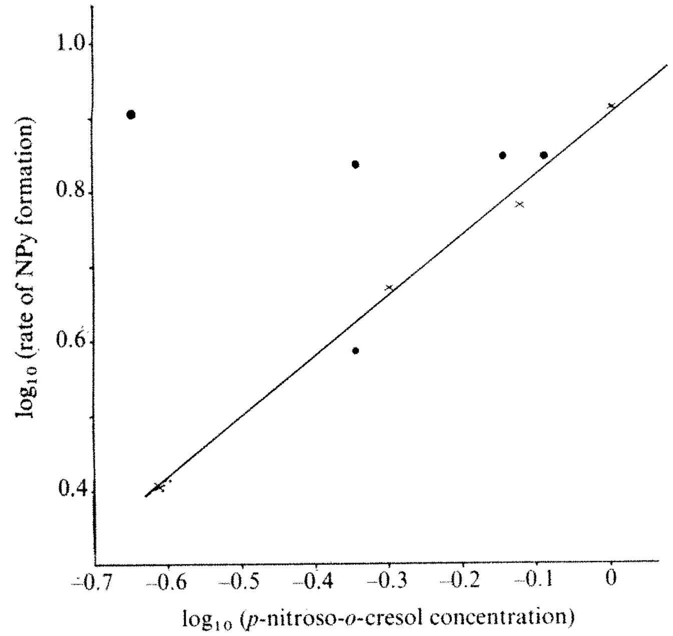

Fig. 2 Logarithms of the rates of formation of N-nitrosopyrrolidine plotted against the logarithms of the concentrations of p-nitroso-o-cresol.

Other kinetic data[4] suggest that in a system containing nitrite, a phenol and a secondary amine, the phenol should be nitrosated at a faster rate than the secondary amine. The initial product of phenol nitrosation is the nitrosophenol, a relatively unstable species, which can be oxidised by atmospheric oxygen to the stable nitrophenol. In this system there are therefore two opposing effects on the rate of nitrosamine formation. The rate will be retarded by the phenol, but catalysed by the unstable nitrosophenol formed during the reaction by nitrosation of the phenol. The overall effect is likely to depend upon whether the steady-state concentration of nitrosophenol (as determined by the relative rates of its formation and its destruction by oxidation to nitrophenol) is sufficiently large to overcome the inhibitory effect of the phenol. In turn this will depend upon the relative degrees of retardation and catalysis of nitrosamine formation exerted by the phenol and the nitrosophenol respectively.

These observations elucidate the basis for some of the conflicting reports of the effects of phenolic compounds on the rate of formation of nitrosoamines, but the implications in terms of the formation of nitrosamines in cured meats and *in vivo* are not clear. The effects of phenols at up to 300 mg kg^{-1}, which may be found in smoked meats (Knowles, M. E., unpublished) and of the 42–300 mg of phenolic material excreted daily into the stomach via gastric juice[7] are likely to be much more complex. The complicating effects of other soluble and insoluble components and of adsorption effects in heterogeneous systems are not susceptible to quantitative prediction; our studies of the catalytic effect of phenols which we have noted as being exerted through the formation of nitrosophenols are being extended to examine these additional factors.

We thank Mr Alan Young and Mr Colin Crews for technical assistance.

Carter's nuclear moves

THIS week, President Carter is set to unveil his much heralded and extensively leaked energy policy. He has been warning for weeks that its emphasis on conservation and its moves to increase energy prices will be politically unpopular, a fact vividly confirmed last weekend when, even before the policy was officially released, it came under attack in three separate television interviews given by Senator William Proxmire, the consumer advocate Ralph Nader and the Republican National Committee Chairman William Brock —people whose political philosophies span a wide spectrum.

Clearly, it will be a severe test of the fledgling Administration's political skills to push the energy proposals through a Congress which is all too aware that soaring energy prices may swiftly translate into plunging electoral votes. Nevertheless, Carter has suggested that he is willing to try, even at the expense of a few percentage points in his popularity rating.

While Carter's domestic energy proposals are running into heavy fire at home, his efforts to curb nuclear proliferation have been attracting equally fierce and often self-interested attacks abroad. The non-proliferation proposals, announced in advance of the other energy proposals, have been criticised unofficially by some West European governments who grumble that the United States may be trying to keep them out of a lucrative business in which they have a technological lead. And it has been attacked in some developing nations as an attempt by the United States to maintain the gap between rich and poor.

First, it is important to understand just what Carter did and did not say. There was nothing very surprising in his announcement, for Carter had signalled his punch months ago during campaign speeches and in some previous Presidential pronouncements. It was not a comprehensive, detailed discussion of major proposals. Instead, Carter simply stated several policy options which his Administration intends to pursue. They are:

- The United States will defer indefinitely the commercial reprocessing of fuel from power reactors and the recycling of plutonium. This means that no federal aid will be supplied to start up a reprocessing plant built by private industry in South Carolina, and that plant may well be mothballed before it even starts operating.
- The liquid metal fast breeder programme, which has previously enjoyed pride of place as the highest priority energy research and development programme in the United States, will be scaled down and restructured to give more emphasis to research and less to development of demonstration reactors. The programme will not be scrapped, however.
- More funds will be put into research on alternative nuclear fuel cycles, such as the thorium cycle, which may pose less risk of proliferation.
- The United States will increase its production capacity for enriched uranium in order to provide assurances to countries which agree not to develop nuclear weapons of adequate fuel supplies well into the future, the objective being to try to dissuade other nations from building their own enrichment and reprocessing plants to ensure their fuel supplies.
- The United States will continue to embargo export of equipment or technology that would permit enrichment or reprocessing by non-nuclear weapons states.
- Discussions with both nuclear exporters and importers will continue, and the United States is willing to explore various arrangements aimed at developing international fuel cycle facilities and access to spent fuel storage facilities for countries sharing non-proliferation objectives.

The only new policies announced are the renunciation of domestic reprocessing by the United States and the sharp reduction in efforts on the breeder reactor programme, both of which are important precursors to international non-proliferation talks. The proposal to defer domestic reprocessing was strongly urged recently by a committee established by the Ford Foundation, whose report seems to have provided the basis of Carter's policy. The reasoning, which is persuasive, is that if the United States pursues domestic reprocessing while trying to dissuade others from doing so, it would be accused of setting a double standard and its credibility would be destroyed. Moreover, since the United States has relatively large coal and uranium resources, the incentive to reprocess is small, at best.

Carter quickly acknowledged that other industrial countries might see their own domestic programmes in a different light, since their future energy supplies might not be so stable as those of the United States. Nevertheless, the onus is now on those countries which intend to reprocess to discuss publicly the reasons which compel them to push ahead at the possible expense of some lessening of control over proliferation.

The next opportunity to discuss these matters in an international forum will be at the secret talks between nuclear suppliers which are due to resume in London in the next few weeks. Carter's statement, released a month before the talks are scheduled to resume, has set the stage for the talks and it has provided plenty of opportunity for a more thoughtful response by European governments than the mostly self-serving reactions which have been voiced unofficially so far. ☐

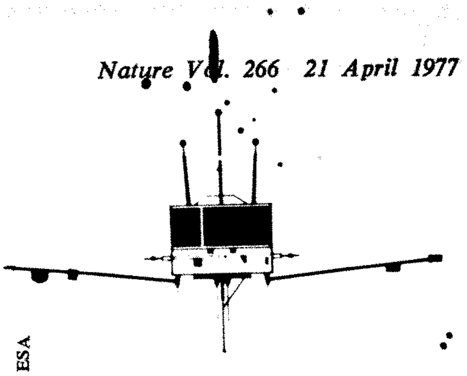
Geos

Europe's satellite for science

Geos, the ESA's purely scientific satellite, is launched this week. **Stuart Sharrock**, now in Florida, reports



ESA

THE EARTH lies inside a leaky magnetic bottle which is formed by magnetic field lines linked to the earth. Called the magnetosphere, it stops the blast of particles from the sun penetrating to the ground and prevents the escape of ionised particles from the upper atmosphere. Occasionally leaks occur, producing aurora and terrestrial magnetic storms that play havoc with radio communication and electrical power distribution. But more significant is the role the magnetosphere plays in controlling the earth's climate. Solar–climate correlations are well established and although it is clear that the magnetosphere mediates between the solar wind and the atmosphere, the exact mechanisms by which it does so are not understood in spite of the several hundred satellite missions already flown.

Study of the magnetosphere is clearly important, for it should lead to an understanding of the environment which will bring economic benefits; but there are other reasons for investigating its properties. Ninety nine per cent. of all matter in the universe is in a plasma state interacting with a magnetic field and the process by which magnetic field energy is transferred to ionised particles is of fundamental significance. This process occurs in the magnetosphere, which is therefore a unique laboratory—a private universe in our own backyard—in which we can study small-scale versions of the fundamental mechanisms that govern the behaviour of matter in the universe. Potential prizes from probing the magnetosphere range from more accurate weather predictions to a better knowledge of the nature of pulsars; from an understanding of aurora to improved prospects for controlled nuclear fusion. The basic structure and processes of the magnetosphere have now been identified and an attack has been launched on the detailed mechanisms and the dynamics of the system as a whole. It is known as the International Magnetospheric Study (IMS) and will run from 1976–79.

Two major satellite missions are at the heart of the IMS: the world's first purely scientific geostationary satellite, ESA's Geos, and a combined NASA/ESA venture comprising three satellites code-named ISEE (International Sun Earth Explorer). Geos is scheduled to be launched on 20 April and ISEE on 14 October; as the centrepiece of the IMS, Geos has been designated the reference spacecraft for the study and will coordinate with ground-based, balloon, aircraft and rocket programmes.

The magnetosphere

A solar wind of protons and electrons blows continuously through the solar system at some 400 km s^{-1} and, according to Alfven's 'frozen-in' theorem, drags with it the Sun's magnetic field. The earth's dipolar magnetic field and the ionospheric plasma are similarly frozen together. These two magnetic fields cannot mix and so the earth's field lies in a closed cavity in the plasma stream from the Sun and presents a tiny obstacle to the blast of the solar wind. This magnetic bubble is the magnetosphere; it is deformed from a dipolar configuration by the solar wind and the size of the magnetospheric cavity changes in response to the strength of the wind. At typically 10 earth radii the hot plasma from the Sun is deflected and streams around the earth's protecting magnetic bottle; under certain conditions however the bottle becomes open to the solar wind —with drastic consequences. Within the magnetosphere there are numerous plasma regions which respond to changes in the solar wind and which interact with the ionosphere and the atmosphere.

Observations with a single satellite can never distinguish unambiguously between spatial and temporal variations; two satellites orbiting together with a known separation are needed and this is one of the aims of the ISEE mission. Geos will sample the different regions of the magnetosphere, measure minute variations in all the particle and wave parameters without interference from the satellite itself, monitor conditions continuously over many months, and yet be capable of responding to changing situations in minutes, and explore the coupling between the magnetosphere and the ionosphere by enabling correlated satellite and ground-based measurements. These requirements specify a satellite with an orbit, construction and performance an order of magnitude more complex and sophisticated than any previous ESA satellite and with a control and ground support system more ambitious than has so far been attempted by NASA with unmanned missions.

The Geos satellite

Built by a consortium of European industrial contractors headed by the British Aircraft Corporation, Bristol, England, Geos will be placed into a geostationary orbit 36,000 km above the equator. The orbit covers a region of the magnetosphere where many of the dynamic processes responsible for magnetic and ionospheric disturbances are believed to develop; the satellite will be positioned at longitudes where the magnetic field lines are conjugated to both auroral zones (that is, particles passing along the field lines through the satellite will arrive at the aurora), allowing correlated measurements to be made from ground stations and rocket-borne instruments.

As the spatial variations seen by Geos will be small, the time and space ambiguities will be minimal and short-lived transient phenomena can be studied. Sampling of different regions of the magnetosphere will be automatic as Geos alternates between the day-side and the night-side, but the boundaries of the different magnetospheric regions are not fixed in space and will at times move across the geostationary orbit under the influence of the solar wind; phenomena associated with such boundary crossings are of particular interest.

Once in orbit, Geos will be permanently in view of a purpose-built tracking and data recovery ground station near Darmstadt in West Germany (also to be used for Meteosat). The continuous link between the satellite and the ground allows for high data rates, which are essential for some experiments, and means that real time modification of experiments becomes possible. The capability of closed loop control of instrument modes is crucial and was laid down as a ground rule for the mission in the early planning stages.

The problem with many satellite experiments is that effects caused by the spacecraft itself can often mask or destroy the phenomena of interest. Spacecraft charging is well known—

potentials of up to 10 kV have been reported from the ATS satellites during eclipses—and can have disastrous effects on experiments to measure low energy particle fluxes. To minimise this problem the whole of the outer skin of Geos has been made conducting, thus ensuring that the surface is an equipotential. There is a complex system of eight booms which deploy in orbit to take the sensitive detectors up to 20 m away from the disturbing influence of the satellite body; this is the most complex boom system attempted for any European satellite. The experiments mounted on Geos involve extremely sensitive measurements (for example the detection of magnetic variations of a thousand millionth of the strength of the earth's magnetic field) and this has meant an extensive programme to minimise electromagnetic interference caused by equipment on the spacecraft.

The experiments

The achievement of providing a magnetospheric laboratory free from interference, accessible in real time and controllable from the ground is matched by the scope of the experiments comprising the payload. To understand the magnetosphere's structure and the wave–particle interactions that occur, it is essential to make sensitive measurements of all relevant parameters simultaneously. For the first time this is being done and data on every quantity of interest are being collected: four experiments will measure particle fluxes and their variation with energy and direction, covering a range from thermal energies to hundreds of keV, and three experiments will measure electromagnetic waves over a frequency range 0–77 kHz for electric fields and 0–20 kHz for magnetic fields. DC electric and magnetic fields will be monitored with extreme sensitivity. The most important measurements will be duplicated by independent experiments.

A mission this complex cannot hope to satisfy all the requirements of a number of coordinated campaigns; many of the needs are mutually exclusive and inevitably compromises must be made. The coordination of activities is crucial to the success of the mission and has been an important factor in its planning. Areas in which the standard configuration is not ideal can hopefully be covered by special arrangements; the project has the inherent flexibility to allow this.

As an example, a polar expedition to a ground station in the Arctic could be unhappy about the orientation of Geos. The expedition will want to correlate its measurements with particle fluxes coming from the south at the position of Geos but this is only possible during the northern winter. The directional coverage for particles is not isotropic and the orientation of Geos is governed by the requirement that the radial booms do not shadow the solar cells. Inversion of the satellite —a delicate operation—would have to be arranged but it would interfere with the wave experiments and expeditions to the Antarctic would not be too happy. Other ground stations would no doubt have conflicting requirements. Rocket campaigns, for example, are costly and can only be conducted at certain times, and these are sure to be the times when interesting transient effects are manifesting themselves and necessitating an immediate change in plan. In any case there is only a limited supply of fuel so manoeuvres are rationed. The coordinating committee will have a tough time but the number of demands made on the mission is a measure of its flexibility and importance; the number of satisfied customers is likely to be very high. Crucial to this flexibility is the provision of extensive computing facilities at the ground station where the data are collected.

Coping with data

Most of the time nothing exciting will happen (the magnetosphere can remain stable for long periods) and it is unwise to accumulate vast quantities of data throughout the mission. Filling a magnetic tape every 45 minutes, Geos would generate 26,000 tapes over a two year period of which only about 10% would be worth keeping. The solution is to recycle the magnetic tapes every three months; there is an extensive data distribution system (it includes daily summaries of all Geos data) to enable a communal decision on which data are to be retained. Not only does Geos have the ability to respond quickly to changes in the magnetospheric system, it also imposes a requirement on the experimenters to respond to their data within a reasonable time period—a valuable constraint that could be more widely adopted.

Originally planned for August 1976, the launch of Geos has been delayed until April 1977 mainly because of late delivery of components. The satellite will be launched by a NASA Delta launch vehicle from the Kennedy Space Center in Florida. The original flight plan has been continually modified to take account of the magnetic conjugacies between a given longitudinal position of the satellite and the positions of available ground stations and rocket campaigns. The current plan is to station it initially at a longitude of 0°, where a double magnetic conjugacy exists between Iceland in the northern hemisphere and the Syowa base in the southern hemisphere. In about August this year Geos will be drifted eastwards to arrive at about 35° E by October 1977; this is a position ideally suited for correlated measurements with the extensive array of ground-based stations and rocket ranges in Northern Scandinavia. In mid-1978 the satellite could be thrust back to the 0° position again, further movements being a function of the status of polar expeditions, rocket campaigns, ground stations, the amount of fuel remaining, the consensus of opinion and the tempers of the Coordinating Committee.

After lift-off it will take about a month to get Geos into its correct orbit with the extensive boom system correctly deployed, another month to check out the experimental payload; by then hopefully it will be fully operational and the IMS can start in earnest. The taxpayers of Europe have made a wise investment in Geos—if NASA gets it up there. ☐

An artist's impression of Geos in the magnetosphere

A partial triumph

Vera Rich assesses the Moscow Seminar, which celebrates its fifth anniversary this month

THE illicit Moscow 'Sunday Seminar' for refusnik scientists was founded five years ago this month. In a remarkable development after such a lengthy period of harassment of its organisers and participants, the Soviet authorities have now informed Professor Mark Azbel, the current leader of the seminar, that he may hold a special anniversary meeting this week provided it is confined to matters of strictly scientific interest.

The first Sunday seminar for refusnik scientists—that is, Jewish scientists dismissed from their posts and deprived of all official means of pursuing their careers—took place in Moscow on 12 April 1972. The date is significant— 1972 was the year of the 'education tax', by which any Jew wishing to emigrate to Israel was obliged to repay to the government the 'cost' of any higher education he may have received. And since such education is provided *gratis* by the State, the authorities could clearly fix its notional cost at any value they chose.

Scientists wishing to emigrate became liable to long waiting periods between applying for a visa and receiving permission to emigrate. They therefore began to form one of the most significant social groups within the growing class of *otkazniki* (the word which later became transformed in English to 'refusnik')—those not permitted to leave the country, yet deprived of their professional means of livelihood within it.

Moscow meeting

Against this background, a modest group of 17 scientists met in the Moscow flat of Dr Henrikh Sokolnik in April 1972. The venue was chosen because Dr Sokolnik is a chair-bound cripple. Their aim was to read papers of mutual interest and thus to keep up the interplay of ideas without which scientists cannot function professionally. Throughout 1972 the group functioned quietly without attracting the attention either of the Soviet authorities or of Western sympathisers. Even the weekly Bulletin *Jews in the USSR*, founded that year to publicise the plight of refusniks and Jewish prisoners of conscience, made no mention of the seminar, although it carried numerous appeals from scientists to their colleagues abroad, and news items about scientists suffering particular hardship (notably Dr Evgenii Levich, who in that year was sent to a Siberian labour camp).

It was not until 1973 that the first information about the seminar began to reach the outside world. In that summer, when an International Conference on Magnetism was meeting in Moscow, several Western scientists, learning of the exclusion of the refusniks from the conference, made their way to the flat of Professor Aleksandr Voronel, where the seminar was then meeting, and took part in a lively and informative discussion. From this contact the idea arose of holding an International Session of the seminar the following summer.

The International Session was widely announced. In addition to Professor Voronel, two organising secretaries, Dr Norman Chigier of the University of Sheffield and Dr Edward Stern of the University of Washington, Seattle, were appointed. Papers were invited on an international basis, and more than 50 leading scientists, including seven Nobel prize-winners, lent their names, either as patrons or as would-be contributors. The preparations caused considerable disquiet to the Soviet authorities which, in the stress of the situation, made what can be seen in retrospect as a tactical mistake.

Had the seminar been permitted to take place, then coming as it did at the height of the scientific conference season (July) and virtually coinciding with President Nixon's visit to Washington, it might have merited at best a paragraph in the foreign press as a promising sign of a new 'thaw'. Instead, prospective Western visitors were denied entry visas, the proposed venue was put under KGB supervision, the Moscow organisers were arrested and taken to detention centres outside the city, and other would-be participants were kept under virtual house arrest. The 'Seminar-that-never-was' accordingly went into history as a major example of State interference in academic freedom, and the 'Voronel Sunday Seminar' became an important (if unofficial) item on the schedule of scientists visiting Moscow in the course of their professional duties. It is estimated that, to date, some 150–200 foreign visitors have attended the Seminar.

Remarkable survival

The survival of the seminar over five years is, under Soviet conditions, remarkable. Of all those who took part in the first meeting only one is still in Moscow: Corresponding-Academician Veniamin Levich. The others, one by one, and largely due to pressure from their Western colleagues, have received their permission to leave. Professor Voronel himself received an exit visa some six months after the non-occurrence of the International Session, and his role as leader has been inherited by Dr Mark Azbel, with, in recent months, Dr Anatolii Shcharanskii acting as press attaché and contact with the international scientific community.

As the more 'senior' members of the group leave, there are always new refusniks to fill their places, and there seems little likelihood that the need for a seminar will disappear within the foreseeable future. Indeed, the seminar movement has proliferated: by last summer some ten additional seminars had been established dealing with specialised topics, including theoretical physics, computer science, radio-electronics, and biology; and one seminar, in Kiev, after being officially 'closed' by the KGB, began meeting in a public park. Organisers and participants from all groups have experienced constant harassment including police interrogation, confiscation of books and papers, and short-term arrests.

One reason for the Moscow Seminar's survival is undoubtedly the interest shown by many scientists abroad. For them, the existence of a clear-cut ethical issue is involved: the UN Declaration on Human Rights states unequivocally that everyone has the right to leave any country, including his own. But in practice a number of caveats arise as far as scientists are concerned which makes the right difficult to exercise. Access to classified information is one objection; another, which in the case of the Soviet Union gave rise to the notorious 'education tax', is the brain drain with all its attendant questions of how far a student, in accepting a place for higher education, may be deemed to have implicitly entered into a contractual obligation to work in the country which has financed him.

Scientists remain shocked, however, at the idea of their colleagues being prevented from functioning as scientists. The holding of seminars and discussions, access to new publications and correspondence and meetings with foreign colleagues, all constitute a major part of the scientist's basic activity. Even if the Soviet authorities see fit to dismiss from their professional posts scientists so 'disloyal' as to wish to emigrate, and to restrain that emigration in the interests of the State, it seems illogical then to prevent them exercising, even unofficially, that profession which makes them a State asset. The right of the refusniks to hold seminars must appear unequivocal, even to those of their foreign colleagues who are disinclined to enter into long arguments against the Soviet government's pragmatic case for denying exit visas.

Contribution not great

But what, scientifically, is the value of these seminars? From the point of view of the progress of world science, it must be admitted that the Soviet contribution is not great. A handful of papers by refusniks has been accepted by foreign journals, but it is significant that these are by the more mature members of the group—notably Veniamin Fain, Mark Azbel and Viktor and Irina Brailovskii. The papers are, presumably, the working-up of ideas which the authors had no time to develop during their active careers, and for young scientists, who have not yet developed such a back-log of topics, the prospect of publication abroad is probably somewhat bleak.

Nevertheless, from the point of view of the scientists themselves, attendance at the seminar is something more than a holding operation. Soviet science, aimed as it is as serving the national economy, can be extremely narrow, so that one hears of first degrees in such topics as light metal engineering for the civil aviation industry. Moreover, theoretically Soviet science must serve socialism, and every working scientist must, officially at least, formally confirm his political commitment.

In the Seminar all this is changed. Thrown out of their jobs, the refusniks found a new freedom in their release from this tacit agreement to serve political ends. "We stopped mourning for our scientific interests, since, in truth, we had attained the ideal of scientific detachment", Voronel explains in his preface to the 'Proceedings' of the Seminar-that-never-was. At the very first meeting, Levich joked that "This reminds me of my youth. Back in a group of Jews again, and once again they talk nothing but science".

Over the years, this first flush of euphoria has somewhat faded, but the broadening of the participants' interests has not. Asked last week to comment on the achievements of the Seminar during its five years' existence, Professor Voronel remarked:

> "The main difficulty of the seminar has been to combine the different interests of its participants, but it can also be an advantage because they become aware of different fields. This may be of great value to contemporary science, to have such an interdisciplinary forum."

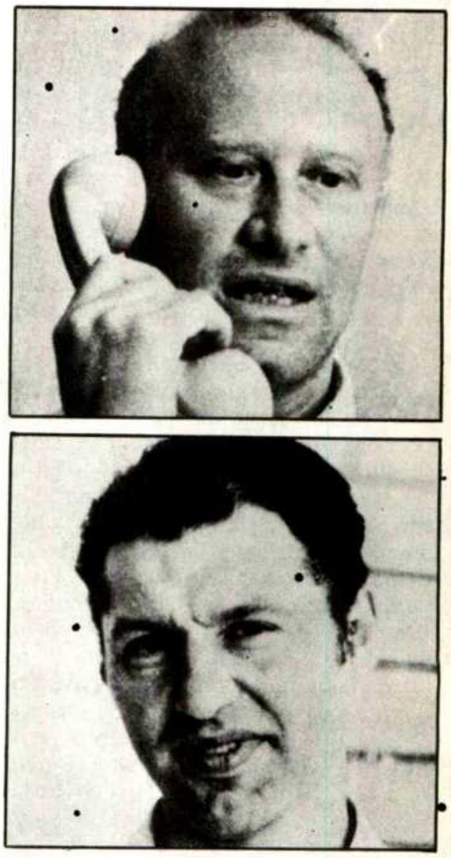
He cited the case of Shepelev, who from a discussion of general principles of phase transitions developed a new approach to his own subject—the strength of rubber and polymers. He also spoke of Roginskii, originally a nuclear physicist, who during the course of the seminars became interested in solid state physics and, on receiving his visa, was able to take up a post at the Hebrew University, Jerusalem, working in this new field.

This broadening of intellectual interests is, of course, considerably restricted by the lack of access to published literature, particularly from abroad. One project in particular, a sociological study for which surveys and questionnaires were distributed under conditions of great difficulty, would have had considerably greater intrinsic value had comparable figures, published during the past few years in the USA, been available for comparison. Foreign scientists have been invaluable as a source of information on the main trends of research abroad, as well as a profound source of moral support.

How much easier?

The fact that the authorities have given permission to hold the one meeting (although, strictly speaking, no such permission is required, since the Soviet constitution guarantees the right of assembly) will not necessarily mean that there will be no interference with the regular Sunday meetings. And, even if these can proceed without harassment, access to published literature will still be restricted to those few members who have retained their right of entry to academic libraries, and to the few hand-written copies of the primary journals available as *samizdat*. Experimental facilities will be lacking, and although the Russian term *nauka* covers the humanities and social sciences as well as the physical sciences, it seems unlikely that the authorities would look with favour on any further attempts to make sociological surveys; the data from the first such survey was confiscated last December.

Any attempts to hold another International Session, as opposed to welcoming visitors on an *ad hoc* basis, would doubtless still be interpreted as a 'foreign provocation', as it was in 1974. Furthermore, Anatolii Shcharanskii, the Seminar 'spokesman', is still in custody, facing the possibility of treason charges being brought against him; and within the past few months several members of the Seminar have been accused in *Izvestiya* of being agents of the CIA. Even if permission were now to be extended to the regular meetings of the Seminar, this would be of little value if it were to be accompanied by harassment of individual participants on grounds other than their membership.



Azbel (top) and Voronel: activists

The granting of the permission is nonetheless of far wider significance than a graduging acquiescence in the holding of a one-off celebration. Just as, in the words of Professor John Ziman, the true value of the Seminar "is not the work they are doing but the fact that they are doing it", so too the significance of this permission is not that the Soviet authorities will permit one special meeting of the Seminar to be held, but the fact that they admit the Seminar exists at all. In 1974 foreign scientists wishing to attend the International Session were refused visas on the grounds that they had not been invited by a *bona fide* organisation. In December 1976, when the Seminar group was to hold a special symposium on Jewish life in the USSR, the leaders were arrested and their right to hold the symposium was emphatically denied. Throughout the past five years, the authorities have done their best to deny the existence of the Seminar, and proceedings against its members and activitists have been brought on other counts, such as 'parasitism' (being without visible means of support) or 'slandering the State'. The granting of permission even for one meeting represents a real achievement, not least for science. ☐

Geophysics stakes its claim

A draft report proposing a massive deep sea research programme is now circulating among US earth scientists. Colin Norman reports from Washington

A PROPOSAL for an ambitious deep sea research programme, costing some $400 million over the next decade, is being put together by a group of earth scientists and will soon be forwarded to the National Science Foundation (NSF) for further study and possible funding. The proposal, based largely on recommendations developed during an international meeting held last month at Woods Hole, Massachusetts, would involve extensive drilling deep into the ocean floor in regions which have not yet been punctured by research probes.

A central feature of the proposal is to convert the infamous *Glomar Explorer,* the vessel used by the Central Intelligence Agency in 1974 to scoop bits of a sunken Soviet submarine from the bottom of the Pacific, into a sophisticated drilling ship. The *Explorer,* which is now in mothballs near San Francisco awaiting a user, would be capable of drilling at depths and in regions which are beyond the reach of present drilling vessels.

Though it is far from certain that the proposal will be funded, at least in its present form, it is sure to attract considerable attention as it wends its way through the federal bureaucracy. And the attention will not be confined to the United States, for NSF is expected to seek international participation in the venture if it decides to apply to Congress for funds.

A draft report outlining the proposal is now being circulated among a number of earth scientists, and a copy has been made available to *Nature.* The proposal would involve a major expansion and re-direction of the Deep Sea Drilling Project (DSDP), a programme begun in 1968 which has resulted in the drilling of more than four hundred holes in the ocean floor in many parts of the world. DSDP now runs an international effort called IPOD1—the International Phase of Ocean Drilling—which is supported by six different countries (the United States, which provides the bulk of the funds, France, Germany, Japan, the USSR and the UK). It has helped to revolutionise thinking about the history of the earth, but after several extensions it is due to expire in September 1979.

The new proposal is thus an attempt to map out a research effort to carry on where IPOD1 is expected to leave off. Drafted by an international committee headed by Manik Talwani of the Lamont-Doherty Geological Observatory, the proposal is the result of an elaborate planning effort involving scores of earth scientists. The committee was established last August by the executive council of JOIDES (Joint Oceanographic Institutes for Deep Earth Sampling)—a collection of research institutes which are taking part in the DSDP—and it was given a broad mandate to plan a research effort stretching over the next decade.

The committee's proposals are based on a series of 'white papers' drawn up by groups of scientists and discussed at the Woods Hole meeting last month. Its report has been approved in principle by the JOIDES executive council, and it is now in the final stages of revision before being published.

The DSDP has already provided masses of information confirming and refining the theory of plate tectonics, according to which the continents were once joined together in larger landmasses which were split apart by processes which still push the continents around. Those processes, known as sea floor spreading, involve the continual generation of new oceanic crust along the mid-ocean ridges where molten lava wells up from the mantle, solidifies and is pushed aside by yet newer lava. This constant generation of new crust gradually forces continents apart and is responsible for a variety of geophysical and geological phenomena, such as earthquakes, volcanoes, and large scale uplift of mineral deposits in many regions where oceanic and continental crusts converge.

Though rock samples recovered from many parts of the world by the DSDP drilling vessel, the *Glomar Challenger,* have produced solid evidence in support of the plate tectonic model, a number of intriguing questions remain (see also *Nature,* **259,** 83). They include a satisfactory explanation of why the continents split apart when they did, a better understanding of the active processes taking place along the oceanic–continental margins and an appreciation of the large-scale climatic and oceanographic changes which have accompanied the formation and evolution of the oceans. Many of those questions could only be answered by drilling into the ocean floor in regions which are at present inaccessible to the *Glomar Challenger.*

In particular, some of the most intriguing drill sites lie along the continental margins in regions where there is a risk of encountering oil and gas deposits, or deep in the ocean trenches where very long drill strings would be required, and at high latitudes where rough seas and ice present problems. A ship capable of coping with those conditions would require massive lifting capacity to handle the heavy equipment needed to prevent blowouts of oil and gas and to operate long drill strings. It would also require powerful engines, a thick hull and good station-keeping ability to work at high latitudes. Such a vessel would cost about $100 million to build, according to NSF estimates, a price tag which probably puts it out of reach. That, however, is where *Glomar Explorer* may come in.

Built for the CIA by Global Marine Inc., the same company which owns and operates the *Glomar Challenger,* the *Explorer* has been idle since 1975 when its mission became publicly known. Though it belongs officially to the federal government, a number of attempts to find a user for the vessel have so far drawn a blank. Last year, however, NSF expressed interest and commissioned Global Marine to study the feasibility of converting the ship into a deep sea drilling vessel. The study, which has recently been completed, concludes that it would cost about $52 million to convert the *Explorer* into a sophisticated drilling vessel, equipped with a riser to prevent blowouts if oil and gas are struck. The cost of operating such a vessel would be about $33,000 per day, about twice that of the *Glomar Challenger.* In other words, the *Explorer* could provide a cutprice entry into the more intriguing drill sites, and the Talwani committee envisages it becoming the principal actor in a deep sea research programme in the late 1980s.

The proposed programme would essentially involve continuing use of the *Glomar Challenger* to drill relatively shallow boreholes in accessible sites until October 1984. In the meantime, the *Explorer* would be converted in time to start drilling in 1981. It is anticipated that the programme would run until October 1987, and the total cost, including preliminary surveys and sample analysis but excluding the cost of converting the *Explorer,* would be about $396 million.

The proposed effort would include drilling in the passive margins—the continental margins which originally fitted together—in an effort to understand the processes which led to the original fusion of the super-continent. Another major thrust would be to drill along the active margins where the Earth's crust is being jostled and subsumed into the mantle, in an attempt to understand some of the geophysical processes involved. Other features of the proposal involve extensive drilling into the ocean crust itself in an effort to learn more about the processes by which it was formed, and to study the evolution and environmental changes which have occurred.

The committee cautions that the programme should not be attempted at all unless there is a firm assurance of support for extensive geophysical survey work before drilling takes place, and sufficient funds to analyse and interpret the results. "An investment in a drilling vessel without a commensurate investment in scientific investigations on an appropriate scale could not be supported in good conscience", the report states.

The proposal will be sent officially to NSF in the next few weeks, and responsible programme officials will seek authority from the Director and the National Science Board to look further into the scientific merits of the plan (a task which, as one NSF official wryly observed last week, will be complicated by the fact that virtually everybody capable of offering an independent opinion participated in drafting the proposal). If the programme is deemed meritorious, NSF will eventually seek funding, first from the Office of Management and Budget and later from Congress. At some stage, it is almost certain that the matter will land on the desk of Frank Press, President Carter's science adviser, who is a distinguished geophysicist himself.

For a project of that cost and scope, international participation would be an obvious advantage. At present, non-US participants in the DSDP each contribute $1 million a year in direct costs and a further sum in supporting the work of their own researchers in analysing and interpreting the results. NSF officials note that economic and political difficulties might mitigate against foreign participation.

The British commitment, for instance, is to support IPOD1 until 1978, and a request for a further year's support is expected soon. The British package of support is complex, however, involving sums of money from three separate departments, and any request for financial commitment at this stage for a period of ten years might pose problems.

The first decade of drilling with the *Glomar Challenger* has provided some spectacular results and answered some fundamental problems. But it has also thrown out some intriguing questions which can be answered only with more expensive equipment which will be more costly to operate. The same pattern can be discerned in fields such as particle physics and even molecular biology. It should be no surprise that it is now happening to geophysics. ☐

NETHERLANDS

Dutch go ahead on DNA

Casper Schuuring reports from the Netherlands on moves to control recombinant DNA research there

RECOMBINANT DNA research should be developed in the Netherlands because of its great scientific importance, according to a report from the country's Commission on Genetic Engineering which was handed over to the Ministers of Health and for Science Policy on 3 March and published on 30 March. The research should be carried out with stringent precautions and according to clear regulations contained in legislation which, in the commission's opinion, should be implemented quickly.

The commission, which started work just one year ago, also proposes a special committee with responsibility for surveillance of the research. It would continue the work of the present commission on a legal basis, and have on it representatives of the biomedical sciences, of other related sciences (legal and ethics), of the government and of society at large. The commission, which consists only of experts in the field, also suggests another committee to consider broader ethical and social aspects of the applications of advanced medical and biological research and whether to bring such research within the framework of legislation.

The commission supports the European Science Foundation's recommendation that the rules of the British Williams report be followed, but considers that on a couple of points the report is insufficiently clear. Plans for recombinant DNA research must be reported to the 'surveillance committee', and research cannot go ahead unless a statement that there is no objection to it has been obtained and an 'examination commission' has been established to check that all requirements are fulfilled. That body has the right to do investigations on the spot.

The commission prefers the description of the four levels of physical containment of the Williams report. It says that a laboratory with the highest containment level should not be established in the Netherlands, and that experiments on that level should be done at a 'European' laboratory, but it says there is a great need for facilities with containment one level lower. Regarding levels of biological containment, the commission has opted for the rules contained in the NIH regulations in the USA. For each experiment the requirements for biological containment will be left to the surveillance committee.

The commission also prefers the NIH view that certain experiments should not be carried out at the moment. The Williams report did not exclude any experiments completely. Those prohibited include the cloning of recombinant DNA from pathogenic organisms (class 3, 4 and 5) or from oncogenic viruses; the purposeful cloning of that DNA from organisms coding for the production of toxins (botulinum, diphtheriae); the establishment of a transfer of resistance against (for example) antibiotics to microorganisms missing that natural resistance; and experiments enhancing the virulence of phytopathogenic microorganisms.

On a list of examples of experiments with non-purified DNA of organisms not secreting toxic products and the conditions under which they should be carried out, the commission separates primates from other mammals, which the Williams report did not do. Concerning prokaryotes the commission distinguishes DNA from organisms which exchange genetic information with *E. coli* and those which do not. In the commission's opinion the second category carries a higher potential risk. Finally, experiments which use nucleic acid from animal viruses not pathogenic for man have to be placed in a higher category than the Williams report suggested.

So far nine projects, one of which is already in progress, have been lodged with the commission. One has to be classified as belonging to the category of research which cannot be carried out in the Netherlands; the level of two others has not been determined, while another two are P1-level experiments and two more are P2 (according to NIH regulations). Two others are P1 projects.

The establishments involved so far are the University of Amsterdam (3 projects), the Free University in Amsterdam (1), the University of Leiden (3), the University of Groningen (1) and the University of Nijmegen (1). Other universities and research institutes are preparing to do recombinant DNA research. From industry only Unilever is making preparations.

The foundation 'Biosciences and Society', which gives information on a regular basis on biomedical subjects, remarked on the report in its 31 March bulletin. It says that the commission, "consisting exclusively of prominent Dutch scientists, has hardly occupied itself with the social desirability of the recombinant DNA-research". It goes on: "The report gives no answer to the critics who doubt whether this research is socially necessary. These critics say that some results can also be reached another way." ☐

EUROPE

Wanted: a science policy

Chris Sherwell reports on a European science policy symposium held in Brussels last week

STRAITENED economic circumstances concentrate the minds of policy-makers wonderfully. The problems of those involved in science policy are worse than most, however, for the additional reason that, with science seemingly everywhere, science policy is seemingly nowhere. But with the research base an important pillar of support for the developed countries' economies, the need for science advice in government rightly remains undisputed, and the need to deal with problems with a scientific content is undiminished. So the search goes on.

As part of that search, the European Commission last week sponsored a three-day symposium at a fashionable hotel in Brussels. Ambitiously entitled "Strategies for Europe: Proposals for science and technology policies", it was organised by the private grouping known as the Science Policy Foundation, and attended by some sixty people drawn from research councils, research institutes, universities, industry and the media as well as governments.

It may remain the most important outcome of the meeting that the lines of thinking developed in recent years under the inspiration of the 'Europe + 30' idea are at least being supplemented and that concern has begun to focus on more immediate problems. If so the involvement of the Science Policy Foundation could increase, although notable absentees from the meeting, particularly from Britain's science policy establishment, may mean that any transfer of legitimacy will take time. A former Director General at the Commission, Michael Shanks, suggested in drawing conclusions from the meeting that there ought to be an organisation of science policy federations whose work could be enriched through association without being subordinate to it, and that this possibility ought to be examined, perhaps by the Commission working with the Science Policy Foundation. There was a need, he said, for the Community to have a loose network of experts independent of political allegiances who could together provide advice on common problems for leaders lacking a science education and thus help to bridge the gap between them and the broad community they served.

To this end Directorate General XII, the department of the Commission which with its responsibilities for research, science and education provided the crucial support for last week's symposium, is now engaged in preparing for two events. One is a three-day symposium which it is organising for June on the issues which the phrase "Science and Society" now commonly embraces. It is understood that this has met with resistance from some scientists and policy makers in certain member countries but has been welcomed by others. The Commission's view is guarded, but it appears prepared to see the issues given an airing under its auspices on pain of withdrawal if the experiment is as fruitless as its critics imply.

Preparations for the other event are less well finalised. It stems from the suggestion in February by Guido Brunner, the European Commissioner for both Energy and Research, of a forum or hearings on the issue of nuclear power. What form these might take remains unclear, but they are likely to be held after the proposed symposium on science and society. What is certain is that, in the aftermath of President Carter's recent announcement on nuclear power, the already strengthening worries of the Commission on the issue have been further reinforced. Faced with an increasingly threatened European nuclear programme and continuing troubles over uranium supplies from North America, the fact that Euratom and the IAEA have now agreed terms on safeguards seems to cut little ice, and this is a matter for some despair. The Carter statement confirms the difficulties of the Commission's own position: its first official response last week (the initiative will be "studied closely") was well muted.

If the symposium was anything to go by, on the science policy front it is now apparent that in Europe there is an emerging concern with two problems in particular. One is the effect of producing increasing numbers of highly qualified science graduates for whom the end of an era of university expansion has coincided with a period of inflation and recession to produce the grim spectre of unemployment. The worry is not just about where the professors of future generations will come from, or about the more fundamental matter of the state of science and research; there is also the practical worry, outside the issue of ageing research staffs, of the sheer waste involved, the opportunities foregone.

For those who choose to ignore such central matters of how much a country should devote to basic research—an issue on which researchers are more and more being called upon to defend themselves—the obvious destination for graduates is industry. But industrial innovation is the other problem over which there appears to be emerging concern in Europe: how is manufacturing industry, the so-called engine of growth, to improve its capacity to generate and harness the process and impact of innovation?

One tangible achievement of the symposium may turn out to be that it encouraged the first steps towards some amelioration of these sorts of problems. On the matter of industrial innovation, for example, in which the Commission has for some time shown an interest, for instance through its so-called Brunner - D'Avignon task force, the prospect emerged of co-operation betwen the Commission and the European Industrial Research Management Association (EIRMA), possibly with the additional assistance of the Science Policy Foundation.

Inevitably the Community's main interest, being borne of shared economic interest, is likely to focus more readily on innovation in this fashion. But it does not confine itself to that, and the symposium also confirmed that the European body that has firmly established itself as the one best placed to answer questions about the overall state of basic research throughout the continent is the Strasbourg-based European Science Foundation (ESF), made up of research councils and academies from 45 member countries.

The European Commission has close links with the ESF, and now plainly recognises its authority to speak on matters of basic research. A keynote address from Dr Gunter Schuster, Director General at DGXII, helped the ESF's President, Sir Brian Flowers, to draw a positive response later to his own intimations that the Commission could assist in efforts to establish a fellowship scheme to help build a European social science and to develop the humanities—a goal which reflects the ESF's own desire to concern itself less with the English *science* and more with the broader German *wissenschaft*. As Sir Brian said, the ESF was not concerned with studying policy; by its activity it contributed to it.

For most practising researchers that view will probably provide some real comfort at a time when their need is not so much for science policy studies as for science policy itself. The question remains whether they can represent this interest successfully. ☐

WEST GERMANY

The cost of maintenance

Werner Gries reports from Bonn on West Germany's funding for science

WEST GERMANY spent DM24,200 million on scientific research and development in 1976: DM12,700 million came from the government, DM10,900 million from industry and the remainder from overseas and from independent foundations. As is customary, 55% of the government contribution was raised by the central government, and 45% by the *Länder* which comprise the federal republic. In contrast to other Western nations, military research and development plays a comparatively minor role in West Germany: in 1976 it received DM1,500 million—6% of the total research expenditure. Since 1973 there has been no increase in the resources available for research and development and plans for 1977 show that in real terms, total expenditure on research will decrease. In 1976 2.2% of GNP was spent on scientific research.

Non-nuclear energy research is receiving increasing support from both the government and industry. The government contribution for specific projects connected with non-nuclear energy amounts to DM270 million in 1977. Some DM300 million will be spent on research centres and other projects. Mining and coal technology are the most important areas receiving government subsidy. New techniques of searching for and developing petroleum, natural gas and uranium are also being investigated, as are the possibilities of solar and wind energy. Solar collectors for heating are now so advanced that the government is considering offering special incentives, particularly investment bonuses, to encourage manfacturers to put new techniques on the market. The government is also subsidising research into new methods of saving energy.

On the nuclear front, West Germany is, amongst other things, developing the fast breeder reactor. About 2,300 people are now employed on the development work and in 1977 about DM380 million will be made available to research establishments and industry for further development. The principal project is the 300 MW prototype reactor at Kalkar, which according to the latest estimates will cost DM2,800 million to set up. A smaller experimental reactor is being built in Karlsruhe to test the fuel elements for the fast breeder. Plans are also going ahead for the construction of larger fast breeder reactors in collaboration with France. German electricity supply companies are involved in the construction of the French Super-Phénix, for which they are receiving a grant of DM55 million from the West German government.

The Ministry of Research and Technology is in charge of all government activities in the field of fast breeder development, and although there is growing opposition to these reactors in parliament, the Ministry apparently intends to continue promoting intensive research on them. So far the government alone has spent DM2,100 million on the development of fast breeder reactors. In addition to the prototype at Kalkar, a large fast breeder reactor is scheduled to be built in the early 1980s. Its construction will take into account the results of the French project; there has been close cooperation between France and West Germany on fast breeder development since the treaty between the two countries in 1975.

In 1977 space research will receive DM600 million almost exclusively from the government, and in particular from the Ministry of Research and Technology: DM347 million will go to the European Space Agency and form the major part of West Germany's spending on space research. At the moment the West German government is primarily involved in financing the ESA Spacelab and in the development of various exploratory satellites. It gives DM 40 million a year towards developing the launcher Ariane; an extra DM 10 million will go towards the building of a launching base for the Ariane in Kourou in French Guiana.

Support for national space projects has decreased steadily in the past few years and now only 20% of the total expenditure goes on domestic projects. In 1977 DM133 million will be spent on a large research establishment for air and space travel, Deutsche Forschung-und Versuchsanstalt für Luft und Raumfahrt (DFVLR). ☐

SWEDEN

A catalytic note

Wendy Barnaby reports from Stockholm on Sweden's recently established Energy Institute

SWEDEN'S new international Energy Institute, opened recently in Stockholm, is planning to carve a niche for itself in research on energy/ecology problems. It will see man's use of energy as a special case of the energy flow in the biosphere, affecting it and all natural resources. This should be a suitable focus for the new Director, Professor Gordon Goodman, a British ecologist with wide experience in energy research, and it is in line with the interests of the chairman of the international board, Professor Jack Hollander, an American who heads a large project on energy for the US Academy of Science.

Specific research projects will depend largely on the results of the review of current energy research that Goodman and a plasma physicist, Lars Kristoferson, are about to begin—both want energy researchers to notify them of projects being done. The idea is to close those gaps created by the transdisciplinary nature, long time-scale or low economic interest of the work needed to fill them. The Institute will not therefore be interested in short-term, controversial topics; Goodman wants to establish its reputation as a trusted supplier of timely and significant facts for the international debate on energy-related problems. He envisages the Institute playing a catalytic role by preparing review papers highlighting the need for research in various areas. As it has no laboratory facilities, its work will be carried on by seminars, symposia and publications.

The Institute's funds are very limited—about $400,000 a year for the next seven years from the private Beijer Foundation—and additional funds will have to be sought elsewhere to get a reasonable programme going. But Goodman points out that the money has no strings attached and will enable the Institute to avoid projects meant to bolster sectarian interests. Because of the financial limitations, permanent positions will probably be limited to the Director and his assistant; academics coming to Stockholm for short visits or sabbaticals would help carry out projects. ☐

IN BRIEF

JET meeting

The Committee of Permanent Representatives (COREPER) in Brussels, made up of senior officials of the EEC member states, meets this week to discuss the ill-starred joint fusion project, JET. If they can resolve the outstanding problem of the method by which the proposed JET council will work, the way will be clear for an early Council of Ministers meeting to finalise the question of the site, which is expected to be either Garching in Germany or Culham in England.

Argentinian disappears

The latest Argentinian scientist about whom concern is being expressed is Horacio Dottori, an astrophysicist. Sr Dottori was at the Cordoba Astronomical Observatory from 1967 to 1976 except for a two-year period in Germany at the Max Planck Institut für Physik und Astrophysik from 1971–73. He worked on observations of peculiar and interacting galaxies. In March 1976, following the military takeover, he was dismissed. He was arrested in August 1976 and has now disappeared; his friends believe he has been sent to a camp called 'La Perla', about which little is known.

X-ray survey

To meet the requirements of a directive on radiological protection from the EEC Council of Ministers, and because existing information in Britain is out of date, the UK National Radiological Protection Board (NRPB) is to conduct a survey, beginning in June and encompassing over 100 National Health Service hospitals, of the radiation doses which patients receive from the diagnostic use of X-rays.

The medical use of radiation contributes some 13% of the total dose which the population receives, making it the largest man-made component. Natural background radiation contributes some 84%. The specific objective of the survey is an estimation of the so-called 'genetically significant dose' (GSD) to the population arising from diagnostic radiology.

Chemistry PhD survey

The Chemical Society's Standing Advisory Committee on Relationships between Higher Education and Industry (SACRHEI) recently completed a survey on US views of the British chemistry PhD. It sought the opinions of 40 US industrialists, seven US professors of chemistry and a couple of professional associations. Although about half the industrialists and academics thought the British and American PhDs comparable so far as research is concerned, the industrialists thought holders of British chemistry PhDs were less motivated towards employment in industry and had less appreciation of overall industrial problems than their American counterparts.

Consumer revolt

THOMAS H. JUKES

THE ban on saccharin proposed by the Food and Drug Administration (FDA) has unleashed a public reaction of unexpected, and allegedly unprecedented, intensity. The protest against the ban was apparently expected to last for only a few days and, accordingly, the US manufacturer of saccharin announced plans to discontinue production. After a week, these plans were cancelled because of the heavy and continuing demand for saccharin by consumers who were stockpiling it in various forms. This must have been a great surprise to those who thought that mere mention of carcinogenesis would make the public abjure saccharin.

I have received copies of about 150 US newspaper articles on the ban. The FDA came in for a tremendous clobbering, even though its action was mandatory under provisions of the Delaney Clause of the Federal Food Drug and Cosmetic Act. In former days, those who objected to the Clause were often rebutted by *ad hominem* accusations, as for example by Epstein (*Preventive Medicine* **2**, 140, 1973):

> All such criticisms [of the Delaney Clause] have emerged from industrial groups, trade associations and their consultants, and from groups that are clearly identified with protection of industrial interest . . . Such 'captive' spokesmen [are characterised by] lack of expertise and national recognition in the field of chemical carcinogenesis . . . No such criticisms have emerged . . . from qualified scientific representatives of citizen, consumer and public interest groups.

In the face of such invective, a symposium on the Delaney Clause, held by the New York Academy of Sciences in 1973, did not produce a single proposal for its revision. Banning saccharin seems to have changed the picture. As a columnist said, "It wasn't large corporation people who swept through supermarkets, cleaning the shelves of artificially sweetened products".

The FDA, perhaps intentionally, noted that "a human would have to drink 800 12-ounce cans of diet soda a day for a lifetime" to ingest an amount of saccharin comparable to that received by rats in the Canadian study that led to the ban. In vain did FDA point out that one can daily would still impose a proportionately lesser risk. Cartoonists, columnists, and lawmakers swooped down gleefully on the 800-can statistic. One cartoon showed a pharmacist offering a frustrated saccharin customer cigarettes and whisky as an alternative for the banned sweetener. A congressman sought fleeting fame by introducing a bill to prohibit giving saccharin to rats. "Science For The People" had taken over, but not in the way that its sponsors had originally planned. A few stern hard-liners told diabetics to stop griping, and drink water, a sort of Marie-Antoinette-in-reverse suggestion that was not well received.

Public rebuff of the Delaney Clause received support from eminent clinicians who said they had seen practically no cases of bladder cancer in diabetics who had been on saccharin for many years, thus implying that rats responded differently from human beings. Thus the two cardinal points of the Delaney Clause: extrapolation of carcinogenesis from laboratory animals to human beings, and the absence of a threshold, both were widely discounted. The Delaney Clause may well need revisions. However, let us hope that opposition to banning saccharin will not jeopardise a programme to reduce exposure to environmental carcinogens.

As of last reports, the FDA was still answering telephone calls, but Congressman James Delaney could not be reached.

Rights of scientists

SIR,—You quote the newly published report *Scholarly Freedom and Human Rights* (24 February, page 671) in stressing the responsibility of learned societies to support oppressed and persecuted scientists, by public protests. This is important: hitherto it has usually been argued that only non-scientific channels are permissible for such protests because actions taken by scientific societies would be political demonstrations not consistent with their high scientific aims.

Two points seem to be disregarded in this argument. Firstly, that protests through non-scientific channels emphasise the humanitarian aspect whereas the professional aspect is emphasised only through scientific societies. If a scientist is hindered or restricted in his work and prevented from normal communication and exchange with his colleagues within the international scientific community, not only is his own work impeded but also that of his colleagues and hence scientific progress in general. Secondly, that the governments that persecute scientists bring politics into science whereas the scientific societies submit their professional protests just to keep politics out of science.

It has also been argued that international societies should be particularly careful in such matters, whereas national societies might act more freely. However, there are good reasons for the view that an international scientific society is an appropriate channel for appeals and protests when scientists are arbitrarily cut off from the international forum of scientific discussion. The very purpose of an international scientific society is to promote science by fostering international collaboration, communication and exchange among scientists. A national society is involved in professional, educational and advisory activities, and the promotion of international cooperation, which is the main concern of an international society, is of but minor importance. If a member of an international society is prevented from normal communication and exchange with fellow-scientists in other countries, the very purpose of the society is violated and it is the duty of its board to take measures to restore the member to a normal scientific life. Although practical considerations may call for restraint and moderation while acting within an international body, it is important that the principle is made clear. It is the scientific and professional aspect of the matter that should be advanced in this context; political and other arguments should be avoided.

In conclusion, then, it is the duty of scientific societies to speak up officially in defence of oppressed and persecuted scientists.

The Tacoma Bridge collapse

SIR,—Dr Henry Chilver (10 February, page 494) reviewed a number of accidents and attempted to categorise them by making use of a 'triangle of failures'. The failure of the Tacoma Bridge in 1940 lies in Chilver's diagram midway between 'unknown environmental forces' and 'unpredictable behaviour' and he says that "The cause of the accident was an inadequate understanding of the interaction of the structure with its environment, leading to large oscillations of the bridge. The resulting behaviour was unpredictable at the time . . . ". There were however indications in information available at that time, but not collated then, that a failure would occur and that the mode of failure was not new. The figure shows variation of span length, L, of a suspension bridge, with the year of building. Also shown are corresponding values of the ratio of girder depth, d, to span length (some examples are missing because records are incomplete); this parameter is a rough measure of the stiffness of the girder against vertical loads from wind or traffic. In the 19th century, bridges were designed on an intuitive basis and several were destroyed or damaged by winds. In one or two instances, eye witness reports were recorded and these bear remarkable similarity to the observations recorded on film during the collapse at Tacoma. The earlier collapses consistently occurred whenever d/L was less than approximately 0.006.

At the turn of the century a new theory was developed which seemingly gave mathematical rigour to the design of the deck girder. This theory considered only static wind pressure loading but, for the heavy, deep girders then currently fashionable, it proved very successful and no dynamic behaviour was observed. During the next thirty years several suspension bridges were built and, with the confidence instilled in the designers by the availability of the theory, there was a trend to much lighter girders (d/L). Economy, lower traffic loads and aesthetic appeal were the main driving forces in this move. Eventually, as the figure shows, the values of d/L dropped below 0.006 and wind induced oscillations were observed in a number of bridges, although only the Tacoma Bridge actually collapsed. After that deck girders were made stiffer, but the pattern of development was quickly re-established. (This time, however, the critical value of d/L has been safely reduced because of the use of wind-tunnel testing in conjunction with the design calculations).

Had proper records been kept of trends in bridge design, and had engineers been made aware of earlier wind-induced failures, a warning would have been sounded on the dangers of using the analysis for very light deck girders. We have shown that the failures of other bridges of different types could also have been avoided if records had been kept of design trends and minor accidents preceding the major event had been adequately investigated. Similar trends have been noted in structures other than bridges. We suggest the need for a facility to gather and process information on which to base the direction of research on structural behaviour.

news and views

Another optical pulsar

from Jocelyn Bell Burnell

EVER since the discovery of optical flashes from the pulsar in the Crab Nebula and the association of pulsation in this band with rapid pulsation period, astronomers have expected that the Vela pulsar, the third fastest, should likewise emit pulses of light. But in the 8 years since that initial discovery hope has gradually faded as larger and larger telescopes have searched for fainter and fainter flashes. So far had faith dimmed that consideration was recently given to the unpulsed optical emission of the pulsar, and an attempt made to pick out the candidate star on the basis of predicted magnitude and colour (Lasker *Astrophys. J.* **203**, 193; 1976).

But at last, optical pulsations have been found. In this issue of *Nature* (page 692) Wallace and eleven others (in a paper with more authors than paragraphs) report the detection of optical pulsations from the Vela pulsar. In a collaborative effort between optical astronomers from the Royal Greenwich Observatory and the Anglo-Australian Telescope, and radio astronomers in Australia, faint optical pulses at the same pulsation period as the radio pulses have been recorded. With a time-averaged magnitude of 25.2 this is the faintest thing ever seen (and in good agreement with Pacini's prediction that it would have magnitude about 25 (*Astrophys. J.* **163**, L17; 1971)).

The Vela pulsar has been a particularly troublesome pulsar to deal with. Not only are the light pulsations weak, requiring a large modern telescope such as the AAT with sophisticated equipment for analysis, but the pulsation period of the pulsar itself, as observed by the radio astronomers, is not stable. Pulsars are believed to be rotating neutron stars—stars of a few kilometres radius with a density comparable to that found in the atomic nucleus. The pulsation period is the rotation period, which in the case of the Vela pulsar is 80 ms. The period gradually lengthens as the star loses rotational energy, and, again for the Vela pulsar, this is about 11 ns per day. This is typical pulsar behaviour, although for both the Crab and Vela pulsars the rotation rates are much faster than average and the slowing more noticeable. What is peculiar to the Vela pulsar and partly responsible for the delay in the discovery of the light flashes is the occasional large hiccough or "glitch" of the pulsar, when its rotation rate suddenly increases (typically by 200 ns). The position of a radio pulsar is obtained by the radio astronomers from a study of the Doppler shifts in its pulsation period due to the annual motion of the Earth about the Sun. Erratic behaviour of the pulsar period upsets the determination and uncertainties in the position of this pulsar have not helped the optical astronomers.

The region around the Vela pulsar, PSR 0833-45, is complex. There are many faint stars, and the remains of a supernova—a star that exploded cataclysmically blowing off a shell of material. The pulsar, which may have been formed by the supernova explosion, lies within part of this shell—the part called Vela X by radio astronomers. To add confusion to complexity there are two X-ray sources in the constellation of Vela, Vela X-1 (3U0900-40) and Vela XR-1 (3U0833-45). Vela X-1 shows strong X-ray pulsations whereas Vela XR-1 which is presumably associated with the pulsar does not!

According to Pacini's predictions the pulsated X-ray emission from 0833-45 should be below the threshold of present X-ray telescopes, but γ-ray astronomers have had noticeable success in detecting this pulsar. (The division between X and γ-ray astronomy is made on the basis of photon energy, the divide being around a few hundred keV, and is independent of the method of production of the photons.) So successful have been the γ-ray astronomers (with the COS B satellite, for example), that one wonders whether it might not be reasonably strong in X rays too. It will be interesting to learn more about the X-ray source: where it is in relation to the pulsar, what it is, and what fraction of the X-ray emission is pulsed.

It is tempting to assume that the Vela pulsar is similar to the Crab only less energetic: both are rapid pulsars, both emit pulses at the radio pulse period over a wide range of the electromagnetic spectrum and at γ-ray energies their pulse profiles are strikingly similar. But there are striking differences too, notably that whereas for the Crab the radio, optical, X- and γ-ray pulses are all in phase, in the Vela pulsar the radio pulse apparently precedes the optical and γ-ray pulse.

One is reluctant to divide a sample of two into two separate categories, and, unfortunately, there are unlikely to be many more samples on which to establish such a division. This makes this discovery and the consequent observations all the more important. ☐

Correction

Changes in proof to the article by Roberts and Falkow in last week's *Nature* (**266**, 630; 1977) require the following correction to be made to the accompanying comment in *News and Views* (**266**, 586; 1977). In paragraph 3 it is stated that the 25 Mdal sex-factor plasmid has not yet been found to be transferred to recipient strains along with the drug resistance plasmid. Roberts and Falkow have now found that it is transferred to recipient strains of *Neisseria gonorrhoeae*.

Synaptic memory in the hippocampus

from Shin-Ho Chung

IT has been known for some time that efficiency in synaptic transmission can be enhanced for several hours after presynaptic fibres have been briefly stimulated. Interest in this phenomenon, known as 'long-lasting potentiation', is partly due to the belief that such a change in synaptic efficiency may well be a neurophysiological mechanism for storage of information in the central nervous system. While most physiological studies on synapses have emphasised events occurring immediately after the arrival of a nerve impulse, psychological observations reveal many phenomena which must be due to long-lasting effects of nerve impulses on synaptic pathways. Amongst these are the after-effects of intense sensory stimulation, which may persist for many days, as well as conditioned reflexes, and the process of learning; all these are almost certainly due to long-lasting changes in the properties of neurones and synapses brought about by use and disuse. A number of recent studies are aimed at elucidating the underlying mechanisms of synaptic plasticity.

Long-lasting potentiation in a mammalian synaptic pathway was first discovered by Larrabee and Bronk (*J. Neurophysiol.* **10**, 139; 1947) and was later confirmed by Lloyd (*J. gen. Physiol.* **33**, 147; 1949). In a simple synaptic pathway where the presynaptic axons connect directly to the postsynaptic neurones, they noted that transmission through the pathway is greatly enhanced for several minutes following a brief period of repetitive stimulation of the presynaptic axons. The duration of this facilitation could be extended for up to 2 hours by stimulating the pathway at an optimal frequency (Beswick & Conroy *J. Physiol. Lond.* **180**, 134; 1965). Bliss and Lømo (*J. Physiol. Lond.* **232**, 331; 1973) later extended this observation to the hippocampus, which proved to be a particularly suitable structure for electrophysiological analysis of synaptic plasticity. Cells there form tightly packed layers, with their dendrites oriented radially, and afferent inputs originating from different regions of the brain terminate at discrete segments of the dendrites (see diagram on page 738 of this issue of *Nature*). Brief episodes of repetitive stimulation to the perforant path fibres, which link the entorhinal cortex with the granule cells of the hippocampus, produce a cumulative increase in the amplitude of the responses evoked by subsequent single stimuli. Compared with the spinal cord (Lloyd *op. cit.*; Beswick & Conroy *op. cit.*), the duration of synaptic potentiation in the hippocampus is prolonged, and the degree of facilitation pronounced. For example, a few brief trains of repetitive stimulation increase the amplitude of the synaptic potential by as much as 300% and this enhanced synaptic efficiency persists, in certain conditions, as long as several weeks (Bliss & Gardner-Medwin *J. Physiol. Lond.* **232**, 357; 1973). Since these initial reports, the phenomenon has been confirmed in various mammalian species and in two other hippocampal pathways (Deadwyler *et al. Brain Res.* **88**, 80; 1975; Douglas & Goddard *Brain Res.* **86**, 205; 1975; Schwartzkroin & Wester *Brain Res.* **89**, 107; 1975; Dudek *et al. J. Neurophysiol.* **39**, 384; 1976).

An unresolved question, which Anderson *et al.* (page 736 of this issue of *Nature*) and Lynch *et al.* (page 737) have sought to answer, is whether the enhanced synaptic efficiency seen in the conditioned pathway is due to a generalised increase of sensitivity in the postsynaptic neurones, or whether it is confined to those synapses which have been repetitively activated (or tetanised). Although the findings reported by the two groups differ in detail, it is now satisfactorily established that a prolonged increase in synaptic efficiency is confined to the tetanised pathway, suggesting that the underlying processes giving rise to the hippocampal potentiation may differ from those responsible for the heterosynaptic facilitation which occurs in certain invertebrate neurones (Kandel & Tauc *Nature* **202**, 145; 1964; *J. Physiol. Lond.* **181**, 1; 1965). Andersen and his colleagues report that a tetanus applied to one group of afferents causes no change in synaptic transmission in the untetanised pathway, while Lynch and his coworkers claim that the enhanced synaptic efficiency in the tetanised pathway is accompanied by a generalised depression of the postsynaptic neurones. This latter result is consistent with their previous finding that the sensitivity of pyramidal cells to iontophoretically applied glutamic acid is decreased after tetanus (Lynch *et al. Nature* **263**, 151; 1976). While the conflicting observations reported by the two groups are difficult to reconcile, they are only tangential to the ultimate aim of the investigation, which is to localise the changes in the properties of neurones and synapses caused by use and disuse, and to understand the ways in which these changes are induced.

There are a number of possible mechanisms which may be responsible for long-lasting potentiation (see Bliss & Lømo *op. cit.*). For example, an impulse flowing down the previously tetanised pathway may invade more terminals than normal, thereby producing a larger effect on its target cells (see *News and Views, Nature,* **264**, 313; 1976). Alternatively, and this is the possibility which Andersen *et al.* favour, the same number of terminals may be activated but each terminal may liberate an increased amount of transmitter. Finally, it is also possible that previous activity may increase the sensitivity of the postsynaptic junctional membrane; for example, Rall (*Biophys. J.* **2**, 145; 1962), among others, has postulated that a structural alteration of the postsynaptic spines may be an important variable in changing the relative weights of synaptic inputs. The swelling of the spines, due to the uptake of electrolytes and water, can cause a reduction in the resistance of the narrow stems by which the spines are attached to the parent dendrites, and this could provide a basic mechanism for long-lasting potentiation in this monosynaptic pathway. In this context, it is relevant to note that the diameter of spines in the hippocampus appears to increase abruptly when the pathway innervating them is tetanised (van Harreveld & Fifkova *Anat. Rec.* **181**, 355; 1975; *Expl Neurol.* **49**, 736; 1975).

The molecular basis for long-lasting potentiation will remain speculative until synaptic transmitters in the central nervous system are identified, and this is proving an elusive task. An excellent study in the amphibian sympathetic ganglion, where the synapses are known to be mediated by acetylcholine, has demonstrated that a slow decrease in membrane conductance, triggered by muscarinic receptors, causes potentiation of synaptic responses generated by the activation of nicotinic receptors (Schulman & Weight *Science* **194**, 1437; 1976). Athough the mechanism of potentiation in the hippocampal pathways may not be the same as in the amphibian sympathetic ganglion, it is this type of controlled study which is now needed for cortical cells. Once the underlying mechanism governing plasticity observed in the simplest synaptic system is elucidated, experimental investigation can then be extended to the more complex polysynaptic pathways and, finally, to the grey matter of the cerebral cortex. This ultimate aim, however, will not be achieved in the near future. As Ramón y Cajal once remarked, the structure of the cerebral grey matter is so intricate that it defies and will continue to defy for many decades the obstinate curiosity of neurobiologists. □

Anti-anxiety receptors in the brain?

from Leslie Iversen

LIGAND binding techniques are well established as important tools for studies of a variety of biological receptors for peptide hormones and neurotransmitter substances. In most cases such assays have been developed to investigate receptors for which the naturally occurring ligand is already known, for example, insulin, acetylcholine or noradrenaline. In the case of the opiate receptor, however, the discovery of the high affinity binding of radioactively labelled morphine-like drugs to membranes in brain homogenates (Pert & Snyder *Science*, **179,** 1011; 1973) was of a different character, since it allowed description of the precise characteristics and distribution of a receptor mechanism for which no naturally occurring ligand was then known, and it offered a powerful tool for the subsequent discovery of the enkephalins and endorphins as a new class of naturally occurring agonists for a receptor mechanism hitherto described only in terms of the organism's response to opiate drugs.

Such drugs, however, represent only one of several important classes of centrally acting drugs whose pharmacological mechanisms remain obscure. Squires and Braestrup (page 732 of this issue of *Nature*) now describe their preliminary results in applying a similar rationale to studies of the receptor mechanisms possibly involved in mediating the actions of minor tranquillisers of the benzodiazepine class. These drugs, exemplified by the anti-anxiety agent diazepam (Valium) and the hypnotic drug nitrazepam (Mogadon), have had an enormous commercial success since the discovery of their remarkable psychopharmacological properties in the 1950s. They, and many related analogues in the benzodiazepine series, are able to tame otherwise aggressive laboratory animals, they exhibit CNS muscle relaxant properties, and in man the drugs are used as anticonvulsants and more importantly as anti-anxiety agents. At higher doses they are also effective hypnotics, and since they are much less toxic than barbiturates, have taken an increasing share of the large market for those suffering from anxiety and/or insomnia. Benzodiazepines, needless to say, have been consumed by many millions of people in the industralised nations of the world in which such complaints are endemic.

Despite their unique pharmacological properties and widespread medical use, the mode of action of the benzodiazepines remains unknown. There have been various attempts to explain their effects in terms of current neuropharmacological fashion, that is, by action on CNS catecholamine or indolamine transmitters, but these have been largely unconvincing. Young *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **71,** 2246; 1974) found that the potencies of a series of benzodiazepines in displacing radioactively labelled strychnine from binding sites associated with glycine receptors in mammalian spinal cord correlated fairly well with the potencies of the same drugs in various animal behaviour tests predictive of anti-anxiety properties, and these authors proposed the hypothesis that the drugs might interact with receptors for this inhibitory amino acid transmitter in CNS. However, relatively high concentrations of the drugs were needed to show this effect and subsequent neurophysiological experiments failed to lend support to this hypothesis (Curtis *et al. Brit. J. Pharmac.* **56,** 307; 1976). A more recent proposal has been that the benzodiazepines might in some way mimic or enhance the effects of another inhibitory amino acid transmitter, γ-aminobutyric acid (GABA) at CNS receptor sites. This hypothesis was based on both biochemical and neurophysiological evidence (Polc *et al. N. S. Archiv. Pharmac.* **284,** 319; 1974; Costa *et al. Adv. Biochem. Psychopharmac.* **14,** 113; 1975), and has attracted a wide following. Nevertheless, it has proved difficult to demonstrate any direct interaction between benzodiazepines and GABA receptors, although recent neurophysiological evidence has shown that these drugs are able to exert inhibitory effects on the firing of single cells in rat brain similar to those seen on application of GABA (Dray & Straughan *J. Pharm. Pharmac.* **28,** 314; 1976).

Squires and Braestrup found that high specific activity ^{3}H-diazepam is bound to saturable sites in rat brain membrane preparations with very high affinity—half saturation being achieved at a drug concentration of only 2.6 nM. When low concentrations of the labelled drug were used more than 90% of the total binding was attributable to this single class of high affinity sites. More importantly, they showed that the potencies of 21 different non-radioactive benzodiazepine drugs in competing with labelled diazepam for binding showed a highly significant correlation with the known pharmacological potencies of these drugs determined previously in various animal tests known to be predictive for anti-anxiety properties in man. The potencies of the drugs tested in both the *in vivo* and *in vitro* tests ranged over four orders of magnitude. On the other hand, none of the known amine or amino acid transmitters (including glycine and GABA), or any of the drugs known to interact with their receptors, had any inhibitory effects on ^{3}H-diazepam binding. Other minor tranquillisers, such as meprobamate, barbiturates or ethanol, were also ineffective as inhibitors, as were opiate drugs.

The authors therefore, claim to have described a saturable high affinity binding mechanism whose pharmacological specificity suggests that it may have some important relation to the mode of action of the benzodiazepines in whole animal experiments or in man. It is also interesting to note that the highest density of ^{3}H-diazepam binding sites was found in the frontal and occipital cortex of rat brain, areas not known to be enriched in any of the known transmitter substances.

If their hypothesis is correct, and caution is certainly still needed in extrapolating from these preliminary biochemical results, their findings may have a major impact on our future understanding of the mode of action of this class of psychotropic drugs. By analogy with the discovery of the opiate receptor, the benzodiazepine receptor assay may even offer a simple means for the discovery of the naturally occurring ligand for such receptors—the brain's own anti-anxiety substance? Further developments in this field will certainly be awaited—anxiously.

A hundred years ago

AT the last meeting of the French Anthropological Society, a long report was read which showed that Druidism was not quite extinct in Britanny, some country people still adhering to Pagan practices in spite of the priests' exertions. It was noticed that the clergy were anxious to destroy menhirs and other similar relics. A petition has been sent to the ministry to put a stop to this iconoclastic zeal.

SIN and the muon-electron puzzle

from F. E. Close

DURING the past few weeks several papers have appeared proposing mechanisms to explain the exotic radiative transmutation of the muon into the electron. Although widespread publicity in the world press may have led readers to think that this 'forbidden' decay has been seen (hence the sudden flux of theoretical papers) no one involved in the experiment at the Swiss Institute for Nuclear Research (SIN) in Zurich has yet claimed to have solid evidence for it. Indeed, the group concerned are still quoting a limit consistent with no such decays at a level of about one part in a hundred million of all muon decays. The rumours, and source of the press reports, were that a signal was being seen at the level of order one part in 10^9. However, there are experimental questions still to be settled, for example, the energy and angular resolutions which limit conclusions at present: hence the present claim only of a limit.

Why all the fuss? The reason is that for over a quarter of a century the muon has remained a mystery. So far as we know the Universe could have existed without a muon at all, and our everyday experiences in such a Universe would have been the same as in the real world (apart from esoteric phenomena like the pion lifetime). Yet for some reason nature is not satisfied with the electron and its associated neutrino and has repeated itself by invoking two more leptons (the muon and its neutrino).

The muon is identical to the electron in all respects except that it is about 200 times as massive. The question 'why does the muon weigh?' has remained unanswered for 30 years. No evidence for a new interaction possessed by the muon has been found, which would explain its larger mass and distinguish it from the electron. In all respects the muon appears to be simply a heavy electron and yet does not decay radiatively into one. It seems that the muon remembers that it is a muon partnered with its own neutrino and so

$$\mu^- \rightarrow \nu_\mu + (e^- + \bar{\nu}_e)$$

occurs but decay modes like $\mu^- \rightarrow e^-\gamma$, $e^-e^+e^-$ and so on are not seen. A rule was therefore invented to dignify these observations: muon number (possessed only by the muon and its neutrino) is conserved in nature. Beyond this little or no progress was made.

Key

γ,	photon
Leptons	
e,	electron
e^+,	positron
ν_e,	electron neutrino
$\bar{\nu}_e$,	electron antineutrino
μ,	muon
μ_e,	muon neutrino
$\bar{\mu}_e$,	muon antineutrino
Hadrons	
p,	proton
Λ,	lambda
π,	pion
K,	kaon
D°,	neutral charmed meson

Early searches for the radiative decay $\mu \rightarrow e\gamma$ were made and Pontecorvo and Hincks found a limit of a few per cent of all decays. Over the years this limit has been greatly improved and today stands at the level of one part in a hundred million. In principle experiments currently in progress at SIN in Zurich and at TRIUMF in Canada will either see a signal or place new limits of order one part in a thousand million. There are reports of an experiment planned at Los Alamos, New Mexico, which may be able to go down to a sensitivity of 1 part in 10^{10}.

The dramatic significance of these limits may be appreciated when one realises that only the known muon decay mode $\mu \rightarrow e\nu\bar{\nu}$ is a typical weak interaction. Hence one is failing to see $\mu \rightarrow e\gamma$ (naively an electromagnetic transition) at less than one hundred millionth of a weak decay rate (this latter being the weakest interaction apart from gravity that is known to exist). Hence, if there are any undreamt of subtle effects in the weak interactions then it may well turn out that they will show up first in the $\mu \rightarrow e\gamma$ amplitude.

Gauge theories and massive neutrinos The discoveries of charmed particles and their intimate relation with the gauge theories have painted a clear and beautiful picture of nature. An intimate deep relation has been noticed between the lepton world and the quark world, more specifically the ($\mu\nu_\mu$) pair *vis à vis* the ($e\nu_e$) pair in the leptons on the one hand and the charmed–strange quark pair *vis à vis* the up–down quarks in the hadron world on the other. In the future this may point towards a unification of leptons and quarks (or weak–electromagnetic and strong interactions!). At present it has made theorists think again about the role of the muon in nature's scheme—why it exists and why it does not decay radiatively into the electron. To appreciate these ideas it is useful first to describe the salient points of the current theory and then describe the new ideas on the application to the muon and its decays.

The carriers of the electromagnetic and weak interactions are the photon and the W boson respectively. When these fields interact with leptons or with quarks they can cause transmutations only within the left-handed doublets of

$$\text{leptons: } \begin{bmatrix} \nu_e \\ e \end{bmatrix} \begin{bmatrix} \nu_\mu \\ \mu \end{bmatrix} \text{ and quarks: } \begin{bmatrix} u \\ d' \end{bmatrix} \begin{bmatrix} c \\ s' \end{bmatrix}$$

Quarks d, s with well defined mass (eigenstates of the strong interactions) are linear combinations of the d′ and s′

$$d' = d\cos\theta + s\sin\theta$$
$$s' = -d\sin\theta + s\cos\theta.$$

It is as if the strong interaction world is rotated by a small angle θ (the Cabibbo angle) relative to that of the weak interactions. Hence the weak interactions can, and do, cause transitions between the (ud) quark doublet and the (cs) doublet. It is by this 'leakage' that the Λ beta decay, $\Lambda \rightarrow pe\bar{\nu}_e$ occurs and by which the charmed particles decay

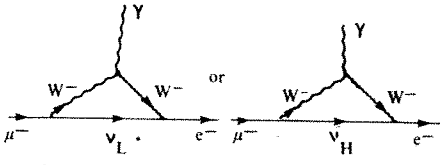
$$\begin{cases} c \rightarrow s' \equiv s\cos\theta - d\sin\theta \\ D^\circ(c\bar{u}) \rightarrow K^-(s\bar{u})\pi^+ \end{cases}$$

This mechanism for charmed decay is known as the GIM mechanism (see *Nature* **262,** 537; 1976) due to S. Glashow, J. Iliopoulos and L. Maiani. Is there an analogous mixing and GIM mechanism for the lepton doublets? In principle the answer is yes, and a consequence is that a leakage from muon world to electron world can arise leading in particular to the radiative decay $\mu \rightarrow e\gamma$. How does this come about?

Suppose that the two neutrinos have different masses. Then we can define ν_L and ν_H for the lighter and heavier respectively and these will play the part of the d and s quarks. The partners of the electron and muon in weak interactions will be defined as ν_e and ν_μ (these playing the part of the d′ and s′ quarks). Then analogous to the quark system the $\nu_{L,H}$ may be orthogonal mixtures of ν_e, ν_μ.

$$\nu_e = \nu_L\cos\ + \nu_H\sin\varphi$$
$$\nu_\mu = -\nu_L\sin\varphi + \nu_H\cos$$

the decay $\mu \rightarrow e\gamma$ can then proceed for instance by the processes



If the L and H neutrinos have the same mass (in particular being both massless) then there is exact cancellation between the two and the decay mode vanishes. However, if there is a mass difference then the amplitude is finally proportional to $m_H - m_L$ scaled by m_W, the mass of the W boson.

The W boson is believed to have a mass of around 60 GeV. The mass difference of the two neutrinos is at most some 650 keV (it could even be zero) and so the predicted rate can at most be

$$(\mu \to e\gamma)/(\mu \to \text{all}) \lesssim 10^{-25}$$

which is far below the present limits.

New heavy leptons

In the light of the above, what price must we pay if the decay were found at a level of 1 in 10^9 or so? This could have been accommodated in the above arguments if the heavy neutrino has a mass of several GeV, far in excess of the known limit. Could there be further heavy leptons in nature which could help in this respect? There is now good evidence for a heavy charged lepton τ around 2 GeV in mass, probably accompanied by a neutral ν_τ. The latter has a mass less than 700 MeV (Perl *Phys. Lett.* **63B**, 466) and so cannot be of use in the present context. However, this discovery does release one's inhibitions and shows that a whole new spectroscopy of heavy leptons is not necessarily absurd.

If such further heavy leptons indeed exist then the $\mu \to e\gamma$ decay can arise and several mechanisms have been suggested. One way is to have right handed doublets involving new neutrals and the electron or muon. With the massive neutrals introduced this way the previous game can be played and a sizeable $\mu \to e\gamma$ decay accommodated. This idea has been proposed by T. Cheng and L. Li in the USA. An interesting by-product could arise in connection with the failure to see parity violation in atoms. Parity violation occurs if the electron (muon) only takes part in left handed weak interactions. If the electron (muon) now also couple to heavy neutral leptons in the right handed mode, parity can be conserved. (Of course, parity will still be violated in neutron β decay as the neutron–proton mass difference is so small that only the electron and its massless left-handed neutrino can be produced). In a similar vein, F. Wilczek and A. Zee of Princeton University have proposed doubly charged heavy leptons to generate the μ decay.

Before we conclude that the observation of $\mu \to e\gamma$ would force us to deduce that heavy leptons exist we should notice a proposal of J. Bjorken and S. Weinberg of Stanford, California. In the gauge theories, particles gain masses by coupling to scalar fields known as Higgs particles. The coupling of the Higgs particles to fermions can generate contributions to weak interaction decay rates. However this is usually ignored since the coupling is proportional in strength to the masses of the fermions concerned, and the electron and muon are very light. In rare and ultrarare decay processes these couplings could turn out to have important phenomenological consequences. Furthermore, Bjorken and Weinberg noted that in the standard Weinberg–Salam gauge theory one can have a naturally occurring coupling of a Higgs particle, a muon and an electron all at one point and hence generating the transition $\mu \to e\gamma$ without extending the number of leptons in nature beyond the famous four.

Before the advent of gauge theories an observation of $\mu \to e\gamma$ would have left us puzzling as to how to proceed. With the great advances of the past few years not only do we know how to tackle the problem but even have several solutions in advance of any signal! Perhaps none of the models is very suasivious. However, if a signal is seen in the current experiments then one must take these ideas seriously and more impressive support for the gauge theories will have been unearthed. That this will happen in the next month or two is many theorists' midsummer night's dream—but it could turn out to be much ado about nothing.

Spin waves in superfluid ^{3}He

from P. V. E. McClintock

ONE of the most intriguing features of the recently discovered superfluid phases of liquid ^{3}He is that in sharp contrast to ^{4}He, the only other superfluid known in nature, they have magnetic properties. It is hardly surprising, therefore, that efforts to understand superfluid ^{3}He have been influenced by making comparisons with more conventional types of magnetic material, attempting to explore both the similarities and the fundamental differences in their properties. One characteristic feature of ordered magnetic solids is that they may support so-called spin waves, a form of collective excitation among the magnetic elements. The possible existence of spin waves in ^{3}He has consequently been a subject of much discussion during the four years which have elapsed since the superfluid phases were discovered by D. D. Osheroff, then working at Cornell University. It is of particular interest, therefore, that Osheroff and his coworkers at Bell Laboratories have now reported (*Phys. Rev. Lett.* **38**, 134; 1977) the first experimental observation of spin waves in the B phase of superfluid ^{3}He.

The magnetism of liquid ^{3}He arises from the magnetic moments carried by the nuclei of the ^{3}He atoms. In ordinary normal liquid ^{3}He in the absence of a magnetic field the nuclei are so weakly coupled to each other that the liquid is completely devoid of any overall magnetic order. When the liquid is sufficiently cooled, however, things become very different: the onset of long range order at the superfluid transition temperature involves the orientation of nuclear spins in definite directions, producing just the sort of ordered magnetic structure which might be expected to support spin waves.

In the case of a magnetic metal, one of the most convenient ways of demonstrating the existence of spin waves is through use of a resonance technique to excite standing waves in a very thin layer of the material. The situation is somewhat analogous to the more familiar one of standing waves on a stretched string whose ends are fixed in position. Unlike the case of the string, however, it is not the position, but rather the direction of the spins which is fixed on the boundaries of the material and which varies coherently through its thickness. Absorption of energy takes place for radio waves of the right frequency to excite a standing spin wave, that is, one such that the thickness of the layer of metal is equal to an integral number of half-wavelengths. Thus, if the rate of absorption of electromagnetic radiation is measured while its frequency is gradually increased, a series of peaks will be seen corresponding respectively to the fundamental, and higher orders of standing spin waves being excited.

The Bell Laboratories group used what in many ways is a very similar technique in their search for spin waves in superfluid ^{3}He. The combination of a strong magnetic field and the presence of a solid surface was used to fix the spin anisotropy axis n, thus defining the directions of the spins at the surfaces of a series of thin laminae of liquid. These were formed between a set of 20 fused quartz plates each about 7×11 mm in area, spaced 210 μm apart. The magnetic field was applied in the plane of the plates. Under these conditions, although n tries to lie parallel to the magnetic field in the bulk liquid between the plates, it is compelled to take up a different fixed direction where the liquid touches the surfaces of the plates. The competition between these effects causes the direction of n to vary smoothly with position in a completely determined way between the plates. Spin waves consist, therefore, of coherent deviations from this equilibrium situation, and may be expected to reveal their existence, as in the case of the thin metallic film, through the resonant absorption of electromagnetic radiation at particular frequencies depending, in this case, on the temperature and on the magnitude of the applied magnetic field. The cell was placed in a compressional cooling apparatus in which the temperature of the liquid was lowered by reducing its volume and thus solidifying some of it, which was able to reach the so-called superfluid B phase which is stable below its transition temperature at about 2 mK.

In the event, a series of striking absorption peaks was indeed found approximately at the frequencies predicted by theory. Although the peaks were broader than ordinary NMR resonances in ^{3}He, they were quite well defined, thus eliminating the lurking possibility that spin waves in ^{3}He might be modes which are overdamped and therefore unobservable. As the authors point out, it is quite possible that the observed width of the resonance maxima is merely an experimental effect arising from small variations in the spacing of the quartz plates. The change with temperature of the resonant frequencies turned out qualitatively to be very much in line with theoretical expectations.

The experimental results are not, however, in close quantitative agreement with theory. However, although the authors' tentative explanation of the discrepancies (typically about 20%) may or may not be correct, there seems little doubt that they were indeed observing spin waves. Further experimental and theoretical work is clearly required, but it seems that spin wave resonance has now been added to the rapidly growing battery of techniques available for elucidating the dauntingly complicated properties of superfluid ^{3}He. ☐

Complementary genetics

from M. J. Hobart

An EMBO Workshop on Complement Genetics was held in Cambridge, UK on 18–22 March, 1977. It was organised by Dr P. Lachmann, MRC Group on Mechanisms in Tumour Immunity, Cambridge.

THE genetics of the complement system were put on the map, both chromosomally and as a topic of general scientific interest, by the discoveries in 1974 by F. H. Allen, S. M. Fu and their colleagues that the genes coding for Factor B and C2 are linked to *HLA*. This had been foreshadowed in 1973 by the work of P. Demant and colleagues showing that the Ss protein, coded within the *H-2* region of mice, was a complement component, subsequently shown by several groups of workers to be C4.

The complement system consists of at least 18 proteins, including proenzymes and inhibitors, whose activity is usually triggered by the binding of antibody to antigen. It is the major humoral effector system for the elimination of bacteria and viruses in vertebrates and is characterised by complex reaction pathways reminiscent of the clotting, fibrinolysis and kinin systems.

There is now good evidence that three complement components are coded by genes located within the *HLA* region: C2, Factor B and C4. The electrophoretic variants of C4 described by P. Teisberg (Ulleval Hospital, Oslo) show clear *HLA* linkage and both G. Mauff (Hygiene Institute, Cologne) and G. Hauptmann (Institut d'hematologie et de transfusion sanguine, Strasbourg) reported their methods which show the same phenomenon with rather improved resolution. These results confirm the earlier evidence for C4 linkage from studies of a deficient patient's family (C. Rittner, Institute of Forensic Medicine, Bonn). *HLA* linkage is now firmly established for C2 polymorphism (C. Alper, Center for Blood Research, Boston). The less common allele of *C2* (*$2C^2$* in the nomenclature proposed) was reported by T. Meo (Basel Institute for Immunology) to be in strong linkage disequilibrium with *HLA* BW15 and *HLA* CW3.

Alper also demonstrated polymorphism of C8 detected by isoelectric focusing and specific functional detection by haemolytic assay. There are at least three structural variants of C8, two of them common. The locus is not closely linked to *HLA*. Two new families with C8 deficient members were described by N. K. Day (Sloan Kettering Institute, New York) and F. Tedesco (Transplantation, Immunology and Blood Transfusion Service, Milan). In both families, there were totally C8 deficient individuals with different *HLA* types, showing that the deficiency genes also cannot be close to *HLA*. Furthermore it was apparent that there is difficulty in ascertaining the heterozygous deficiency states, since in both families, both parents of the propositi had C8 levels within the normal range. Furthermore Alper reported that members of a deficient family heterozygous for the structural variant could nevertheless have low C8 levels. This may explain the discrepancy between these reports and that of Merritt *et al.* (*Third International Workshop on Human Gene Mapping. Birth Defects* **XII** (7) 331, The National Foundation, New York, 1976) which claimed *HLA* linkage for C8 deficiency.

D. Glass (Robert B. Brigham Hospital, Boston) presented a large series of carefully measured cases of heterozygous C2 deficiency. There seems to be a significant association with juvenile rheumatoid arthritis and systemic lupus erythematosus in these patients. J. Soothill (Institute for Child Health, London) and J. Mowbray (St. Mary's Hospital, London) have evidence that there is an increased incidence of heterozygous C2 deficiency in infantile asthma and eczma. However, it was pointed out in discussion that apparently high recombination frequency between C2 and *HLA* observed by Glass is probably due to ascertainment errors inherent in measuring complement levels.

C3, C4, C5 and C8 are known to be composed of more than one polypeptide chain, but in no case is there any evidence that more than one locus is involved in coding for the observed polymorphisms. A possible explanation for this phenomenon is given by preliminary experiments of H. Colten (Children's Hospital Boston) and his colleagues (reported by Alper). They have shown that both C4 and C3 obtained from cell-free synthesis by immunoprecipitation occur as larger than expected chains. Their suggested interpretation of this result is that C3 and C4 (and, by analogy, perhaps C5 and C8) are synthesised as single polypeptide chains which are cleaved before secretion, rather like insulin. Only one cistron will then be involved in coding for the whole molecule and all markers will be alleles, irrespective of the chain on which they are found. Since there are now some 20 variants of C3, all of them apparently alleles, this view has its attractions. Some similar complement components seem to be the products of tandem duplicated genes. This is the case with C2 and Factor B. Both are linked to *HLA* in the same subregion and with no crossovers indentified between them. Both are single polypeptide chains, heat labile and form part of a complex C3 splitting enzyme. C6 and C7 are consecutively acting components and are both single polypeptide chains. They show close linkage to each other as demonstrated by allotyping (M. J. Hobart, MRC Group on Mechanisms in Tumour Immunity, Cambridge). Although C3, C4 and C5 are similar, C4 is linked to *HLA* but the other two components are not. If these molecules are the products of related genes, then they have been duplicated by processes other than (or additional to) tandem duplication.

A remarkable case of combined

subtotal deficiency of C6 and C7 was reported by P. J. Lachmann (MRC Group on Mechanisms in Tumour Immunity, Cambridge). The proband is in good health. The deficiencies of both components segregate together in the grandchildren, which is to be expected if the structural genes for both proteins are involved, since they are closely linked. Trace C6 and C7 activity appear in the proband's serum in the same pattern of bands, different from either normal C6 or C7 when separated by isoelectric focusing. An interesting speculation is that this may be the result of a 'Lepore' fusion of C6 and C7 genes.

At times the Workshop veered from the strict limits of complement genetics, Alper and F. S. Rosen (Children's Hospital, Boston) presented evidence that C3 nephritic factor is an IgG, on the basis of functional detection of clonal electrophoretic variants and on the transmission of such a clone across the placenta. A. Ferreira (New York University) described a new C4-binding protein in mice, the molecular association giving the appearance of *H-2* linkage. Since more than half of the known complement components now have genetic markers, new components are needed if healthy growth of the topic is to be maintained! ☐

Progress in coronaviruses

from David J. Garves

A symposium on Human and Animal Coronaviruses was held at the Agricultural Research Council Institute for Research on Animal Diseases, Compton UK on 24–25 March, 1977, and was organised by Professor A. P. Waterson, Royal Postgraduate Medical School, London, and Dr D. J. Garves, Compton.

THE Coronaviridae comprise a family of morphologically similar viruses that cause a wide variety of diseases in man and other animals. Following the recognition of coronaviruses as a distinct taxonomic group in 1968 (see *Nature* **220**, 650), with virus particles having a peripheral halo in negatively stained preparations, the number of viruses classified in the group and our knowledge of their characteristics has greatly increased. There are still large gaps in our understanding of the diagnosis, pathogenesis, structure and serology of this economically and, potentially, medically important group and attempts were made to fill these gaps at the symposium.

Recent reports of coronavirus-like particles in samples from human and equine enteritis, human nephropathy and feline infectious peritonitis have raised the problem of which criteria should be used to identify a coronavirus. It has been found that coronaviruses are difficult to establish in cell culture and for this reason morphology of the virus particle provides the major distinguishing feature. J. Almeida (Wellcome Research Laboratories) and R. Bingham (Royal (Dick) School of Veterinary Studies, Edinburgh) reported new evidence for the morphology and structure of the internal component of avian infectious bronchitis virus. They showed electron micrographs of virus particles within which flask-shaped structures could be seen, the mouth of the 'flask' appearing to open at the outer membrane of the virus. Whether these structures are present in other coronaviruses and what relation they have to the organisation of the genetic material has yet to be determined.

Recent studies on the polypeptide structures of human and animal coronaviruses have shown that, while the number and size of the structural proteins vary between members of the family, some similar features can be seen. The polypeptide profiles may provide a method to distinguish relationships within the coronaviruses and in this context the apparent similarity between the polyacrylamide gel patterns for avian infectious bronchitis virus (M. R. Macnaughton, Clinical Research Centre, London) and calf diarrhoea coronaviruses (J. Laporte, Thiverval-Grignon, France) was of interest.

The genome of avian and porcine coronaviruses has been shown to comprise single-stranded RNA but whether this has a messenger role, as in oncornaviruses and enteroviruses, or is a complementary strand, as in paramyxoviruses, has not been determined. Our understanding of the strategy of the coronavirus genome is greater, however, following the reports of Macnaughton and D. H. Pocock (ARC, Compton) that avian and porcine coronavirus RNA contains polyadenylic acid tracts. This evidence strongly suggests that the RNA has a messenger function and is yet another feature, together with virion morphology and the genome size, that coronaviruses have in common with the RNA tumour viruses. Bingham reported, however, that attempts to detect a reverse transcriptase in avian infectious bronchitis virus have proved unsuccessful, in line with the evidence from inhibitor studies suggesting that coronavirus replication does not proceed by way of DNA.

D. J. Alexander (Central Veterinary Laboratory, Weybridge) reported on the finding of long term infection of chickens with infectious bronchitis virus and these results, together with the evidence of chronic infection of mice with hepatitis virus and the carrier status of pigs with transmissible gastroenteritis, prompted K. McIntosh (University of Colorado, Denver) to suggest that future work on the human respiratory coronaviruses should consider implications of inapparent, chronic infections. It is possible that Balkan endemic nephropathy may result from such an infection, as K. Apostolov (Royal Postgraduate Medical School, London) reported a possible serological relationship between this disease and a human respiratory coronavirus.

Coronavirus serology is confused at the moment, with cross reactions being detected between human, bovine, murine and porcine viruses. The serological relationship between porcine transmissible gastroenteritis virus and a canine enteric virus is strong and D. J. Reynolds, (Compton) also presented evidence of antibodies to transmissible gastroenteritis in cats. It is possible that the agent in the cat responsible for the very high antibody levels may be associated with feline infectious peritonitis, a possible coronavirus whose morphology and physicochemical properties were presented by A. Osterhaus (Utrecht, Netherlands). The morphology of the purified particles was not characteristic of other coronaviruses and whether this was due to degradation or a different surface projection structure is not known. The agent of feline infectious peritonitis demonstrated the problem caused by the fact that coronavirus identification rests principally on the shape of the surface projection. It was generally agreed that other features including virus structure, the characteristics of the genome and the mode of replication within the cell needed to be determined before any virus could be assigned to the Coronaviridae, although this information is not known for some well accepted coronaviruses. Similarly, more data would be required before any meaningful subdivisions, such as separating the avian from the mammalian members, could be made within the Family.

In the field of coronavirus disease control there seemed to be doubtful correlation between antibody levels in serum and secretions and resistance to infection. It was recommended that more effort should go into investigating cellular and humoral aspects of immunity to diseases caused by coronaviruses. ☐

Accretion torques in X-ray pulsars

S. Rappaport & P. C. Joss

Department of Physics and Center for Space Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

The character of intrinsic pulse period changes in X-ray pulsars supports the now conventional model for these sources, wherein the X-ray luminosity is derived from the accretion of matter on to a rotating, magnetised compact object, probably a neutron star, and the pulse period changes are caused by its interaction with the accreting matter.

At least nine galactic X-ray sources are known to emit regularly pulsed X rays[1]. It is widely believed that the compact objects in these binary X-ray pulsar systems are rotating, magnetised neutron stars[2]. Black holes are eliminated as candidates for these objects because of the existence of periodic pulsations. One or more of the following arguments tend to rule against white dwarfs as the compact objects in at least seven of these systems: (1) the pulse period is too short to be a plausible surface rotation period of a white dwarf (see, e.g. ref. 3); (2) the observed X-ray luminosity is larger than the maximum luminosity of $\sim 10^{35-36}$ erg s^{-1} that has been predicted by some theoretical models of accreting white dwarfs[4,5]; or (3) the mass is probably above the Chandrasekhar limiting mass (see, for example, ref. 6).

Another means of distinguishing between white dwarf and neutron star models is through an analysis of the rates of change of the intrinsic pulse periods. As matter is accreted on to the compact star, torques are exerted that will tend to spin it up or down. The time required for accretion torques to spin up a white dwarf will, in general, be considerably longer than for a neutron star. We show here that the observed characteristic spin-up timescales for seven X-ray pulsars strongly support the view that in every source (1) the pulse period reflects the rotation period of a compact object (2), the accretion is mediated by a disk surrounding the compact object and rotating in the same sense, and (3) the compact object is a neutron star rather than a white dwarf.

Theory

In the accretion picture of pulsating X-ray sources, material from an overflow of the critical potential lobe of the companion or from a stellar wind is accreted toward the compact star in nearly Keplerian trajectories. If the net specific angular momentum of the accreting matter is too large to allow direct accretion on to the compact object, then matter will accumulate until an accretion disk forms and permits the outward transport of angular momentum through viscous forces. Ultimately, the matter reaches the Alfvén surface: the surface where the magnetic field of the compact object first dominates the particle dynamics, and where the matter will be forced to nearly co-rotate with the rotating compact star, provided that the circular Keplerian orbital velocity at the Alfvén surface exceeds the corotation velocity Ωr_A. Here, Ω is the magnitude of the vector angular velocity $\mathbf{\Omega}$ of the compact star and r_A is the characteristic radius of the Alfvén surface. An approximate relation[7,8] between the Alfvén radius and the parameters of the accreting matter and compact object is given by

$$r_A \approx 3\times10^{8}\,(\xi v_r/v_{ff})^{2/7}\left(\frac{\mu}{10^{30}\ \mathrm{G\ cm^3}}\right)^{4/7}\left(\frac{\mathscr{L}}{10^{37}\ \mathrm{erg\ s^{-1}}}\right)^{-2/7} \times\left(\frac{M}{M_\odot}\right)^{1/7}\left(\frac{R}{10^{6}\ \mathrm{cm}}\right)^{-2/7}\ \mathrm{cm} \qquad (1)$$

μ, M, R and $\mathscr{L}$ are the magnetic moment, mass, radius and luminosity of the X-ray star, respectively. The quantity ξ represents the fractional solid angle subtended at the compact star by the infalling matter at the Alfvén surface, and v_r/v_{ff} is the ratio of the average radial infall velocity of a particle to its free-fall velocity just outside the Alfvén surface.

In the accretion process, angular momentum is transferred to the X-ray star and its rotation period will change. The X-ray pulsations result from the rotation of the compact object, and the fractional rate of change of the pulse period, $P = 2\pi/\Omega$, can be expressed as[7,8]

$$\frac{\dot P}{P} = \frac{\dot M}{M}\left(\frac{M}{I}\frac{\mathrm{d}I}{\mathrm{d}M} - \frac{h_a}{h}\right) + \frac{\alpha}{I\Omega} \qquad (2)$$

I is the moment of inertia of the compact object, and h_a, h and α are the component of the specific angular momentum parallel to $\mathbf{\Omega}$ of the material crossing the Alfvén surface, the specific angular momentum of the X-ray star, and the external (viscous and magnetic) torques acting on the X-ray star just above the Alfvén surface, respectively. If the accreting matter counter-rotates with respect to $\mathbf{\Omega}$, then $h_a < 0$ and the second term in brackets in equation (2) tends to increase $\dot P/P$ (that is, tends to spin down the compact object). The first term in brackets is, in general, small compared to the second term for the case of a white dwarf or neutron star with $r_A \gg R$, provided that an accretion disk exists. The maximum spin-up or spin-down rate will occur when the external torques are small, which is expected if the circular Keplerian orbital velocity at r_A exceeds Ωr_A (ref. 9).

It is instructive to compare the maximum spin-up rate with those measured for the X-ray pulsars. The relation $\dot P/P \propto -(\dot M/M)(h_a/h)$ can be expressed[8] in terms of the parameters of the compact star and the luminosity:

$$\frac{\dot P}{P} \approx -2\times10^{-5}\left(\frac{M}{M_\odot}\right)^{-3/2}\left(\frac{R}{10^{6}\ \mathrm{cm}}\right)\left(\frac{R_g}{10^{6}\ \mathrm{cm}}\right)^{-2} \times\left(\frac{r_A}{10^{8}\ \mathrm{cm}}\right)^{1/2}\left(\frac{\mathscr{L}}{10^{37}\ \mathrm{erg\ s^{-1}}}\right)\left(\frac{P}{1\ \mathrm{s}}\right)\ \mathrm{yr^{-1}} \qquad (3)$$

where R_g is the radius of gyration of the X-ray star. When combined with (1), the relation becomes

$$\frac{\dot P}{P} \approx -3\times10^{-5}\,(\xi v_r/v_A)^{1/7}\left(\frac{M}{M_\odot}\right)^{-10/7}\left(\frac{R}{10^{6}\ \mathrm{cm}}\right)^{6/7}$$

$$\left(\frac{R_g}{10^6\ \mathrm{cm}}\right)^{-2}\left(\frac{\mu}{10^{30}\ \mathrm{G\ cm^3}}\right)^{2/7}\left(\frac{\mathscr{L}}{10^{37}\ \mathrm{erg\ s^{-1}}}\right)^{6/7}\left(\frac{P}{1\ \mathrm{s}}\right)\ \mathrm{yr^{-1}} \tag{4}$$

For simplicity, we write this as

$$\frac{\dot{P}}{P} \approx -3\times10^{-5} f\left(\frac{P}{1\ \mathrm{s}}\right)\left(\frac{\mathscr{L}}{10^{37}\ \mathrm{erg\ s^{-1}}}\right)^{6/7}\ \mathrm{yr^{-1}} \tag{5}$$

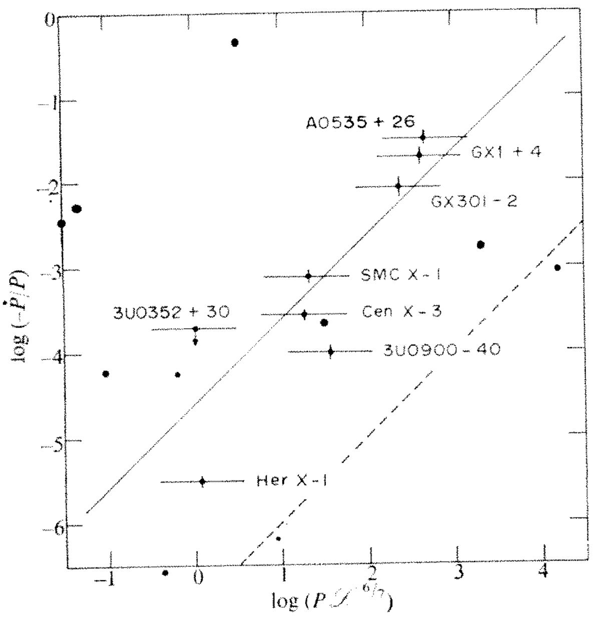
where the dimensionless function, *f*, is expected to be of order unity for a neutron star and contains parameters that are not yet measurable for most or all of the X-ray pulsar systems.

Observational information

The empirical relation between $\dot{P}/P$ and $(P\mathscr{L}^{6/7})$ is plotted in Fig. 1. The luminosities, pulse periods and spin-up rates for eight X-ray pulsars were taken from the sources indicated in the following paragraphs. In each case, the uncertainty in the distance to the source, the possibility of anisotropic beaming of the X-ray flux, and substantial source variability all contribute to the uncertainty in the luminosity determination. We have assigned to each source luminosity a reasonable but arbitrary uncertainty of a factor of three. For four of the sources (3U0352+30, GX301-2, GX1+4, and A0535+26), the identification of the optical counterpart is probable but not certain; if any of these identifications proves to be erroneous, the corresponding distance estimate would, of course, be invalid.

The pulse period for **Hercules X-1** observed with the SAS-3 satellite in 1975 July was 1.2378082±0.0000001 s (ref. 10). This period determination, coupled with Uhuru measurements[11] covering the interval 1971 December–1973 March, yield $\dot{P}/P = (-3\pm0.5)\times10^{-6}\ \mathrm{yr^{-1}}$. Over shorter time intervals, the value of $\dot{P}/P$ fluctuates and its sign even reverses[11]. These sporadic intervals of spin-down, together with the small average value of $|\dot{P}/P|$, are indicative of a near balance between spinup and spindown for this source[9]. Hence, external torques are probably important in this system. The theoretical interpretation of the short-term fluctuations in $\dot{P}/P$ has been discussed previously[12]. The luminosity of Her X-1, taken from ref. 13 (where the distance is estimated to be in the range 2–6 kpc), is $\sim 1\times10^{37}\ \mathrm{erg\ s^{-1}}$. We assume here that a nearly constant X-ray luminosity persists throughout the 35-d cycle of the source (see, e.g., refs 13, 14).

Fig. 1 The empirical relation between the fractional rate of change of the pulse period and the parameter (pulse period × luminosity$^{6/7}$) for eight binary X-ray pulsars. The units of $\dot{P}/P$, P and $\mathscr{L}$ are yr^{-1}, s and 10^{37} erg s^{-1}, respectively. The solid line is the best fit to a power law with logarithmic slope 1.0. The data point for Her X-1 and the upper limit for 3U0352+30 were excluded from the fit. In all cases, we have assumed that the proposed optical identifications are correct (see text). The good agreement with equation (5) for $f \simeq 1$ (see text) lends credence to the presently conventional model of X-ray pulsars as rotating, magnetised, neutron stars that are undergoing accretion. The dashed line is the expected relation for ~1 $M_\odot$ white dwarfs (see text).



The pulse period for **3U0900-40** was measured with SAS-3 in 1975 June–July to be $P = 282.8916\pm0.0002$ s (ref. 6). Ten months later the pulse period measured with SAS-3 was $P = 282.870\pm0.004$ s. This yields an average value of $\dot{P}/P = (-1.0\pm0.3)\times10^{-4}\ \mathrm{yr^{-1}}$. The details of the latter SAS-3 observation will be presented elsewhere. Because only two data points were used to determine $\dot{P}/P$, we cannot estimate the magnitude of short-term fluctuations in this quantity (compare with the discussions of Her X-1 and Cen X-3), and we therefore assign a somewhat larger uncertainty to $\dot{P}/P$ than its formal error. We adopt a value of $\sim 1\times10^{36}\ \mathrm{erg\ s^{-1}}$ for the average luminosity of 3U0900-40 (ref. 15).

Ariel V measurements[16] of the **Centaurus X-3** pulse period in 1975 January (4.83704±0.00004 s) can be combined with Uhuru data[17] covering 1971 January–1972 December, to yield $\dot{P}/P = (-2.8\pm0.4)\times10^{-4}\ \mathrm{yr^{-1}}$. The luminosity is taken to be $\sim 5\times10^{37}\ \mathrm{erg\ s^{-1}}$ (ref. 18). Cen X-3 is also observed to undergo brief intervals of spin-down on shorter timescales[17].

The pulse period of **3U0352+30** ($P = 835.6$ s) has been measured on at least six separate occasions during a 4-yr interval with the Copernicus[19] and SAS-3 (unpublished SAS-3 data, J. G. Jernigan) satellites, and has remained constant to about 1 part in 1.5×10^3. It is possible that a somewhat larger secular change in the intrinsic pulse period has been fortuitously cancelled during these observations by orbital motion, but we regard this as highly unlikely. A luminosity of $\sim 4\times10^{33}\ \mathrm{erg\ s^{-1}}$ is derived from the inferred distance of ~ 350 pc (ref. 20).

The **SMC X-1** pulse period observed[21] with the SAS-3 satellite in 1976 February was 0.714890±0.000004 s. This represents a change of 0.0026 s from the pulse period determined from a reanalysis[22] of Uhuru data from 1971 June ($P = 0.71748\pm0.00026$ s). Hence, $\dot{P}/P = (-7.7\pm2.0)\times10^{-4}\ \mathrm{yr^{-1}}$, where we again adopt a more conservative uncertainty because only two data points were used in the determination. The average luminosity of SMC X-1 (ref. 21) is taken to be $\sim 5\times10^{38}\ \mathrm{erg\ s^{-1}}$.

The X-ray pulsations from **GX301-2** have been studied on five separate occasions by the Ariel V, SAS-3, and OSO-8 satellites during 1975 January–1976 February. In 1975 January the pulse period was 699.3±0.5 s (ref. 23). During the interval 1975 July 18–25 the pulse period ranged from 699.9 to 700.5 (± ~0.2) s (ref. 24). By 1975 December the pulse period had decreased to 696.4±0.4 s (refs 23, 25) and it was observed to be nearly the same in 1976 January[24]. Thus, the pulse period remained the same to within ~1 s for ~0.5 yr after its discovery, after which it decreased by ~4 s during the next ~0.5 yr. To explain this change in pulse period by orbital Doppler shifts, a minimum projected orbital velocity of $v_x \sin i \sim 800\ \mathrm{km\ s^{-1}}$ is required. This source has been identified with the Be star Wray 977 (refs 26, 27); the suggested orbital period is ~ 20 d (ref. 28) which, if verified, would yield a mass function of $f(M) \gtrsim 10^3\ M_\odot$ for $v_x \sin i \gtrsim 800\ \mathrm{km\ s^{-1}}$. Hence, it is highly probable that the observed long-term period changes are mainly intrinsic rather than orbital. We conclude that $\dot{P}/P = (-0.8\pm0.3)\times10^{-2}\ \mathrm{yr^{-1}}$. The luminosity is $\sim 3\times10^{36}\ \mathrm{erg\ s^{-1}}$ for a source distance of ~ 2 kpc (ref. 26).

The periodic nature of the X-ray emission from **GX1+4** was discovered in 1970 October during an MIT balloon observation[29]. The pulse period at that time was 135±4 s (W. H. G. Lewin, personal communication). The pulse period was subsequently measured with the Copernicus satellite[23] in 1972

September (P = 130±0.4 s, aliased by the sampling time of the instrument[23]), and with the SAS-3 satellite[30] in 1975 December (P = 121.370±0.005 s). The pulse period was also measured with the OSO-8 satellite[31] on two occasions: 1975 September (P = 122.46±0.03 s) and 1976 March ($P \sim 120.0$ s). These data yield an average value of $\dot{P}/P = (-2.0\pm0.5)\times10^{-2}$ yr^{-1}. The luminosity of this source is estimated[32] to be $\sim 4\times10^{37}$ erg s^{-1}, based on the tentative identification of an M giant star[33] at ~ 10 kpc as the optical companion (and on its probable proximity, in any event, to the galactic centre).

When pulsations were first discovered[34] from the transient source **A0535+26** on 1975 April 28, the pulse period was 104.17±0.09 s (G. K. Skinner, personal communication). The period was determined about 1 month later to be 103.828 s (ref. 35). We attribute this substantial difference to a change in the intrinsic pulse period. If this is the case, then $\dot{P}/P = (-3.5\pm0.9)\times10^{-2}$ yr^{-1} during 1975 May. Subsequent smaller changes in the pulse period have been attributed largely to orbital motion[36]. The source has been tentatively identified with the Bpe star HDE 245770 (ref. 37). If we take the distance of this source to be in the range ~ 1.5 kpc (J. Hutchings, personal communication) to ~ 5 kpc (ref. 37), then the average luminosity during 1976 May was $\sim 6\times10^{37}$ erg s^{-1}.

The quantities $\dot{P}/P$ and $P\mathscr{L}^{6/7}$ for the above sources are displayed in Fig. 1. Spin-up is observed in all cases (that is, the average value of $\dot{P}/P$ is negative), indicating that the accreting matter generally rotates in the same sense as the compact object (see equation (2)). A log–log plot of relation (5) has slope 1.0 and an intercept at $\log(-\dot{P}/P) = -4.5+\log f$. Superimposed on the data points in Fig. 1 is a best-fit straight line with slope 1.0. The data for Her X-1 were excluded in the fit because of the apparent balance between spin-up and spin-down and the resultant possibility that appreciable external torques are present in this source. In view of the probable fluctuations in f from source to source, the fit is quite good. This result strongly indicates that the second term in parentheses in equation (2) dominates the first term, and that accretion disks are therefore present in these sources. In at last two theoretical studies[38,39], the existence of an accretion disk in some binary X-ray sources had been called into question.

The measured intercept of the straight line on Fig. 1 is -4.6 ± 0.4 (2σ), in good agreement with equation (5) for $f \simeq 1$. Thus, the observationally determined average value of f is $0.3 \lesssim f_{\rm obs} \lesssim 2$.

Discussion and conclusions

For the case where the X-ray star is a rotating white dwarf, the value of f is much smaller than for a neutron star. The radius and radius of gyration of a white dwarf are $\sim 10^9$ cm, while the magnetic moment is

$$\mu = 1\times10^{33}\left(\frac{B}{10^6\ \mathrm{G}}\right)\left(\frac{R}{10^9\ \mathrm{cm}}\right)^3\ \mathrm{G\ cm^3},$$

where B is the surface magnetic field and R is the white dwarf radius. Therefore, we estimate from equation (4) that for a white dwarf $f \sim 0.003$, which is well outside the observationally determined range.

It has been suggested[40] that the short-period ($P < 10$ s) X-ray pulsars may be white dwarfs that are undergoing accretion and are vibrating in a nonradial mode that is excited by the nuclear burning of the accreted matter. In this model, the pulse period is equal to the vibration period of the white dwarf. The model cannot account for the long-period pulsars ($P > 100$ s), however, since the vibration period of a white dwarf cannot be sufficiently long unless its mass were implausibly small ($\lesssim 0.1\ M_\odot$). Thus, if the short-period pulsars are actually white dwarfs, then the strong correlation between $\dot{P}/P$ and $P\mathscr{L}^{6/7}$ on Fig. 1 must be fortuitous.

The experimentally determined range of values for f is consistent with the estimated values of neutron star parameters (that is, $M \sim 1M_\odot$, $R_g \sim R \sim 10^6$ cm, and surface magnetic field $B = \mu/R^3 \sim 10^{12}$ G). Because these parameters appear in the function f with widely varying exponents (see equation (4)), the constraints that one can place on the parameters differ greatly. The magnetic field can range from $\sim10^{11}$ to $\sim10^{13}$ G and the parameter $(\xi v_r/v_{\rm ff})$ can range over ~4 orders of magnitude without significantly affecting our determination of f. The mass and radius, however, should lie within a factor of ~2 of the nominal values for neutron stars suggested above.

The best-fit straight line in Fig. 1 can be used to predict the relationship among pulse period, spinup or spindown rate, and luminosity of any additional X-ray pulsars. For example, if a new X-ray pulsar is discovered and $\dot{P}/P$ is measured, the intrinsic X-ray luminosity of the source can be estimated (unless there are other complications, as in the case of Her X-1) and its distance may then be inferred to within a factor of ~2. Conversely, if the pulse period and X-ray luminosity are known, $|\dot{P}/P|$ may be estimated. We note in this regard that if the existence of 32-min X-ray pulsations in GX17+2 (ref. 19) is confirmed, and if this period represents the rotation period of a neutron star, then $|\dot{P}/P|$ should be ~ 0.7 yr^{-1}. Thus, at the present time the pulse period of GX17+2 should be about one-half its previously reported value, but the spin-up or spin-down timescale of this source would then be considerably shorter than its known lifetime ($\gtrsim 10$ yr). This result tends to rule against a rotational origin for the pulsations in this source. Similarly, if the 4.8 h period in Cyg X-3 is interpreted[41] as the rotation period of a neutron star, then $|\dot{P}/P|$ should be ~ 2 y^{-1}. The measured limit for $|\dot{P}/P|$ in Cyg X-3 is $\lesssim 10^{-5}$ yr^{-1} (ref. 42). Thus, it seems very likely that the 4.8-h periodicity is orbital rather than rotational in origin[42].

Formation of intense magnetic fields near the surface of the Sun

Convection concentrates magnetic flux into ropes between granules in the solar photosphere, with average fields of up to 1500 G. The magnetic energy density is locally much greater than the kinetic energy density. Theoretical limits to the amplification of magnetic fields by convection are analysed and related to the observations.

HIGH resolution, ground based observations have recently revealed the presence of very strong, small scale magnetic fields in the solar photosphere[1,2]. More than 90% of the total magnetic flux, outside pores and sunspots, that emerges from the sun is confined to ropes that are only a few hundred kilometres across[1], with typical fluxes estimated to be less than 5×10^9 Wb (ref. 3). Estimates of the field strength vary from 1,000 to 2,000 G: the only direct measurement of Zeeman splitting, in an infrared line, indicates a field between 1,200 and 1,700 G (ref. 2). These magnetic features are closely associated with the cellular convection pattern seen as photospheric granulation. They can be studied indirectly by observing the solar filigree[4] and small scale photospheric faculae[3]. The filigree is composed of bright points and elongated crinkles, which lie in the dark lanes between granules and are moved about by granular convection; moreover, the lifetime of individual features (about 10 min) is similar to the typical lifetime of a granule[4].

In a highly conducting plasma, magnetic flux is inevitably swept aside by horizontal motions, and concentrated into vertical ropes at the edges of convective cells, especially at the corners where several cells meet. The kinematic amplification of weak magnetic fields is limited by ohmic diffusion but stronger fields exert forces which impede the concentration[5-8]. There is, however, no adequate theory to describe the dynamic interaction between magnetic fields and convection in the Sun. Traditionally it has been supposed that flux concentration is halted when equipartition between the local magnetic energy density and the kinetic energy density has been achieved. So the field strength B should be limited by the equipartition field $B_e = (\mu\rho U^2)^{1/2}$, where ρ is the density and U the local maximum speed of convection. In the sun B_e rises from about 200 G at the photosphere to 600 G at 1,000 km depth. Hence the equipartition limit is exceeded by the observed magnetic fields.

There is an obvious upper bound to the average field strength within a flux rope, for the field is contained by the external pressure[9]. Clearly the field at the boundary cannot exceed the value $B_p = (2\,\mu p)^{1/2}$ that balances the external pressure p when there is no gas pressure within the rope. The field may be stronger on the axis of the tube but in a small flux rope the field is nearly vertical and so the average field strength B cannot appreciably exceed B_p. (If B increases with depth the field observed at the centre of the tube may be larger, owing to the greater transparency associated with the Wilson depression.) At the photosphere $B_p \approx 1{,}600$ G and B apparently attains this value. But B_p increases rapidly with depth in the convective zone: at 1,000 km depth $B_p \approx 10^4$ G, at 10,000 km $B_p \approx 4 \times 10^5$ G and at 100,000 km $B_p \approx 10^7$ G.

Thus the small scale magnetic fields pose several theoretical problems. How are they formed and maintained? What limits the field strength? And, in particular, can the field reach values of 10^7 G at the base of the Sun's convective zone?

There are two distinct mechanisms for amplifying the field. The first relies on inhibition of convection by the magnetic field, and the consequent cooling of photospheric gas until thermal and dynamical equilibrium is achieved[10,11]. In the second, flux is concentrated by the motion until the Lorentz force is strong enough to halt the amplification of the field. Both processes must be included in a full treatment of the dynamic interaction between magnetic fields and convection. We shall show that the equipartition limit is irrelevant and that the maximum field strength that can be produced by flux concentration in the Sun is typically an order of magnitude higher than B_e. Near the photosphere, the field is limited by B_p and cooling is important. Deeper down, the magnetic pressure remains small compared with the gas pressure, though fields of the order 10^4 G can be maintained.

The equipartition limit

The principal argument advanced to support the equipartition limit is that flux concentration can only proceed while the magnetic pressure is less than the dynamic pressure of the motion. If the density and temperature within the flux rope are equal to their mean values in the convecting layer outside it then the magnetic pressure must be contained by an excess gas pressure around the flux tube, and fluctuations in the external pressure should be comparable with $\frac{1}{2}\rho U^2$. Hence $B < B_e$. This argument fails, however, if gas can flow downwards along the lines of force, evacuating the flux tube and reducing the internal pressure. Owing to the rapid increase of density with depth in the Sun, the displaced material can easily be accommodated and so the only limit is set by B_p.

Observations show a downward flow associated with small scale magnetic fields. In the photosphere the greatest measured velocity is 2 km s^{-1} and apparently the velocity *decreases* with height (ref. 2). The equipartition argument can be adapted for this flow; Parker[12] has investigated various models with fields that are locally enhanced by motion along the lines of force but they are never increased by more than the equipartition field, which is only 400 G. Moreover, for steady flow along a flux tube the downward velocity should increase with height, contrary to the observations. It seems likely that the downflow is a transient effect, associated with the evacuation of the flux tube as it is formed, rather than a permanent feature of an equilibrium configuration.

The thermal mechanism

Biermann's[10] explanation of sunspots invokes the inhibition of convection by a strong magnetic field. Concentration of magnetic flux reduces the convective energy transport and the photospheric temperature falls since there is less energy to radiate. Cooling proceeds, and the superadiabatic gradient increases, until there is a balance between the reduced energy flux and emission from the photosphere, as well as dynamic equilibrium within the sunspot. This final equilibrium is locally stable[13].

This mechanism suggests that a weak uniform field might be thermally unstable: slight condensations would have lower temperatures and pressures, and therefore be liable to further collapse. A field free gas, however, is not liable to sudden condensations. The gas will remain stable unless the magnetic field exceeds some critical value and its effect on convective transport has become significant. The measured magnetic flux through the solar photosphere corresponds to an average field that is too small to produce this instability. The configuration is metastable and the field must be concentrated to rather greater strengths (for example, by supergranular convection) before any thermal instability can proceed.

There is another stabilising effect. The temperature rises beneath any obstacle that blocks the heat flux: hence a local condensation that increases the magnetic field sufficiently to impede convection tends to enhance the thermal as well as the magnetic pressure[9]. At the level where heat flux is diverted convection must produce additional pressures sufficient to contain any resulting increase of the total pressure in the flux concentration. Since the kinetic energy increases with depth, so that B_e reaches about 10^4 G at the base of the convective zone, it is quite possible to form fields of several thousand gauss in flux ropes that extend deep into the Sun.

These arguments apply to the formation of sunspots, which are large compared with the scale of granular convection. For flux ropes that are small compared with granules, the thermal mechanism cannot consistently be separated from the effect of the convective motion. Slender flux tubes are heated laterally[14], with a consequent reduction in the temperature deficit, and it is unlikely that the thermal instability will grow faster than the rate at which flux is swept across the cell. At greater depths, where the flux rope is approximately in thermal equilibrium with its surroundings, the thermal mechanism cannot function.

The normal photospheric temperature of the Sun is about 6,000 K and a small flux tube may be about 500 K cooler than its surroundings[14]. If the magnetic pressure nearly balances the external pressure then the flux tube must be almost completely evacuated. Below the surface, lateral heating is less important and the temperature difference can increase. Ropes are formed as flux is brought together by granular convection[4,13], giving fields of order B_e, which cause a slight reduction of convective transport in the ropes. The resultant cooling marginally decreases the internal gas pressure. On the axis of a tube, gas is no longer supported by the pressure gradient and therefore falls. The density drops and the tube is squeezed by the external pressure until some equilibrium is reached. A proper description of this process requires a theory of energy transport in the flux tube. We shall instead assume that the density and temperature within the tube adjust themselves to maintain a pressure balance and seek limits to the fields that can be supported by external convection.

Flux concentration by convection

Busse[15] pointed out that laminar convection is dominated by diffusive effects and that the extent to which fields are amplified depends on the relative rates of ohmic, viscous and thermal dissipation. In a Boussinesq fluid (such as a liquid or a shallow layer of gas) the pressure does not enter the equation of state and can be eliminated from the mathematical description of the problem. The equipartition argument, which depends on balancing different contributions to the total pressure, is therefore irrelevant. The governing equations are nonlinear and must be solved on a computer[16]. Several simple configurations have been studied systematically in a series of numerical experiments. In these computations two-dimensional[17,18] or axisymmetric[19] solutions were obtained for convection between free boundaries in a fluid of electrical conductivity σ and kinematic viscosity ν, in the presence of an imposed vertical magnetic field of average strength B_0. The general behaviour of these results, which is similar for each configuration, is summarised in Fig. 1.

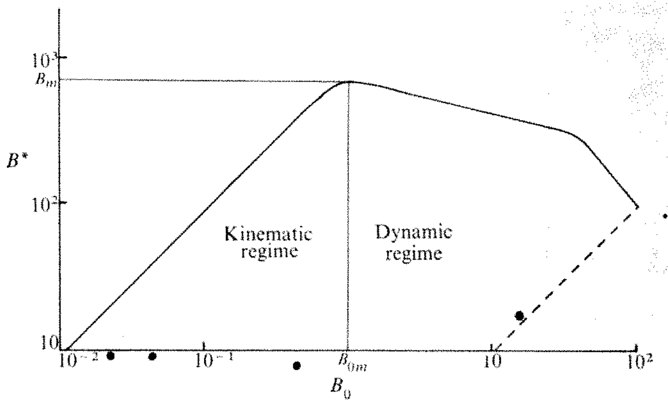

Fig. 1 Amplification of the magnetic field by axisymmetric convection: logarithmic plot of the peak field B^* as a function of the average field B_0. Magnetic fields are measured in terms of the field B_{0m} at which B^* reaches its maximum value B_m. On the broken line $B^* = B_0$. For this particular run $\nu/\eta = 10$, $B_m/B_{0m} \approx 900$ and the magnetic field suppresses convection for $B_0/B_{0m} \geqslant 100$.

When the imposed field B_0 is weak the magnetic forces cannot affect the motion. In a steady state the field is amplified kinematically[6] and the peak field B^* is proportional to B_0. As B_0 is increased, the Lorentz force becomes significant and the convective velocity is reduced. The amplified field B^* reaches a maximum, B_m, when its dynamical effect is important. In this regime the field is confined to ropes, either at the centre or at the edge of the convective cell, and convection is almost entirely excluded from these ropes. An axisymmetric example is shown in Fig. 2: the flux is concentrated at the centre of the cell, which is stagnant, and the convective eddy occupies a toroidal region that encloses the flux rope. This dynamic regime can be successfully analysed and quantitatively understood in terms of a simple physical model[19]. For higher values of B_0 the amplification drops, at first gradually and then more rapidly, and B^* decreases until convection is completely suppressed, whereafter $B^* = B_0$.

In the kinematic regime the work done in containing the magnetic field is small, and the motion is limited by viscous friction. Obviously, kinematic amplification cannot continue after ohmic dissipation has become important. In all the model calculations the transition from the kinematic to the dynamic regime occurs when, or shortly before, the rate of ohmic dissipation in the flux tube becomes comparable with the rate of viscous dissipation in the convecting region. The maximum field B_m can therefore be estimated by equating these two dissipation rates. For higher values of B_0, well into the dynamic regime, viscous losses are relatively small and the rate of working by the buoyancy force is balanced by work done in keeping the magnetic field within the flux rope. With suitably chosen parameters the field $B^* > B_e$, though global equipartition (between the total magnetic and kinetic energies) occurs only at a value of B_0 greater than that corresponding to B_m.

In three-dimensional flow, flux ropes are formed either at the centre of a cell (as illustrated in Fig. 2) or at a corner where several cells meet. The maximum magnetic field can be estimated from a very simple argument. Consider a cell of depth d and similar horizontal dimensions, and suppose that the flux rope has a radius $\delta \ll d$. The ohmic dissipation per unit volume in the

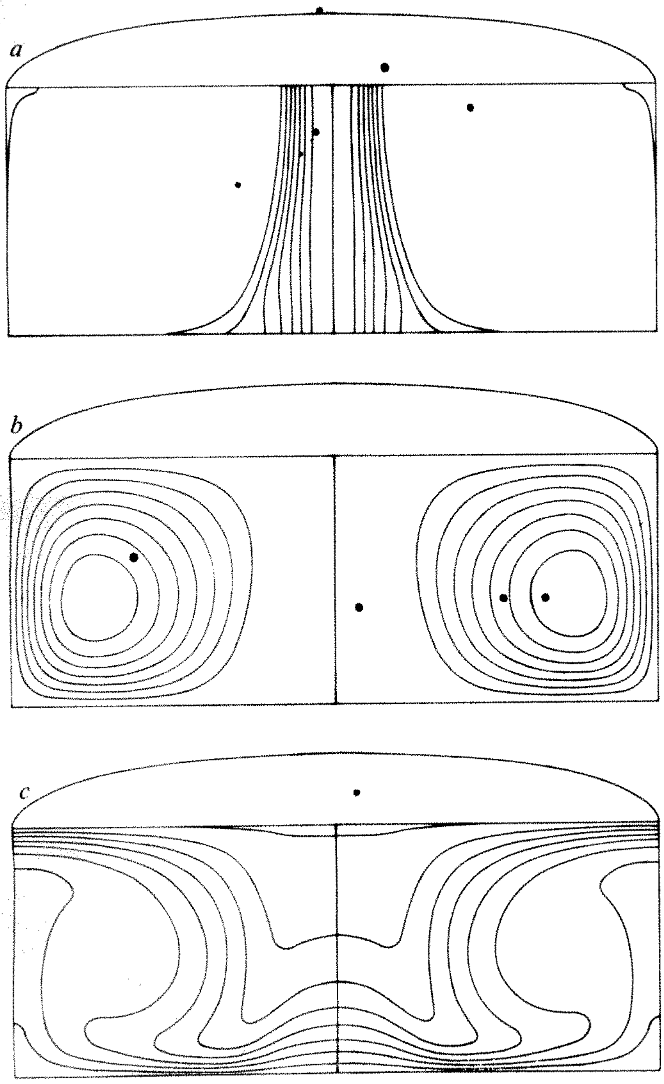

Fig. 2 Thermal convection in a magnetic field: formation of a flux rope in the dynamic regime. Steady solution for axisymmetric flow in a cylindrical cell with free boundaries. *a*, Lines of force of the magnetic field (equally spaced contours of the Stokes flux function); *b*, streamlines (contours of the Stokes stream function); *c*, isotherms, in a meridional plane. The flow is upward around the periphery of the cell and flux is concentrated into an almost stagnant region near the axis.

flux rope is j^2/σ, where j is the current density, and the total ohmic dissipation rate is

$$\left(\frac{j^2}{\sigma}\right)\delta^2 d \sim \left(\frac{B^{*2}}{\mu^2\delta^2\sigma}\right)\delta^2 d = \eta\frac{B^{*2}d}{\mu},$$

where the magnetic diffusivity $\eta = (\mu\sigma)^{-1}$. This expression is independent of δ. The total viscous dissipation rate is $(\rho\nu U^2/d^2)d^3 = \rho\nu U^2 d$. The maximum field B_m is reached when these are approximately equal, so that

$$\frac{B^2{}_m}{B_e{}^2} = \frac{B^2{}_m}{\mu\rho U^2} \sim \left(\frac{\nu}{\eta}\right).$$

This ratio becomes arbitrarily large for appropriately chosen diffusivities. The maximum field B_m is only attained for a particular value, B_{0m}, of B_0. In the kinematic regime, the ratio B^*/B_0 is proportional to the magnetic Reynolds number Ud/η. Hence the transition to a dynamic regime occurs when

$$B_0 \sim B_{0m} \sim \frac{(\eta\nu)^{\frac{1}{2}}}{Ud}B_e.$$

Amplification of magnetic fields in the solar convective zone

In the Sun, convection is not laminar and the pressure cannot be eliminated from the governing equations. Nevertheless, we assume that the field strength cannot exceed the value for which the power needed to contain the flux rope is equal to the rate of turbulent energy dissipation. Observations of granules and supergranules suggest that convective eddies lose their identity after a lifetime τ comparable with the turnover time d/U, as implied by the mixing length theory of convection. Thus the energy dissipation rate in a cell is approximately $\frac{1}{2}\rho U^2 d^3/\tau \sim \rho U^3 d^2$. Although large scale motion is excluded from the flux rope, inefficient small scale convection is still possible within it. The motion is time dependent and mainly vertical, so the field spreads out with an effective diffusivity $\tilde{\eta}$ that is much smaller than Ud (ref. 20). Applying the same argument as before, we find that

$$\frac{B^2}{B^2{}_e} \sim \frac{d^2}{\tilde{\eta}\,\tau} \sim \frac{Ud}{\tilde{\eta}}.$$

Thus the ratio of B_m to the equipartition field B_e varies as the square root of the magnetic Reynolds number. (This would follow directly from the previous result if ν were replaced by an eddy diffusivity of order Ud.) The maximum field $B_m \sim (\mu\rho U^3 d/\tilde{\eta})^{\frac{1}{2}}$ then occurs when the average field through the cell is $B_{0m} \sim (\tilde{\eta}/Ud)^{\frac{1}{2}} B_e$.

To find upper bounds for the field concentrated between granules or supergranules we need estimates of the diffusivity $\tilde{\eta}$. Microturbulent velocities in sunspots have magnitudes of about 1 km s^{-1} and horizontal scales of about 10 km (ref. 21): adopting similar values for small scale convective motion in flux ropes between granules, we have $\tilde{\eta} \sim 10^7$ m^2 s^{-1}. Taking typical values for the granular velocity field ($U = 1$ km s^{-1}, $d = 10^3$ km, $\rho = 10^{-3}$ kg m^{-3}, $\tau = 500$ s) we then find that $B_e \sim 350$ G, while $B_m/B_e \sim 15$; hence $B_m \sim 5{,}000$ G and is greater than B_p. In practice, therefore, the limit is set by the pressure balancing field B_p, which can be reached by purely kinematic amplification, without the magnetic forces having a significant effect on convection. Now B^* will not reach 1,600 G if B_0 is less than about 16 G. Hence strong fields should be present only for fluxes $B_0 d^2 \gtrsim 10^9$ Wb, which is consistent with Mehltretter's[3] estimate of the flux in small scale features.

Magnetic fields are also concentrated at the boundaries of supergranules, which correspond to larger scale and more deepseated convection ($U = 0.4$ km s^{-1}, $d = 1.5\times10^4$ km, $\rho = 10^{-2}$ kg m^{-3}, $\tau = 40$ h). An estimate of the magnetic diffusivity derived from the decay of longlived sunspots gives $\tilde{\eta} \approx 2\times10^7$ m^2 s^{-1} (ref. 20). Hence $B_m/B_e \sim 9$ and, since $B_e \sim 1500$ G, $B_m \sim 12{,}000$ G. This crude upper bound is greater than any field that has been observed on the sun but much less than the pressure-balancing field in the same region. The corresponding flux, $B_{0m}d^2 \sim 10^{12}$ Wb, is comparable to that in a small sunspot.

Deep down in the convective zone the scale of motion is likely to be around 10^5 km. A crude estimate of B_m yields a value of about 70,000 G, corresponding to a flux of about 10^{15} Wb. If the available flux is no more than, say, 10^{14} Wb (the flux through a large sunspot or an active region) then the magnetic field is kinematically amplified to a value around 10,000 G.

We do not suggest that these estimates are precise. But we have shown that fields greater than the equipartition value can be formed where flux is concentrated by the horizontal flow. In the Sun, the convective velocity is outwards from the centres of granules and supergranules and, in a compressible layer, the horizontal velocity is reversed only near the bottom of a convection cell[22]. Hence concentration is predominantly at the cell boundaries. Some field lines are also carried around within the cells but observations of inner network fields[2] suggest that the flux involved is relatively small.

Near the photosphere an initially weak field will be concentrated by convection until the thermal instability takes over. The field is limited by the need to maintain pressure balance, and cannot appreciably exceed 1,600 G in a small flux rope. At depths greater than about 1,000 km thermal effects are less important, cooling is slight and flux concentration is limited by diffusion. The maximum field B_m may be an order of magnitude greater than the equipartition field and we expect that flux ropes may have fields of up to about 10^4 G. Similar arguments may be applied to estimate the fields in other stars where magnetic flux is concentrated by convection.

We thank D. R. Moore for advice and assistance in computation, and T. G. Cowling, W. V. R. Malkus, E. N. Parker, H. U. Schmidt and E. A. Spiegel for helpful comments. D. J. Discovery of the Hadrynian Polar Track and further study of the Grenville problem

W. A. Morris & J. L. Roy

Geomagnetic Laboratory, Earth Physics Branch, Energy, Mines and Resources, Ottawa, Ontario, K1A 0E4 Canada.

Palaeomagnetic poles from North America for the period 1,150–650 Myr fall on a simple single great circle polar track—the Hadrynian Track, and the Grenville Loop. This Loop is consistent with Laurentia and Grenvillia having been an integral single plate unit from the onset of remanence blocking (metamorphic cooling) in the Grenville Province.

PALAEOMAGNETIC studies from the Grenville Province have yielded palaeomagnetic poles that apparently differ from those observed from Interior Laurentia. The many models proposed to explain this discrepancy fall into two classes: the two-plate model [1–6], and the one-plate model[4,5,7–10]. On the two-plate model, it is considered that the north-trending Grenville Track records the gradual convergence of a separate Grenville plate towards Laurentia. Difficulties with the two-plate model are: (1) the magnetisations which are all post-orogenic were reset at the maximum separation of the two regions, the collision itself apparently produced barely any detectable reheating, (2) the lack of evidence of a suture zone, and (3) the presence of pre-orogenic geological units which cross the Grenville Front and can be recognised as far as 100 km into the Grenville Province. On the one-plate model, the Grenville Track is incorporated into the North American polar wander path by means of a so-called Grenville Loop. The difficulty of this model is in establishing the sense and time calibration of this Loop. Both counter-clockwise[10] and clockwise[4,5,7–9] loops have been proposed. Establishing the age sequence of the Grenville Track is clearly of major importance. In comparison with the radiometric evidence, the ages assigned to Grenville Loops seem to be either too old[7,8] (1,400–1,250 Myr), or too young[4,5,9] (800–600 Myr). In addition, some of the reported Grenville poles which do not fall on the so-called Grenville Track (Fig. 2) have not been satisfactorily accommodated by any of the proposed one- or two-plate models.

We present here a polar wander path for the period 1150–670 Myr (Figs 1–3) which uses all the presently available North American palaeomagnetic data. A portion of the path forms a Grenville Loop which incorporates all of the Grenville poles (including a north-trending Grenville Track). It also contains some non-Grenville poles. The age assignment for this loop (1,050–950 Myr) is consistent with radiometric evidence. The latter portion of the polar path (950–670 Myr) follows an almost great circle path (Figs 2 and 3) from close to the Equator at 180°E, over the present geographic North Pole, and down to the Equator again close to 0°E. During all portions of this path the average drift rate relative to the pole is 8 cm yr^{-1}, a much more conservative figure than the drift rates required by the previously proposed one-plate models.

Data interpretation criteria

For the construction of this path some initial interpretations are questioned, and new interpretations are presented. In our opinion it is difficult in any study of igneous, metamorphic or sedimentary rocks to show indisputable evidence of an initial (primary) magnetisation. Only a positive contact test provides evidence of a single simple thermo-remanent magnetisation (TRM). In all other cases, elucidation of the sequence of remanence acquisition can only possibly be achieved by detailed laboratory experimentation. For igneous and metamorphic rocks extensive alternating field (a.f.) and thermal remanence cleaning is obligatory; a.f. cleaning alone is inadequate to identify the remanence carrier (for example, magnetite or haematite). Thermal experiments provide the respective blocking temperature spectra, and it may then be possible, using vector analysis, to establish the magnetisation sequence. This still remains hazardous unless it can be shown that both haematite and magnetite remanences are the result of a single cooling event (TRM). Chemical remanence (CRM) acquisition at low or intermediate temperatures, which is probably commonplace, can quite easily produce haematite remanence with high blocking temperature and high coercive force characteristics, but which is of secondary origin. For sedimentary rocks, especially red beds, thermal experiments alone are insufficient for unravelling complex magnetisation sequences; chemical leaching must also be performed[11]. A.f. experiments are not obligatory but are considered extremely

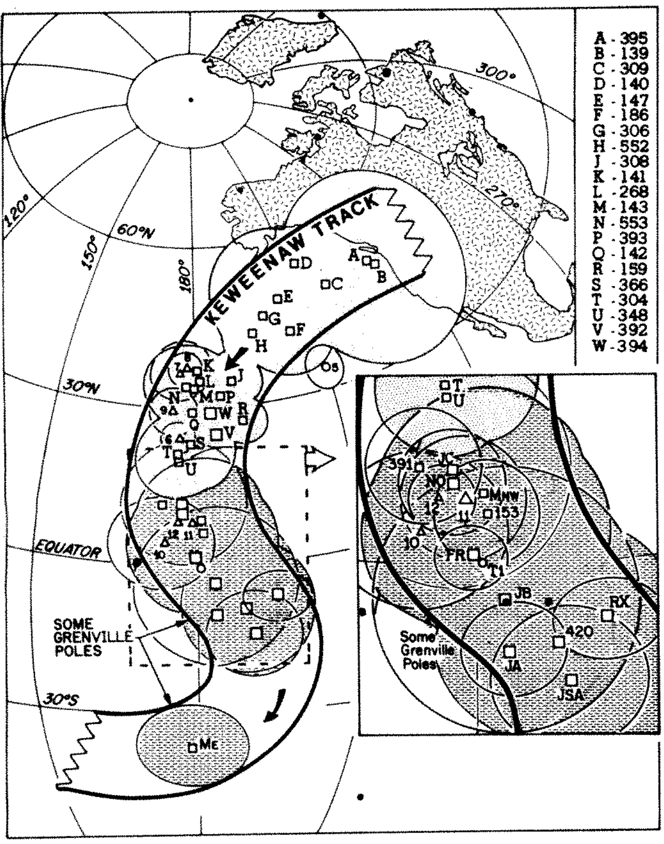

Fig. 1 Polar path for the interval −1,150 to −1,000 Myr-relative to North America. Inset shows detail of the descending portion of the Grenville Loop. Poles A→W and those with three digits are listed by their Ottawa Catalogue number[25]; △, poles (enumerated 5–12) from sequential strata in the Grand Canyon Supergroup[12]; all other poles catalogued by letters are referenced in the text. □, Site unit weight; ○, sample unit weight. Lambert equal area projection centred on 180°E, 30°N.

valuable. These requirements might seem stringent, but to understand complex geological processes, palaeomagnetic data of the highest quality possible are required. Applying these criteria to this data set, some poles can be regarded as key reference poles (KRP), shown as the larger symbols in Figs 1–3, and discussed in the detailed formulation of our polar path.

The Grenville Loop

The downward portion of the Keweenawan Track (Fig. 1), which has been established for a few years, is based on a number of KRPs from the Keweenawan volcanic sequences, for example, the Portage Lake Lavas (pole 492) is the mean of several studies. This trend is confirmed by eight poles (5–12) from a measured stratigraphic sequence in the Grand Canyon Supergroup[12]. Pole 11 near the equator from the Cardenas Lavas with a Rb/Sr isochron age of 1,090±70 Myr (ref. 13) is not significantly different from pole 391 (the Rama diabase)[26] suggesting consanguinuity of these intrusive and extrusive units of the Grand Canyon Supergroup.

Extension of the polar path southwards over the equator is based on the evidence of four new poles; the Nonesuch Shale (NO) (ref. 14), the Freda Sandstone (FR) (ref. 14), the Rapitan Group (RX) (ref. 15), and the Jacobsville Formation (JC→JB→JA→JSA) (ref. 16). All these results were obtained after extensive chemical, thermal and a.f. experimentation. The Nonesuch and Freda poles sampled over a 900-m section indicate a southward trend. Pole RX from the Rapitan Group is the direction most persistent after chemical leaching. The Jacobsville was sampled over a lateral distance of 350 km in three areas: Sault Ste Marie (C), Marquette (B) and the Keweenaw Peninsula (A). Although there is no direct stratigraphic control over the relative positions of these three areas, isopach maps[17] indicate the age sequence should be C→A. The pole JSA obtained from nine sites (including a field reversal) brings the polar path to 15°S in the descending portion of our Grenville Loop. It is most interesting that the previously underemployed pole 420 from the Shabogamo Gabbro[8] near the Grenville Front falls between poles RX and JA. From this downward-trending limb the polar path is connected to the southern end of the Grenville Track through the Grenville pole Me (Mealy Mountain—east component)[8].

The north-trending Grenville Track is based on detailed studies of polyphase magnetisations[3–6, 7–8]. In studies with two-phase magnetisations the remanence component with lower blocking temperature, lower coercive force characteristics (Grenville Group B poles) plot to the north of the higher blocking temperature, higher coercive force magnetisations (the Grenville Group A poles). Assuming that these magnetisations record a simple slow cooling exhumation TCRM–TRM, the designated age sequence then would be from south to north. A TCRM thermochemical remanent magnetisation, is to be expected as chemical changes are bound to occur during any extreme reheating (metamorphism) event. Support for this simple TRM hypothesis is provided by the record of A group poles carried by both magnetite and haematite in studies from the Magnetawan metasediments[10], and the Haliburton intrusives[6].

The poles are labelled as in Fig. 1. □, Site unit weight; ○, sample unit weight; ●, Grenville Province dyke poles; △, Grand Canyon pole (13). Solid plots indicate individual site mean poles from the post-metamorphic Grenville Province dykes[23]. Approximate error ovals are plotted individually. Lambert equal area projection centred on 330°E, 60°N.

Detailed experimental work on the Allard Lake anorthosite (AL) provides particularly good evidence for a simple metamorphic TRM[19]. Only one direction was found but both polarities are present; normal carried by magnetite, and reverse by haemo-ilmenite. Where dual magnetisations of differing remanence directions are ascribed to separate magnetite and haematite remanences, the evidence for the northward shift is less convincing because of the possibility of chemical remanence overprinting (for example, poles 482 and 483 from the Morin anorthosite[18]). By comparison with the Allard Lake result (AL) it is most probable that pole 482 represents a TCRM.

On this polar scheme, poles Me and 420 from or adjacent to the eastern Grenville Province predate poles from the western Grenville Province which define the Grenville Track; this indicates that uplift cooling in the east predated cooling in the west as previously suggested[20]. The Shabogamo Gabbro (pole 420) outcrops outside the Grenville Province, however, and may belong to an earlier portion of the Laurentian Precambrian polar path. Pole Mnw obtained from a.f. experiments alone from the eastern Grenville is ambiguous; it may belong to the descending Keweenaw Track (Fig. 1) or the ascending Grenville Track (Fig. 2). Owing to lack of thermal cleaning, this cannot be resolved at present.

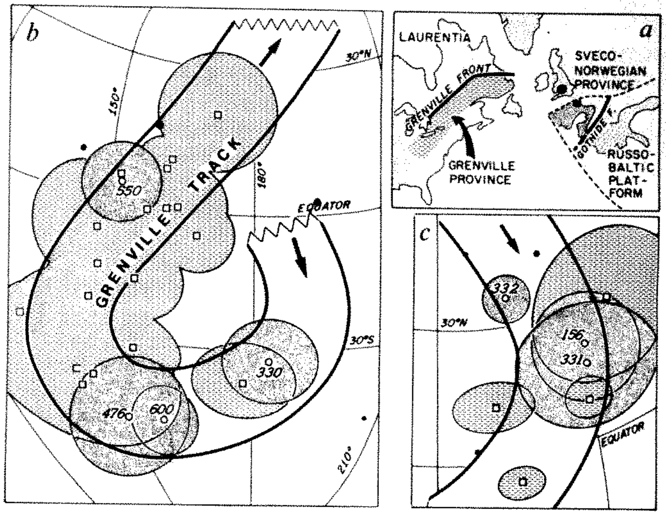
The Hadrynian Track

From about 950 Myr at 180°E on the Equator the polar path moves northwards over the present geographic north pole and then southwards to the 675 Myr Franklin KRP (450) near the Equator at 0°E. Because of the age limits on this path, we suggest the name Hadrynian Track is most appropriate.

Transition from the Grenville Loop to the north-trending Hadrynian Track is suggested by two studies, which also confirm our one-plate model. Firstly, contrary to the original suggestion[6], the magnetisation sequence A→C→B from the Grenville Province Haliburton intrusives favours a one-plate model. On a two-plate model pole (H)B lies well north of the assumed polar juncture (collision) which supposedly took place near the Equator. Also, poles 13–15 from the upper part of the Grand Canyon Suite[12] are consistent with a one-plate model, and a northward-trending Hadrynian Track if the accepted magnetisation sequence is 15→14→13. No chemical leaching was attempted on the ferruginous units 14 and 13, and it is questionable whether the initial magnetisation has been effectively isolated. Furthermore, studies of the probably correlative and contemporaneous haematite-rich Rapitan Group[15] and underlying Little Dal Lava from the Mackenzie Mountains N.W.T. indicate that secondary haematite overprints with similar poles are quite common (for example, pole RY). On the upward trend the Hadrynian Track picks up poles 422 (Stoer Group), and 167 (El Paso) both of which are dated at approximately 950 Myr, and the secondary site mean poles of the Pikes Peak Granite[21] (crosses).

For the high latitude portion of the Hadrynian Track the KRPs are RY (Rapitan Group) and J2 (Jacobsville Formation). Both these magnetisations have high blocking temperature and remanent coercive force spectra. Chemical experiments on the Rapitan indicate that RY most probably postdates RX. J2 is a CRM superimposed upon the JA, JB and JC magnetisations. Supporting evidence for the track over the pole is provided by poles Orienta 2 (T2) and Chequamegon (035) (ref. 22) which plot near the RY and J2 poles, respectively. The Orienta 1 (T1) and Orienta 2 (T2) have great similarity with JA and J2. Site poles from Grenville Province diabase dykes[23] which postdate the Grenville metamorphic episode can be divided into two groups, one tightly grouped about the Franklin pole (450), the other group yielding poles which crudely follow the Hadrynian Track. On the downward portion of the polar path, the track passes sequentially through poles from the basal Torridon sandstone (423), the Torridon Group (001), the Fron-

Fig. 4 Comparison of poles from the Sveco-Norwegian and Grenville Provinces. *a*, The proposed reconstruction as discussed in the text, showing the Gothide and Grenville Fronts subparallel. *b*, After correction to this reconstruction poles 330, 600, 476 and 550 from the Sveco-Norwegian Province gneisses are not significantly different to poles (hatched cloud) from the Grenville Province. *c*, Poles 332, 156, 331 from late-stage dykes intruding the Sveco-Norwegian Province are consistent with contemporaneous poles (horizontally hatched) after correction to the proposed reconstruction.



tenac dykes (363), and terminates with the Franklin diabase (450) and the Tudor Gabbro (458). Placing of the latter pole on this portion of the track is in accordance with the reported K–Ar isochron age[24].

Grenville and Sveco-Norwegian Provinces

The proposed Grenville Loop accommodates all the relevant palaeomagnetic data available including Grenville poles which lie outside the Grenville Track, and the non-Grenville poles which fall close to the Grenville Track, thereby seriously favouring a one-plate model for development of the Grenville Province. Because of the geologic and radiometric similarities of the Sveco-Norwegian Province of the Baltic Shield, it is pertinent to investigate whether palaeomagnetic poles from this region are compatible with the above polar path. Previous comparisons of poles from the Grenville and Sveco-Norwegian Province have explained the residual polar discrepancy after correction to the Bullard refit in terms of transcurrent motion along the line of the Caledonides[5]. This method does not provide an exact polar match; the Grenville and Sveco-Norwegian Tracks are still seen to cross-cut one another. As shown in Fig. 4 an exact match of the poles can be achieved by a 30° clockwise rotation of the Baltic Shield about a Euler pole at 170°E, 40°S after first correcting to the Bullard reconstruction. Poles 330 and 476 (Rogaland basement) and pole 600 from the Farsund intrusion[27] plot near the base of the Grenville Loop, while pole 550 (Bamble area)[28] plots close to the end of the Grenville Track. Poles from the Hunneadalen dykes (332) and Egersund dolerites (156, 331) which have been dated by K–Ar at approximately 660 Myr are shown to bear the same relationship to the Sveco-Norwegian Province as the Grenville Province diabases do to the Grenville Province. In this configuration the Gothide Front, which is sub-parallel but not colinear with the Grenville Front, is seen to form the southern margin of a unified Grenville–Sveco-Norwegian Province. The Grenville Front forms the northern boundary. This reconstruction further confirms our case for an integral single plate unit consisting of the Grenville–Laurentian, and Sveco-Norwegian–Baltic Provinces during the remanence blocking, caused by metamorphic cooling in the Grenville and Sveco-Norwegian Provinces. In conclusion, however, it does in itself pose another fundamental question: what mechanism was responsible for the intense remobilisation of the Grenville Province between 1,050 and 950 Myr?

Detection of optical pulses from the Vela pulsar

PULSED optical emission has been detected from the Vela pulsar, PSR 0833-45. Double pulses were detected from an area which included Lasker's[1] star M. The pulsed emission has a time-averaged blue magnitude of approximately 25.2 min.

The observations were made on three nights, 24–27 January, 1977, at the *f*/15 focus of the 3.9 m Anglo-Australian Telescope, Siding Spring, Australia. A twin photometer with two apertures, each 5.0″ arc in diameter, spaced by 17.5″, was used for all observations. Its two photomultipliers had S-20 photocathodes and were used without filters. The signals were fanned out to three experiments which were made as independent as possible.

In the first pulse, counters connected to each photomultiplier were sampled every millisecond by the telescope's instrument computer system, the data recorded on magnetic tape, and simultaneously binned at the apparent pulsar period for on-line display. The UTC of each sample was established with an error in epoch of ±1 ms and in frequency of one part in 10^9 using shortwave radio time-signal transmissions. The candidate position was interchanged from one aperture of the photometer to the other at intervals of about 1 h. Pointing and guiding were estimated to be reliable to 1 arc. As a check on our techniques, the Crab pulsar also was observed each night.

In off-line analysis the magnetic tape data were synchronously integrated at the apparent pulsar period in blocks of about 1 h duration. These profiles were then added in the correct phase by computing arrival-times at the solar-system barycentre. Data for the pulsar barycentric period used in this analysis were obtained from the continuing series of pulsar timing observations[2] at the NASA Deep Space Station, Tidbinbilla, at a frequency of 2295 MHz. Radio observations were made before and after the optical observations.

Table 1 Observations in Vela field

No.	α(1950) h min s	δ(1950) ° ′ ″	Integration time (h)	Description
1	08 33 39.35	−45 00 08.6	6.34	Radio position from ref. 4
2	08 33 39.26	−45 00 11.7	1.85	Position of star M as given in ref. 1
3	08 33 39.35	−45 00 06.6	1.17	2″ arc N of radio position[4]
4	08 33 39.43	−45 00 13.2	0.33	0.07 s E of the star B2 0.8″ E, 4.6″ S of radio position[4]

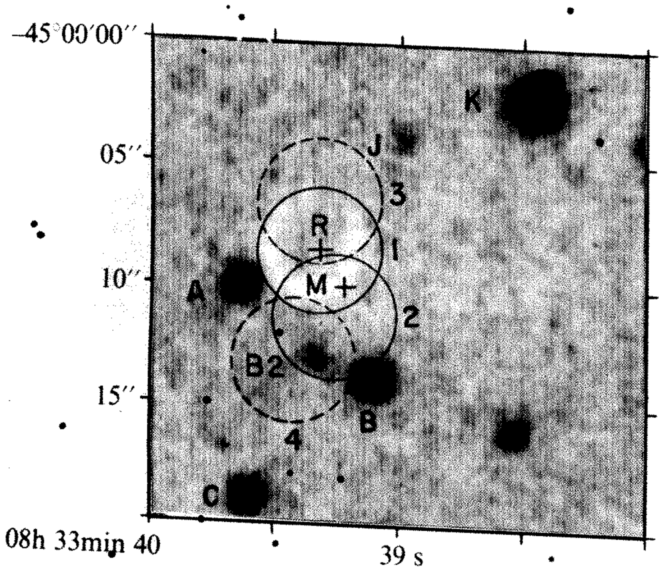

Fig. 1 The field of the Vela Pulsar as it appears, shear distorted, on the TV monitor of the Anglo–Australian Telescope. Circles 1 and 2 enclose the areas of sky where pulses were detected. The radio position (R) of Goss *et al.*[4] and the position of star M are indicated by crosses. No pulsed light was detected from the areas of sky enclosed by the dashed circles 3 and 4. The white circle enclosing the radio position is a fiducial mark in the TV monitor.

In experiment 2, the data were integrated on-line in a Fabri-Tek signal-averager at the appropriate Doppler-shifted period. The period was generated by a Monsanto frequency synthesiser. The start of each run was initiated by the observatory clock but thereafter the frequency synthesiser ran on its own internal oscillator. The third system fed signal and timing pulses to an analogue tape recorder.

Astrometric measurements made from an AAT prime focus plate of stars in the Vela field agreed with those of Lasker *et al.*[3], for their stars A, B, C, F, G and K, but disagreed with the positions given by Lasker[1] for stars A and M. Our position (1950.0) for star A is α = 08 h 33 min 39.68 s±0.03 s, δ = −45°00′ 09.9″±0.3″, and for star M (measured from the photograph by Lasker[1]), α = 08 h 33 min 39.22 s±0.03 s, δ = −45°00′ 10.1″±0.33″.

A total of 10 h observation was obtained at the four positions listed in Table 1 and shown in Fig. 1. Pulses were observed only at the radio position[4], which has errors of Δα = 0.04 s, Δα = 0.8″, and at position 2. Figure 1 shows, with our measurement of its position, that Lasker's star M was within the overlap of the apertures for both of these. Light curves for the observations are shown in Fig. 2, together with the curve obtained by summing the data from the two positions. Figure 3 shows a single curve from the multi-channel analyser system, which gives results in close agreement. The phase of radio pulse (corrected for delay due to dispersion) and γ-ray pulses[5] relative to the optical pulse are also indicated in Fig. 2. Unlike the Crab pulsar, the Vela pulsar emissions in different wavelength regimes are at different phases. The optical pulse shape is double peaked with a component separation of 22±2 ms. The second pulse is stronger, but further observations are required to investigate detailed pulse structure. The radio pulse which is essentially single-peaked, is emitted 20±2 ms before the first optical pulse. This places the optical pulses symmetrically between the γ-ray pulses, which have a separation[5] of 35 ms.

The fact that Lasker's star M was within the aperture at both positions 1 and 2 where pulses were detected allows the possibility that this is the pulsar. Some support for this is given by the slightly greater intensity of the observed pulses at position 2 for which the star M is closer to the centre of the aperture. (The seeing during the observations was generally between 1″ and 2″.) Lasker finds that star M has a B-magnitude of 23.7 with an assumed error of ±0.5. We estimate the time-averaged blue magnitude of the pulsed emission to be 25.2 with the same assumed error. This estimate is based on comparison with the Crab pulsar[6], which has a B-magnitude of 17.0. We assume that the Vela pulsar was wholly within our diaphragm for all observations at positions 1 and 2 and that it has the same colour as the Crab pulsar. Measurements of the B sky brightness at the South Celestial Pole by the UK Schmidt Telescope Unit on the three nights of our observations imply a similar magnitude for the Vela pulsar. At face value,

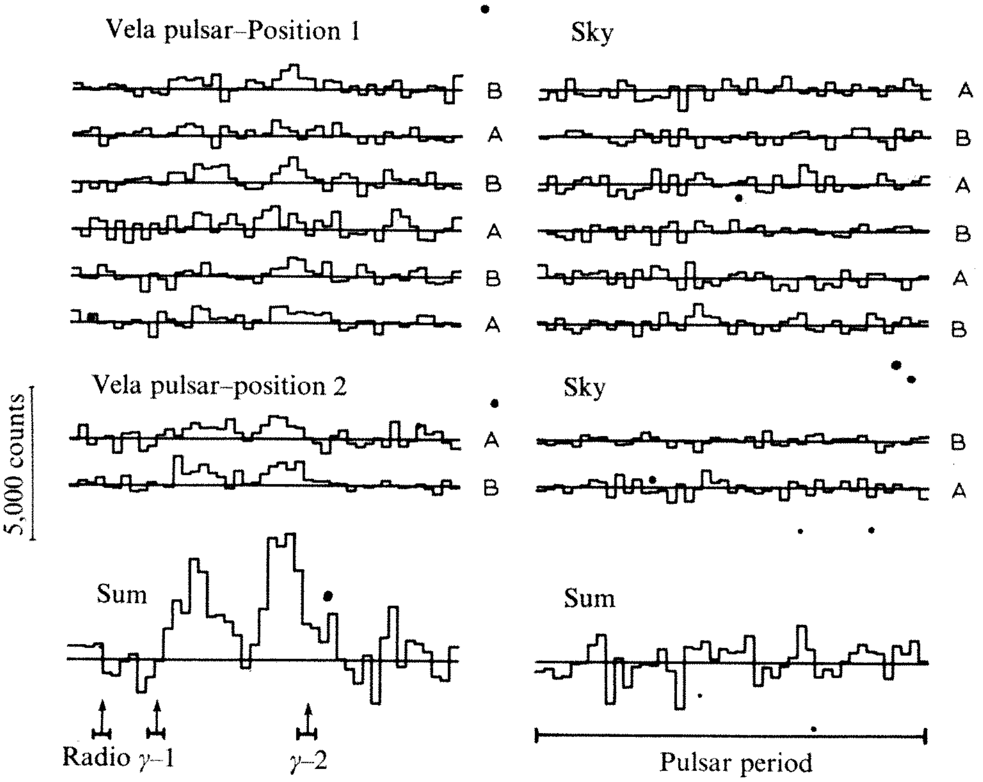

Fig. 2 Phase plots of the light curves of the pulsar (left) and simultaneous sky noise (right) as seen through the twin apertures A and B. Data have been binned to 2 ms resolution. Position 1 is centred on the radio position[4], and 2 on Lasker's position[1] for star M. Phases of emission of the radio pulse[2] with respect to the optical pulses, and of the two γ-ray pulses[5] with respect to the radio pulse are indicated at the foot of the figure. The indicated levels of the background were determined by averaging the baseline regions outside the optical pulses. For the summed pulsar profile the background was 334,800 photocounts per 2 ms bin. The corresponding level of the sky channel was 319,300.

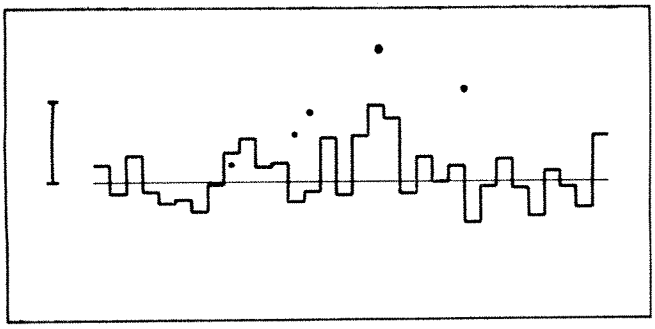

Fig. 3 The first hour long run with the second experiment, on the radio position, displayed in 32 bins. In common with the first experiment every comparable run shows the double peak, subject to photon statistics. The vertical bar is twice the Poisson dispersion.

and assuming conventional values for the distances[7], these magnitudes imply that the dependence of pulsed luminosity on period for optical pulsars follows a P^{-12} law (compare with ref. 8).

Further observations are required to determine whether or not star M is the pulsar and, if so, what fraction of its light is pulsed.

Search for γ-ray bursts with coincident balloon flights

WE report on an experiment to search for cosmic γ-ray bursts of the type discovered by Klebesadel *et al.*[1], but of smaller size and of sufficient frequency of occurrence to be detected during a 1-d observation program. Two similar detectors, successfully balloon-borne from launch sites in South Dakota and Texas, achieved about 20 h of simultaneous operation at several millibars atmospheric depth, with continuous separation of over 1,500 km on 10–11 May 1975. Fluctuations of the counting rates of >150 keV photons with temporal structures from microseconds to several minutes were compared in order to detect coincident or associated responses from the two instruments. The results of this experiment can be summarised as follows. First, no coincident γ-ray burst events were detected. Second, the resulting integral size spectrum of small bursts, from this and from all other searches, remains a spectrum of upper limits, consistent with an extrapolation of the size spectrum of the largest known bursts, fitting a power law of index −1.5. Third, a curious effect was found which can be described as consisting of associated, but not coincident, counting-rate increases of photons of energy >150 keV. This phenomenon undoubtedly presents a background, event-confusion problem for any single γ-ray burst instrument, placed either on balloons or on satellites which orbit the Earth beneath the trapped radiation.

This experiment was designed to investigate the possibility that cosmic γ-ray bursts could be detected in the size region of 10^{-7} to several times 10^{-6} erg cm^{-2}, below the apparent bend in the size spectrum of Vela events as described by Strong and Klebesadel[2]. It has generally been assumed that the observed bend could be due to instrumental effects[3–5] (because the detector thresholds do not produce a sharp cutoff in event selection, due to the widely varying temporal structures of the bursts). An intrinsic bend in the true size spectrum, however, would be of great interest. A plot of $N(>S)$, the number of events of size greater than S, as a function of event size S, would vary as $S^{-1.5}$ for an extended volume of source objects positioned essentially isotropically, but as S^{-1} for a disk-shaped region and as $S^{-0.5}$ for a one dimensional source region. Thus, the shape of the observed size spectrum not only could indicate a galactic structure in the γ-ray burst source pattern, but also might directly calibrate the intrinsic source strength distribution from the known galactic dimensions.

Our first experiment to search for small γ-ray bursts was the balloon-flight of a single large detector in May 1974—a number of candidate events were found, having sizes consistent with −1.5 index power-law extrapolation, but which could not be established as true γ-ray bursts without confirmation from another detector[3,6].

To obtain a more definite signature for cosmic γ-ray bursts, the dual balloon experiment described here was carried out in 1975. Two similar detectors were flown simultaneously with adequate geographical separation to avoid local cosmic-ray or magnetospherically induced coincident responses. One balloon was launched at 0145 UT on 10 May from Palestine, Texas and floated until about 0400 UT on 11 May. The other balloon was launched about 0340 UT on 10 May from Sioux Falls, South Dakota and floated until 2125 UT on 11 May. The distance between the balloons was always greater than the distance between the launching stations, which is about 1,300 km. The total time of simultaneous float above 6.5 mbar residual atmospheric pressure was about 18 h, most of which was above 3.5 mbar depth.

The detector in each instrument consisted basically of a plastic scintilator 8,900 cm^2 in area and 5 cm thick, viewed by two 5 inch PM tubes in coincidence. The absolute energy threshold was at ≈150 keV, although calibration with radioactive sources showed that the average effective threshold was nearly twice this figure. Particles were excluded by a second, anticoincidence threshold set at 2.5 MeV. In each instrument a time interval analyser (TIA) (ref. 7) was used, measuring the time interval ΔT between each pair of successive photon counts. Thus, rapid, short countrate increases (fast bursts) could be evident in a rate against ΔT histogram as bumps in the region of small ΔT, well separated from the main, Poisson distribution of background γ-ray counts. This made possible a search for temporal structures in counting rates from the 40-ns region continuously to the several hundred millisecond region, with longer structures evident from the use of the total counting rate histogram. The advantage of this system over the conventional counting rate histogram scheme is that orders of magnitude lower bit-rate telemetry can be used. Absolute time coincidences between the two detectors would have been attainable to 72 ms resolution, except that an electronic problem resulted in an actual accuracy of only 1 s. Therefore, coincidences of increases of less than 1 s duration could only be inferred from their likelihood of occurrence in coincident data samples.

The data analysis showed that indeed non-Poisson counting rate excursions were detected with time bases from the microsecond region to the 1-min region. These could be due to local background such as cascade showers, neutron and cosmic-ray interactions and induced radioactivity, and to magnetospheric effects. A phenomenological data treatment was therefore developed, consisting of plots of the number of fluctuations against size in standard deviations, against time base on a logarithmic scale. For each of the two instruments, a smooth, three-dimensional distribution was found to contain only one bump, other than the background distribution having a maximum near the origin. In each case this extra population consisted of very long, one half to several minute, counting rate increases of many standard deviations value. No extra population was found in the 0.1–20 s region where all known γ-ray bursts occur. All increases of over a few standard deviations from each instrument of any time character from microseconds to minutes were compared, however, to search for correlated increases from the two detectors. The results were that, except for those expected on a random coincidence basis, none occurred other than the very long time-base population found with the plots, as described above.

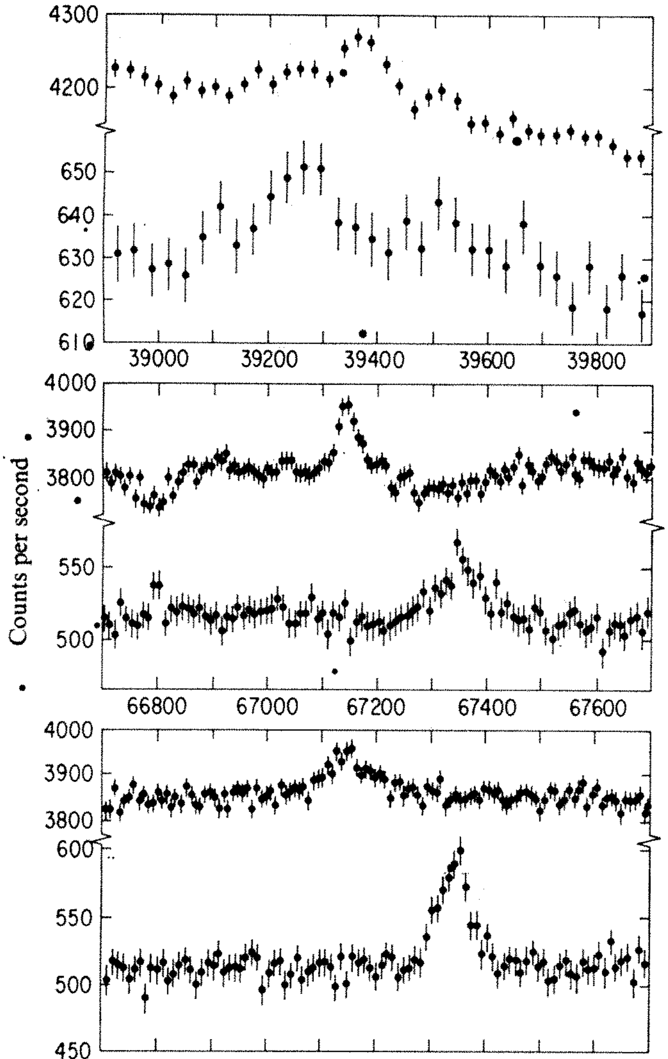

Fig. 1 Counting rate increases exhibited by the γ-ray counters in three occasions. In each record Sioux Falls data are uppermost with Palestine data below. The lack of simultaneity of the events in each case disproves cosmic origin; the fact that the pairs of increases are always separated by a short time delay relative to the time between their occurrence argues for a magnetospheric origin. Such transient increases present a background problem for near-Earth γ-ray burst detectors.

Time histories of the most significant counting rate increases are plotted in Fig. 1*a–c*. (The sensitivities of the two instruments are not the same, but, due to a minor malfunction, the rates of Palestine instrument are somewhat less, and are switched off for 5 s out of each 10 s.) If these increases were γ-ray bursts, assuming the spectrum found typical of longer events[8], their energy content would be around 10^{-5} erg cm^{-2} each. They are clearly not coincident, however. The light travel time between the two detectors is only 5 ms, and yet the temporal separation is many tens of second. The increases are surely associated, however, since there are only several of these events in either tabulation of single counting rate histograms within the 18 h. Thus, the probability is negligible that each pair should fall within a few minutes separation on a random basis. One explanation of this phenomenon may lie in ionospheric or magnetospheric activity with a slowly travelling disturbance centre. Artificial sources are a less likely explanation. We have checked the VLF receiving records of the Naval Observatory in Washington, D.C. Records were available for the VLF stations WLK, Jim Creek, California, and NBA, Balboa, Canal Zone, and for the Omega stations Trinidad and LeMoure, North Dakota. None of these records show any disturbance during the day of 10 May during which three of our events occurred. The responsible electron fluxes would have to be small, less than one per cm^2, such that, if magnetospheric, they lie outside the domain of typically studied trapped radiation phenomena. Such counting rate increases are clearly a danger to any experiment seeking to measure γ-ray bursts without confirmation. In either single balloon flight, these events could have been taken to be exceptionally long γ-ray bursts, were it not for the lack of coincident information in the other. It must be added that one associated event took place near local midnight, so it could not be of solar origin (solar flares would also, of course, be seen as exactly coincident). Thus the need is evident for more sophisticated techniques to search for small γ-ray bursts, a need that applies to low-orbiting Earth satellites instrumentation, as well as to balloon flights.

Figure 2 shows the upper limits to the size spectrum of γ-ray bursts resulting from the analysis of our data. We have included 95% upper limits on the basis that we did not see any actual events in our 1975 flights; the energies where we put our upper limits depend on the time increment used for the burst search. The left mark is the result of a separate 0.1-s search. Since the 0.1-s events are a fairly rare subgroup of events in the total amount of satellite data[9], we regard the results obtained by balloons to date as inconclusive so far as the slope of the size spectrum is concerned. We feel that this unfortunately remains true when the other balloon data, as plotted on this graph, are included. A recent note[10] indicates our reasons for interpreting the results of another balloon experiment search[11] as also consistent with no size spectrum slope change. That note enumerates a number of factors which contribute to rendering a balloon-borne search for bursts less efficient than it may have been intended to be. Our conclusion from this experiment, and from various others[12–14] is that we need an increase in sensitivity by another order of magnitude to be able to adequately detect small γ-ray bursts. If that

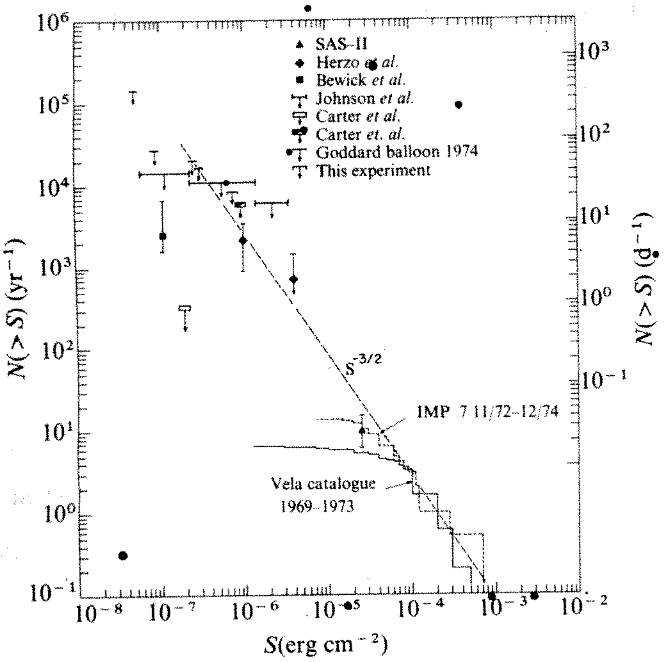

Fig. 2 A plot of the size spectrum of known, large γ-ray bursts and of the various upper limits to the intensity of small bursts, obtained from this and other balloon-borne searches.

can be done, the next step, observing a source direction anisotropy, may be possible.

We thank G. Porreca for design of electronics, and H. Costlow and C. Thomas for preparation of the gondolas and assistance with flight operations.

Possible γ-ray line from the Crab Nebula

A BALLOON-BORNE γ-ray telescope was flown on 10–11 May 1976 from Alamogordo, New Mexico to search for celestial γ-ray lines in the energy range 100 keV–5.0 MeV. We report here evidence for a line feature from the Crab Nebula at 400±1 keV. Although the counting statistics do not allow us to make an incontestible claim, the fact that it occurs at a reasonable energy to be gravitationally redshifted positron annihilation radiation occurring at the surface of the Crab Pulsar, and in all respects seems to be a real astronomical line, has encouraged us to bring this to the attention of the astronomical community.

The design of the telescope is described in the legend of Fig. 1. A total of 7.4 Crab target and 7.4 Crab background segments were obtained from an altitude of ~ 122,000 ft with zenith angles of 12–57°. An additional 27 segments were obtained from other astronomical sources. The pointing accuracy of the system was about ±1° with the effective entrance aperture increasing slowly with energy from 11° FWHM at 59 keV to 13° FWHM at 1.33 MeV.

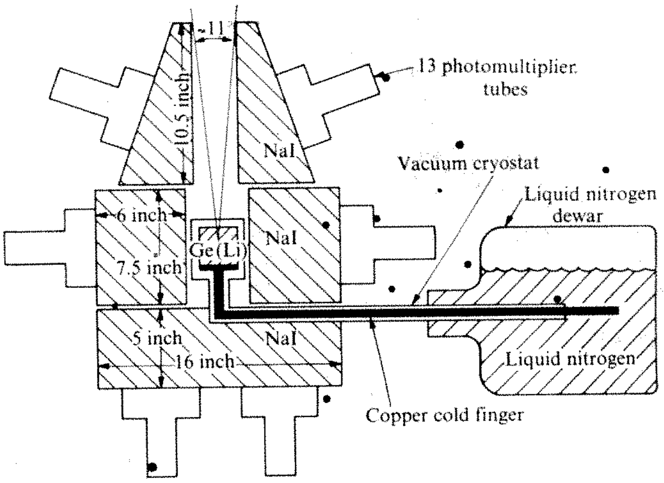

Fig. 1 Schematic diagram of the apparatus. The telescope was designed for optimum sensitivity to lines and contained a 4.70-cm diameter by 6.35-cm long lithium drifted germanium Ge(Li), detector surrounded by 400 pounds of active NaI operated in anticoincidence with the central Ge(Li) detector. The NaI served to collimate the Ge(Li) detector, shield it against atmospheric γ-rays and insure that only full energy events are recorded. Ge(Li) pulses not vetoed by a coincident shield pulse pass through a preamplifier, a shaping amplifier and finally are stored in the onboard memory of a 4096 channel pulse height analyser. The energy resolution of the system below 2 MeV was 3.4 keV FWHM. Data were accumulated in alternate 20-min target-background segments, with the telescope rotated in azimuth 180° but maintained at the same zenith angle for the background measurements.

In Fig. 2 the Crab Nebula difference spectrum extrapolated to the top of the atmosphere is plotted, clearly showing the detection of the X-ray–γ-ray synchrotron continuum at energies below several hundred keV. Also shown is our best fit power law which seems compatible with other recent measurements[1,2]. Beyond 1 MeV the quality of the continuum data has degenerated to the point that the spectrum becomes

*Lines used in transforming analyser spectra to energy spectra.

Apart from the line at 400 keV, all lines appear with comparable statistical significance in the Crab background spectrum and with enhanced significance in the composite spectrum.

consistent with zero net counts from the Crab. Manipulations of the raw data made in obtaining this spectrum deal with the effects of atmospheric attenuation, detector efficiency, system dead time and drifts in the calibration of the energy axis during the course of the flight. Atmospheric attenuation corrections were based on altitude measurements provided us by the Air Force Geophysical Laboratory Balloon Group, using a mean standard atmospheric model confirmed by rocket measurements on flight day. Photopeak detector efficiency as a function of energy was obtained from elaborate Monte Carlo calculations confirmed by laboratory measurements at 14 discrete energies. The high effectiveness of the anticoincidence shield in suppressing the Compton tail and the steepness of the energy spectrum justified the neglect of down-scattered photons. Dead time corrections based on careful laboratory measurements were generally of the order of 20%, due primarily to veto counts in the NaI shield. To correct for system drift in transforming from pulse height analyser channel spectra to energy spectra we first determined the peak channels, in each record, corresponding to five lines at known energies which appeared clearly in all records. Energies corresponding to other channels were then determined by linear interpolation or extrapolation.

We made a careful search of the data for potential sharp line features from the Crab Nebula, by searching both the target and the background data for 5-keV wide bins which contain > 3σ excess number of counts over what would be expected based upon the two 10-keV wide bins on either side of the 5-keV wide bin in question. A total of 12 lines were detected which appear in both the target and background data. These are listed in Table 1 with some tentative identifications. Apart from the ^{207}Bi lines, which are from an onboard radioactive calibration source, most of the remaining lines can be understood in terms of cosmic-ray induced nuclear transitions in the telescope structure and have been seen by other investigators with comparable intensity and width[3,4].

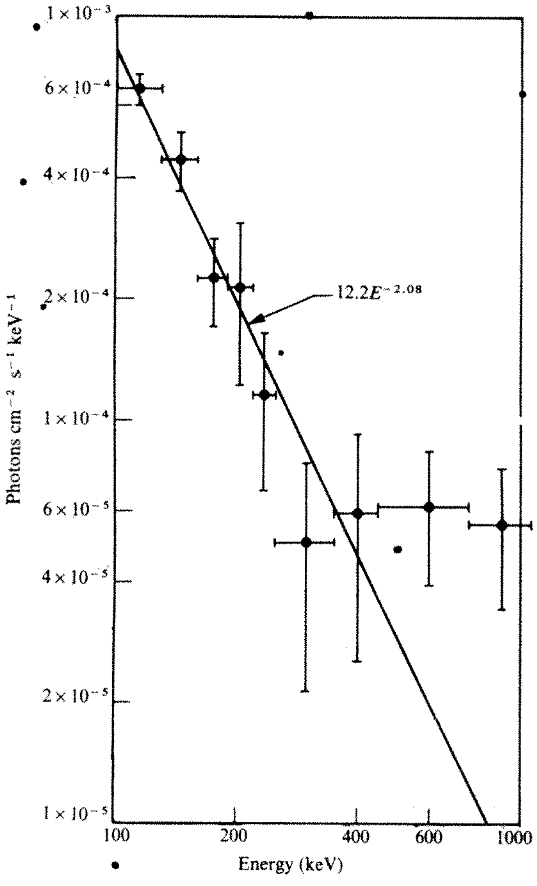

Fig. 2 Energy spectrum of the Crab Nebula's total emission at the top of the atmosphere. The solid line is the power law that best fits the experimental data. The data have been collected into 30-, 100- and 300-keV bins to reduce the statistical scatter of the points.

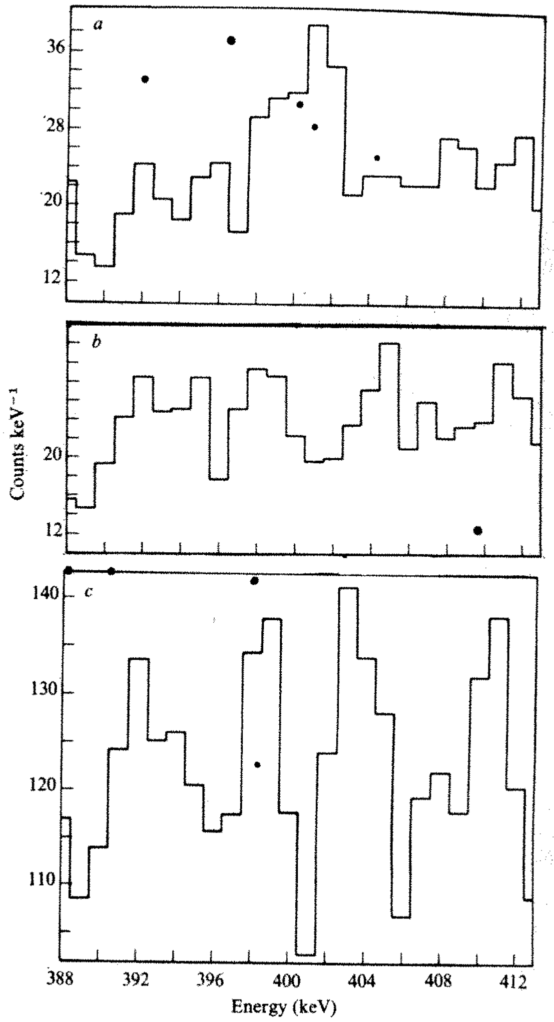

Fig. 3 *a*, Crab target and *b*, Crab background energy spectra in the vicinity of 400 keV; *c*, a composite spectrum of all data less Crab target segments.

In addition to the lines mentioned above, one potential line feature has been detected at 400±1 keV in the target data but not in the background data. Both the Crab target and Crab background spectra in the vicinity of 400 keV are shown in Fig. 3, with a spectrum consisting of a sum of all our data excluding the Crab target segments. These spectra are basically raw data, having been corrected only for drifts in the energy calibration with time. It is believed that the telescope continuum at this energy is dominated by leakage of the atmospheric γ-ray background through the NaI shield. The fact that the feature appears only in the Crab target spectrum is taken as strong evidence that it is not a telescope artefact. It is also important that the line is evident in most of the target segments. The feature represents a 4.0σ deviation above the telescope continuum as determined from the 387.5–397.5 and 402.5–412.5 keV energy bins of the target spectrum. Although the above method was originally used, there are many other valid ways to search the data for lines, each yielding a slightly different level of significance for the 400-keV feature, for example, one can vary the width of the relevant energy bins, theoretically extrapolate the data to the top of atmosphere before searching for lines, use the Crab background data for continuum subtraction, etc. Using these methods, the level of statistical significance can be made to vary from ~ 3.3σ to ~ 4.2σ. Clearly, the probability that the feature is a statistical accident is not negligible, and definitive proof of its reality must await further experimentation. After correcting for atmospheric attenuation and dead time, the feature in Fig. 3 corresponds to a line flux of $2.24 \pm 0.65 \times 10^{-3}$ photons s^{-1} cm^{-2} incident upon the Earth with a width $\lesssim 3$ keV. Such a line flux could have produced a feeble feature in the previously most sensitive search for lines from the Crab Nebula[1] made with an instrument of much poorer energy resolution. The absence of a strong indication of it in these earlier data signals a note of caution in accepting the reality of the present result.

Finally, it is interesting to consider a possible physical origin for the feature. Several mechanisms exist for generating positrons at or above the surface of the Crab neutron star[5,6]. Positron annihilation in dense gases and solids usually results in the emission of 511 keV photons. Should this occur near the stellar surface, the photons would appear to us gravitationally redshifted. This measurement then determines $Z_{\mathrm{Crab}} = 0.28$ (assuming no other sources of frequency shift). Recent neutron star models[5,7] can then be used to determine the mass of the Crab yielding ~ 1.4 $M_{\odot}$ which is not unreasonable[7]. For this hypothesis to be correct, ~ 10^{41} positrons s^{-1} must be annihilating into 511 keV photons near the neutron star surface (assuming isotropic radiation) which then reach Earth without significant Compton scattering. A more detailed report of the experiment will be published elsewhere.

Interpretation of observed cosmic microwave background radiation

THE observed cosmic microwave background radiation, which has a high degree of spatial isotropy ($\Delta T/T \leqslant 10^{-3}$) and which closely fits a 2.7 K black body spectrum, is generally claimed to be the strongest piece of evidence in support of hot big bang cosmologies by its proponents (for a recent review see ref. 1). Alternative explanations in terms of the integrated effect of a suitable population of extragalactic radio sources[2–6] have been criticised, essentially on the ground that there is no known population of extragalactic objects with a source density sufficient to explain the observed small-scale isotropy of the microwave background[7]. We report here that the 'surface of last-scattering' of the observed microwave background radiation corresponds to the distribution of dust in galaxies or protogalaxies with a temperature ≈ 110 K at the epoch corresponding to $Z \sim 40$, and not to a plasma of temperature $\gtrsim 3{,}000$ K at an earlier epoch ($Z \gtrsim 1{,}000$), as given by the canonical model of big bang cosmologies. The claim that this radiation lends strong support to hot big bang cosmologies is without foundation.

Wickramasinghe *et al.*[8] assumed the existence of dust uniformly distributed in intergalactic space. Absorption and re-emission of radiation from galaxies by these grains then produce the microwave background radiation. This dust must have special geometrical properties to make the metagalaxy up to the Hubble radius optically thick around $\lambda \leqslant 2{,}000$ μm, but allowing it to be transparent in the visual range. Based on radar scattering data for thin wires, semiconducting needles (for instance, graphite) with length $l \approx 100$–$1{,}000$ μm and cross-sectional radius $a \ll l$ are expected to have this effect, as they seem to produce a strong peak in the absorption cross-section around $\lambda \approx 2l$. Also, the required intergalactic dust density of 10^{-34} g cm^{-3} is not incompatible with upper limits set by other methods[9,10].

The observation of very distant discrete radio sources down to mm wavelengths presents a serious difficulty for this model. The QSOs with the two largest red shifts (OH 471 at $Z = 3.40$ and OQ 172 at $Z = 3.53$) are at distances from us of 0.90 R_0 and 0.91 R_0 respectively (where R_0 is the present Hubble radius). Yet they both indicate a second maximum in their emission spectrum[11] at $\lambda \approx 3{,}000$ μm, where the above model implies an optical depth $\gtrsim 4.5$.

We therefore conclude that the microwave background radiation must be explained not in terms of a coupling between matter and this radiation at the present epoch, but in terms of a coupling in a previous epoch within the framework of an evolutionary cosmology.

Rather than specifying a certain evolutionary cosmology (that is, the 'initial conditions'), let us merely go back in time from the present epoch. If the coupling between the radiation and matter occurred when the radius of the metagalaxy was R, then the common thermal equilibrium temperature of matter and radiation is given by

$$T_B \approx 2.7\,(R_0/R)\ \mathrm{K}, \qquad (1)$$

while the wavelength of maximum radiation is given by

$$\lambda_m \approx 1{,}800\,(R/R_0)\ \mu\mathrm{m}. \qquad (2)$$

Provided the total number of absorbers of the radiation at any given wavelength λ is conserved, the optical depth of the metagalaxy at λ is given

$$\delta(\lambda) = \delta_0(\lambda)\,(R_0/R)^2 \qquad (3)$$

where δ_0 is the optical depth at present. If the absorbers are uniformly distributed in the metagalaxy with a present number density n_0 and cross-section $\alpha(\lambda)$, then

$$\delta_0(\lambda) = \alpha(\lambda)\, n_0 R_0. \qquad (4a)$$

If, however, the absorbers are concentrated in galaxies then

$$\delta_0(\lambda) \approx \delta_g(\lambda)\, N_{0g} S_g R_0, \qquad (4b)$$

where $\delta_g(\lambda)$ and S_g are respectively the average optical depth of a galaxy at λ and its average geometrical cross-section (which are assumed to remain unchanged), and N_{0g} is the present number density of galaxies in the metagalaxy.

If the absorbers are uniformly distributed in intergalactic space, one can easily make the metagalaxy optically thick[8] at epochs given by $R/R_0 \leqslant 0.1$ with a present dust density $\leqslant 10^{-36}$ g cm^{-3}, without conflicting with the above observations.

Instead of postulating the existence of an unobserved population of intergalactic dust, however, we will work in terms of the known properties of dust distribution in our own Galaxy. The sources of absorption and re-emission of the radiation in past epochs are then taken to be the dust distributions in dusty spiral galaxies, which we take to be similar to that of ours. The condition needed for thermalisation of the background radiation at any epoch is given by $\delta(\lambda_m) \approx 1$.

We do not know the extinction in our own Galaxy at far infrared wavelengths, but the visual extinction $A_g(\lambda_v)$ parallel to the galactic pole[12] for its entire thickness ≈ 0.5 m. As long as the grains have a sufficient conductivity (for example, graphite, 'dirty' ice, etc.) their extinction is expected to follow approximately an inverse wavelength dependence for $\lambda \gg 2\pi a$ (where a is the grain radius)[13,14] and there is some supporting observational evidence[15] in the range $50\ \mu\text{m} \leqslant \lambda \leqslant 1{,}000\ \mu\text{m}$. Assuming this to be the case, and taking $\lambda_v \approx 0.55\ \mu\text{m}$ we get $A_g(\lambda_m) \approx 0.5 \times 0.55\ \lambda_m^{-1}$ and a corresponding optical depth $\delta_g(\lambda_m) \approx 0.92 A_g(\lambda_m) \approx 0.25 \lambda_m^{-1}$, which is the optical depth appropriate to our calculation, as the dust is believed to be concentrated in a thin disk of thickness $\leqslant 200$ pc (ref. 16).

The total population of galaxies in the metagalaxy is also highly uncertain and depends on the highly uncertain value of the deceleration parameter q_0. Taking the current 'best estimate'[17] of q_0 to be 0.03 and assuming a negligible mass of intergalactic matter, we estimate a metagalactic population of around 2×10^{10} dusty spiral galaxies, giving $N_{og} \approx 1.2 \times 10^{-75}$. Then with $R_0 \approx 1.6 \times 10^{28}$ and $S_g \approx 5 \times 10^{45}\ \text{cm}^2$ we get $N_{og} A_g R_0 \approx 0.1$. Substituting these values in (3) and using (2) we get

$$\delta(\lambda_m) \approx 1.4 \times 10^{-5} (R_0/R)^3 \qquad (5)$$

whence $\delta(\lambda_m) \approx 1$ when $R_0/R \approx 41$. We conclude therefore that the background radiation was coupled to the galactic dust at this epoch $Z = (R_0/R) - 1 \approx 40$, when they both had the common equilibrium temperature ≈ 110 K. There is no difficulty for any type of hitherto proposed interstellar grain, including H_2O ice, to exist at this temperature.

The epoch of galaxy formation is highly model dependent and uncertain, as is the epoch of dust production. The current best estimates[18] of the epoch of protogalaxy formation in an expanding universe are $Z = 10$, 20 and 60 for $q_0 = 2$, 0.5 and 0.02, respectively, and do not apply to a universe which had a bounce in the past. Considering this and the order of magnitude nature of our own calculation, our implicit assumption that galaxies (or at least dusty protogalaxies) existed at $Z \approx 40$ is not unreasonable. Also, at $Z \approx 40$, the galaxies still occupy $\leqslant 1\%$ of the volume of the metagalaxy.

The number density of galaxies (or protogalaxies) at this epoch ($Z \approx 40$) $\gtrsim 7 \times 10^4\ N_{og}$, and this easily exceeds all lower limits for this number density of discrete sources set by the observed small-scale spatial isotropy of the microwave background radiation[7].

Just as the radiation received from the Sun gives us direct information only about its surface, the microwave background radiation gives us direct information only about the 'surface of last scattering' when the radiation finally decoupled from matter and beyond which the metagalaxy remained transparent. According to our model, this 'surface of last scattering' was the total dust distribution in galaxies or protogalaxies at the epoch $Z \approx 40$. Consequently, we cannot obtain direct information about the metagalaxy at earlier epochs ($Z > 40$), as it was then opaque. This conflicts with the detailed canonical model of the hot big bang cosmology which identifies this 'surface of last scattering' with a rapidly recombining plasma of temperature $T \approx 3{,}000$ K at a much later epoch $Z \gtrsim 1{,}000$, when the coupling mechanism between the matter and radiation was Thompson scattering (for example, see ref. 19).

Despite this conflict, however, we do not claim that the observed microwave background radiation is inconsistent either with the basic concept of a hot big bang cosmology, or with a completely different class of evolutionary cosmology, for example, the symmetric cosmology of Klein[20-22], where the minimum radius of the metagalaxy was $> 0.01\ R_0$.

We stress that the observed cosmic microwave background radiation does not give us direct information about the state of the metagalaxy further back than the epoch corresponding to $Z \approx 40$, when galaxies or protogalaxies already existed, and when its own temperature was only about 110 K. To claim that it is strong evidence in support of the hot big bang cosmology whose earliest epochs correspond to $Z \gtrsim 10^{12}$ with corresponding temperatures of matter and radiation $> 10^{10}$ K, is completely unjustified.

We thank Drs Steve Willner and Steve O'Dell for useful discussions. This work was supported by grants from NASA and NSF.

Radiative acceleration of gas above a luminous disk

Spherically symmetric radiative acceleration has been considered[1] as a mechanism for the ejection of matter from quasistellar objects. I present some calculations showing that in a simplified case, a strongly beamed outflow will result if the source of the driving radiation is not point-like but a disk.

Consider an infinitesimally thin, optically thick disk that emits thermal radiation with an intensity $I(r)$. The radiative force exerted by a surface element $r\,\mathrm{d}r\,\mathrm{d}\varphi$, situated at cylindrical coordinates $(r, \varphi, 0)$, on a spherical cloud with cross section S is

$$\mathrm{d}F = (S/c)\ [2hr\,I(r)(h^2 + R^2 + r^2 - 2rR\cos\varphi)^{-3/2}] \qquad (1)$$

$$\times (h^2 + (R - r\cos\varphi)^2)^{-\frac{1}{2}}\,(h, R - r\cos\varphi)\,\mathrm{d}r\,\mathrm{d}\varphi$$

where $(R, 0, h)$ are the cylindrical coordinates of the cloud. If the distance $D \equiv (h^2 + R^2)^{\frac{1}{2}}$ of the cloud from the disk centre is large compared with the effective disk radius, one finds by direct integration of equation (1)

$$F \simeq \frac{SL}{2\pi c}\,\frac{h}{D^3}\,\boldsymbol{e} \qquad (2)$$

where L is the total luminosity of the disk and $\boldsymbol{e}$ is a unit vector pointing radially away from the disk centre. The net force on a cloud with mass m is due to the sum of F and the gravitational attraction of the disk and its central object. If the latter is dominant and has mass M, the net force is

$$F = \frac{\boldsymbol{e}}{D^2}\left(\frac{SL}{2\pi c}\,\frac{h}{D} - MGm\right) \qquad (3)$$

Apparently, this force is directed away from the central object if

$$h \gtrsim R(4\varepsilon^2 - 1)^{-\frac{1}{2}},\ \varepsilon \equiv SL/(4\,\pi\,mc\,MG) \qquad (4)$$

where ε is the Eddington number. Equation (4) defines a cone above the disk, the opening angle of which becomes larger with

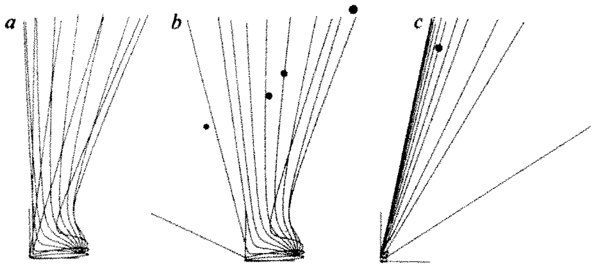

Fig. 1 Orbits of clouds in the force field given by equation (3), with Eddington number $\varepsilon = 1$. Solutions were made dimensionless by scaling with length unit r_0 (horizontal and vertical lines) and time unit $(MGr_0^{-3})^{-1/2}$. Plot marks indicate time intervals of 0.5. *a*, All initial velocities in the plane of the drawing. Initial velocity modulus 0.5, stepped by 15° from −90° to +90°. *b*, Initial velocities as in (*a*), but all with initial velocity 0.1 added tangential to the disk. *c*, Same rotated through 90°. Every cloud passing through the disk is probably stopped there, which makes the beam narrower than shown here.

increasing luminosity L. The existence of this cone is the cause of the beamed outflow. Equation (4) has solutions if

$$\frac{2\pi m}{S} < \frac{L}{MGc} = 9.62 \times 10^{-3} \left(\frac{LM_{\odot}}{L_{\odot}M} \right) \text{kg m}^{-2} \qquad (5)$$

The cloud must be optically thick, so that $m/S > m_{\mathrm{H}}/\sigma$ where σ is a scattering cross section. If σ equals the Thomson cross section, the 'cloud' is an individual particle, and equation (5) is the Eddington condition.

I have considered two types of motion in the far field (3), namely the motion of individual clouds or particles, and the motion of an atmosphere. The former is a straightforward problem of classical mechanics, which was solved numerically by a fourth order predictor–corrector method (Fig. 1). The motion of a stationary atmosphere was considered for a dust model (negligible gas pressure). In spherical coordinates (r, φ, θ) the equations for this case are

$$uu_r + \frac{v}{r} u_\theta - \frac{v^2}{r} = \frac{MG}{r^2} (2\varepsilon \cos\theta - 1) \qquad (6)$$

$$uv_r + \frac{v}{r} v_\theta + \frac{uv}{r} = 0 \qquad (7)$$

$$\rho\left(u_r + 2\frac{u}{r} + \frac{1}{r} v_\theta + \frac{v}{r} \cot\theta\right) = -u\rho_r - \frac{v}{r} \rho_\theta \qquad (8)$$

where $(u, 0, v)$ is the velocity vector and a subscript denotes partial derivation. The full equations, including azimuthal motion and a viscous dissipation term, also admit the type of similarity solutions that will be described below. These have been calculated also, but are omitted here for the sake of brevity; they are alike to the solutions given here, so that the main conclusions regarding the beaming and the influence of the Eddington number are not altered. Separating the variables by putting $v = f(\theta)\,(MG/r)^{1/2}$ and $u = -2\,(MG/r)^{1/2}\,\partial f(\theta)/\partial\theta$, one obtains the ordinary differential equation

$$2\left(\frac{\mathrm{d}f}{\mathrm{d}\theta}\right)^2 + 2f\frac{d^2f}{\mathrm{d}\theta^2} + f^2 = -2\,\varepsilon\cos\theta + 1 \qquad (9)$$

The streamlines follows from u and v as

$$\frac{u}{v} = \frac{1}{r}\,\frac{\mathrm{d}r}{\mathrm{d}\theta} = -2\,\frac{\mathrm{d}\log f}{\mathrm{d}\theta} \rightarrow r \propto f^{-2} \qquad (10)$$

The density is found from equation (8) to be

$$\rho = \psi\, r^A f(\theta)^{2+2A}/\sin\theta \qquad (11)$$

Further solutions for ρ can be generated from equation (11) by putting $\psi = \psi(A)$, solving A from $(\partial\rho/\partial A) = 0$, and substituting the solution into (11). Equation (9) has the solution

$$f = \{1 - 2\,\varepsilon[\alpha\cos\theta + (\beta + \tfrac{1}{2}\,\theta)\sin\theta]\}^{1/2} \qquad (12)$$

The boundary conditions at $\theta = \pi/2$, $r = \infty$, dictate $\beta = 1/(2\varepsilon) - \pi/4$ and $\alpha = \frac{1}{2} - \mu/\varepsilon$, where μ is a small number determining the thickness $z = r_c f^2(\theta_c)/2\mu$ of the disk at infinity. Here θ_c is the angle at which the flow is just tangential to the central object with radius r_c (Fig. 2). The boundary conditions at $r = r_c$ determine the value of ε implicitly, as follows. Integration of ρu over the region $\theta_c < \theta < \pi/2$ gives the accretion rate

$$\dot{M} = 4\pi\psi\, r_c^{A+2} f_c^{2A+3} (MG/r_c)^{1/2}/(2A+3) \qquad (13)$$

where $f_c = f(\theta_c)$. Because $L \approx 3M\dot{M}G/r_c$, it follows from equation (4) that

$$\gamma\varepsilon = f_c^{2A+3},\ \gamma = \frac{mc}{S}\,\frac{2A+3}{3\psi r_c^A}\,(MGr_c)^{-1/2} \qquad (14)$$

Now θ_c is the solution of $(\partial f/\partial\theta)(\theta_c) = 0$; because $f = f(\varepsilon, \mu)$ one has $\theta_c = \theta_c(\varepsilon, \mu)$, whence equation (14) becomes an implicit equation for ε with solution $\varepsilon(\mu)$. For given boundary conditions at $r = \infty$, there is only one ε that makes the flow fit at $r = r_c$ (Fig. 2).

To obtain the force field near the disk, equation (1) must be integrated numerically. This precludes simple analytic hydrodynamics, so I have only numerically integrated the equations of motion for individual clouds or particles in the near field (Fig. 3).

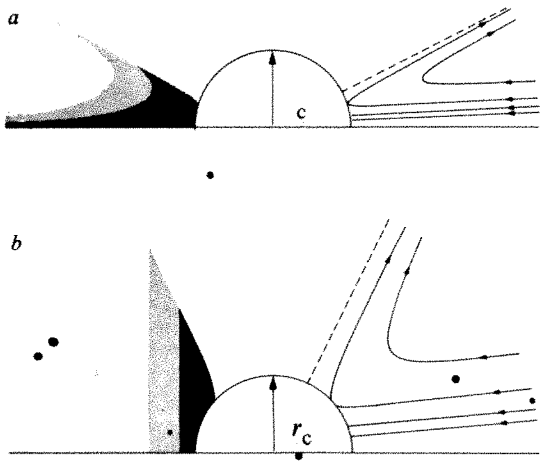

Fig. 2 Gas flow in the far field of the disk, if the gas pressure is negligible. The solutions have been made self-consistent by requiring that the accretion onto the central object with radius r_c generates exactly the luminosity corresponding to the Eddington number of the flow pattern. *b*, $A = -1$ [see equation (1)], $\mu = 0.01$; these parameters imply $\varepsilon = 1.42$ and a disk thickness at infinity of $z = 4.74\ r_c$. *a*, $A = -1.25$, $\mu = 0.01$, yielding $\varepsilon = 3.43$ and $z = 0.98\ r_c$. It has been assumed that σ equals the Thomson cross section, $\psi r_c^A = 10^{-2}$ kg m^{-3}, $r_c = 10^6\ m$, $M = M_{\odot}$, and m equals the mass of the proton. It seems that for $0 < \mu < 1$, the self-consistent Eddington number is $1.35 < \varepsilon < 3.57$ if $A = -1$, and $3.25 < \varepsilon < 6.83$ if $A = -1.25$. Further exploration of equation (14) indicates that for reasonable γ, ε is typically rather less than 5.

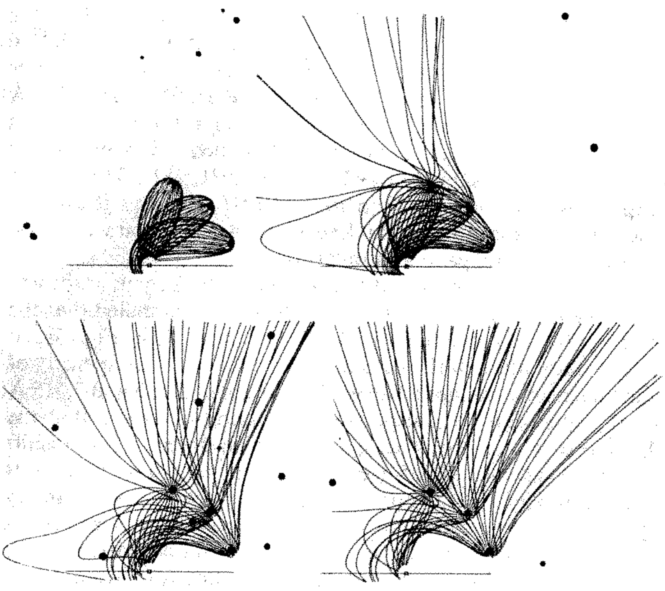

Fig. 3 Orbits of particles in the near force field of equation (1). The particles were radiated isotropically in the plane of the drawing with initial velocity 0.25 (normalisation as in Fig. 1), starting one disk radius away from the central object. Eddington numbers are 2, 3, 4, and 5, respectively. Note that even near the disk, beaming is rapidly established. The % of particles blown away is, respectively: 0, 18, 47, 70. These high values suggest a self-regulatory mechanism for the disk luminosity, by non-acceptance of infalling material when $\varepsilon \gtrsim 2.5$. Since strong beaming occurs for low ε only, this regulation indirectly helps to maintain the collimated outflow.

Apparently it is possible to establish strong beaming within a distance of the order of the disk radius. Thus X-ray sources with double radio structure[2,3] and extragalactic radio doubles could in principle derive their shape from an asymmetry of their central radiation field. A proper treatment of this asymmetric acceleration, however, will have to deal with radiative transfer[1] and must include considerations about the spectrum of the disk radiation, Rayleigh-Taylor instability of the accelerated material (which perhaps gives rise to clouds in the first place), and possibly the influence of magnetic fields. The problems involved are too extensive to be readily estimated, but probably the beaming will persist even when some radiation scattering is present. The reason to expect this is that, to first order, the radiation removed from the anisotropic component of F by scattering through an optical thickness τ will emerge as isotropic radiation pressure, which counteracts the influence of gravity:

$$Fr^2/MG \approx 2\varepsilon e^{-\tau}\cos\theta + \varepsilon(1-e^{-\tau})-1 \qquad (15)$$

Near $\varepsilon = 1$, the value of θ where $F = 0$ (that is, the opening angle of the cone within which the force is directed outward) does not depend strongly on τ; for example if $\varepsilon = 1.5$, the opening angle increases from 70° at $\tau = 0$ to 90° at $\tau = 1.1$.

I thank Jim Bardeen for a discussion on the type of similarity solution presented above, which he arrived at independently in a rather different disk model. My work was supported financially by the European Space Agency, U.S. NSF and NASA.

Magnetic field amplification in interstellar collisionless shock waves

IT is commonly assumed that a simple compression of the magnetic field occurs in interstellar shock waves. Recent space observations of the Earth's bow shock show that turbulent amplification of the magnetic field can occur in a collisionless shock. I show here that radio observations of Tycho's supernova remnant indicate the presence of a shock wave with such magnetic field amplification.

A collisionless shock wave can be characterised by three parameters: the Mach number, M, or the Alfven Mach number, M_A; the preshock ratio of thermal to magnetic pressure, β; and the angle between the flow direction and the magnetic field, θ (compare with ref. 1). Formisano and Hedgecock[2] classified the structures of the Earth's bow shock as a function of these parameters. They found that in shocks with $M_A > 3$, the degree of turbulence increased with β. The dividing line between laminar and turbulent flow occurred at $\beta \sim 0.1$. A series of observations of high β bow shock structures have been reported by Formisano *et al.*[3], who found magnetic field increases in the shocks which were much larger than normal. Typical field increases are by a factor of 2–4, but here increases by a factor of 20 or more were noted. In fact, in the first shock ($\beta = 8.0$, $M = 6.5$), the energy density in the postshock field was about equal to the dynamic pressure of the upstream solar wind; in the second ($\beta = 170$, $M = 7.4$), it was $\sim 15\%$ of the wind pressure, and in the third ($\beta = 49$, $M = 7.3$), it was $\sim 30\%$ of the wind pressure. There is at present no theory for the macroinstabilities which give rise to the turbulent amplification of the magnetic field.

Despite the lack of theoretical understanding, the possibility of field amplification in interstellar shock waves should be considered. In Tycho's supernova remnant, there is evidence for the presence of a collisionless shock. M and β of a shock are

$$M = 7.1\,(V_s/100\ \mathrm{km\ s^{-1}})\,(T/10^4\ \mathrm{K})^{1/2}$$

$$\beta = 3.9\,(T/10^4\ \mathrm{K})\,(n/1\ \mathrm{cm^{-3}})\,(B/3\times10^{-6}\ \mathrm{G})^{-2}$$

where V_s is the shock velocity and T, n, and B refer to the temperature, density, and magnetic field of the ambient medium which is assumed to be ionised. M_A is proportional to $M\beta^{1/2}$. The distance to Tycho's remnant is uncertain; distance dependent quantities will be be given in terms of D_6, which is in units of 6 kpc (refs 4, 5). Motions of the optical filaments in Tycho's remnant imply a velocity of 6200 D_6 km s^{-1} (ref. 6). The filaments appear along the outer edge of the radio emission (J. R. Dickel, personal communication), so they probably outline the shock front. In many places, the outer edge of the radio emission is unresolved at 6 arc s resolution[7], again providing evidence that this defines the shock front. The Coulomb mean free path of the hot postshock gas is a significant fraction of the radius of the remnant, indicating that collisionless heating of the gas occurs. The Mach number is larger than 100, which is greater than the Mach number of observed shock waves in the Solar System. There is no reason to expect a collisionless shock to become less turbulent with increasing M.

The height of Tycho's remnant above the galactic plane is 160 D_6 pc. The density and magnetic field are not well known at this altitude, but it is likely that $\beta > 1$. X-ray observations of the remnant indicate a high ambient density, $n \sim 4\ \mathrm{cm^{-3}}$ (ref. 8). Stability of the gas to the Rayleigh–Taylor instability in the galactic gravitational field may also require $\beta > 1$. Thus, on the basis of observations of the Earth's bow shock, it is expected that turbulent magnetic field amplification occurs in the shock wave of Tycho's remnant.

This hypothesis is supported by the radio observations of the remnant. Van den Bergh[6] found evidence from the filament motions that the remnant is in the adiabatic blast wave phase of evolution. The postshock flow can be described by a similarity solution. Duin and Strom[7] found that the observed radio polarisation, which implies a radial orientation of the magnetic field, could be quantitatively accounted for by the similarity solution because of the radial stretching in the postshock flow. This model is, however, viable only if the magnetic field is randomised in the shock wave. If only tangential compression occurred in the shock, a very particular magnetic field alignment would be necessary to give the observed polarisation direction. Because a radial field is implied by observations of several young remnants, this is unlikely. Thus, we have evidence that the magnetic field has been randomised in a turbulent collisionless shock.

Next, we consider to what extent the magnetic field is amplified in the shock wave on the basis of the nonthermal radio flux. First assume that there is no turbulent field amplification. The postshock magnetic field is probably less than 1.2×10^{-5} G because the ambient field is likely to be smaller than 3×10^{-6} G. If this field occupies 25% of the supernova remnant volume, the magnetic energy is $5\times10^{46}\,D_6{}^3$ erg. In order to produce the observed nonthermal radio radiation, a relativistic electron energy of $2\times10^{49}\,D_6{}^2$ erg is required. This is an extreme lower limit to the relativistic particle energy because it assumes that the magnetic field 160 D_6 pc from the galactic plane is the same as that in the plane, that the maximum field compression occurs in the shock, and that there is negligible energy in relativistic protons; the implied energy may actually be an order of magnitude higher. As the total energy release in the supernova is probably less than 10^{51} erg, this is a large fraction of the supernova energy. It is unlikely that such a high acceleration efficiency can be achieved, especially because adiabatic deceleration would be the main process acting on the particles in the absence of turbulence. On the assumption that there is no energy in relativistic protons, the equipartition field in Tycho's remnant is $6\times10^{-5}\,D_6{}^{-2/7}$ G, which would be accompanied by a particle energy of $2\times10^{48}\,D_6{}^{17/7}$ erg. The corresponding magnetic field pressure is only $0.02n^{-1}\,D_6{}^{-18/7}$ % of the dynamic shock wave pressure. The required increase in the magnetic field, a factor of about 20, is comparable to that observed in high-β bow shocks. It is likely that the magnetic field has been turbulently amplified in the collisionless shock wave.

The turbulent hydromagnetic motions may result in stochastic particle acceleration. Energetic particles are frequently observed in association with collisionless shocks in the Solar System. This subject is important in considering the radio emission from supernova remnants in the adiabatic phase of their evolution. The possible presence of turbulent collisionless shocks should also be considered in models of active galactic nuclei and double lobe radio sources.

I thank Dr E. Greenstadt for informative correspondence.

Lack of dust in quasar absorption line systems

THE origin of the absorption line systems in quasars is still uncertain[1]. Most such systems apparently have column densities of atomic hydrogen of the order of 10^{19} cm^{-2}, but, at least two quasars, 1331+170 (ref. 2) and PHL 957 (ref. 3), have such strong Lyman α absorption lines that atomic hydrogen column densities of the order of 10^{21} cm^{-2} are indicated. It should be possible to observe the dust produced 2,200 Å extinction bump as it is redshifted into the visible[4], and to determine whether the absorption line systems are produced in spiral galaxies where the dust content is similar to that in the interstellar medium. McKee and Petrosian[4] argue that the emission line regions of quasars generally lack dust, and that toward PHL 957 the 2,200 Å feature is absent. From recent published data, I argue that dust similar to that found in the interstellar medium is not found toward the quasars 1331+170 and PHL 957. This could explain why H_2 is not found toward PHL 957, and it also indicates that the absorption line systems in quasars are not produced in spiral galaxies similar to ours.

Carswell *et al.*[2] measured the profile of the Lyman α absorption line toward 1331+170, from which they estimated that the line centre is redshifted to 3,370 Å. From their Fig. 3*a*, it seems that although the data are noisy, the residual intensity of the line profile reaches a value of 0.5 at about 3,335 and 3,415 Å to the blue and red, respectively. It therefore seems that the Lyman α line centre is at 3,375 Å, which agrees with redshift system A at $z = 1.7755$ (refs 2, 5). There is also a redshift system at $z = 1.7852$, but in general the equivalent widths in system B are smaller than the equivalent widths in system A (ref. 2). It is likely that most of the hydrogen toward 1331+170 is in system A. In any case, the Lyman α line is so wide that it probably lies on the damping portion of the curve of growth, and the precise line centre does not affect the estimate of the atomic hydrogen column density, N(H). (Observations with higher signal-to-noise should be obtained to be certain that the Lyman α profile can be represented by damping wings). The Lyman α half width at half maximum (HWHM) is 40 Å. In the rest frame of the absorption line system, the HWHM is 14 Å, and N(H) equals 3×10^{21} cm^{-2} (ref. 6).

In our Galaxy, the dust-to-gas ratio is generally uniform to within a factor of two (ref. 7). We adopt $E(B\text{-}V)/N(\mathrm{H}) = 0.2\times10^{-21}$ mag cm^{-2} (refs 8, 9). Assuming a ratio of total to selective extinction of $R = 3.3$ (ref. 10) and taking the standard extinction curve for the 2,200 Å bump of Bless and Savage[11], then for representative wavelengths the dust optical depth may be written as $\tau(2{,}500) = 6.8\,E(B\text{-}V)$, $\tau(2{,}170) = 9.3E(B\text{-}V)$ and $\tau(2{,}000) = 8.2\,E(B\text{-}V)$. In all stars with sufficiently great reddening for the extinction to be measured accurately, this bump is present with a strength within a factor of two of its average values[12].

If $N(\mathrm{H}) = 3\times10^{21}$ cm^{-2} toward 1331+170 and if the dust-to-gas ratio in the absorption line system is similar to that in the interstellar medium, we would expect that $E(B\text{-}V) = 0.6$, and would expect to observe dust optical depths at 6,940, 6,020 and 5,550 Å of 4.1, 5.6 and 4.9, respectively. If lines are ignored, the flux density between 5,550 and 6,940 Å is observed to be constant to within a factor of 1.2 (ref. 5). If the dust-to-gas ratio were normal and assuming a flat spectrum, we would expect flux densities at 6,020, 5,550 and 6,940 Å to be in the ratios 1:2:4. Although a more precise analysis is possible, it seems that the dust-to-gas ratio toward 1331+170 is at least a factor of 20 less than in the interstellar medium.

From the measured equivalent widths[2] of the Fe II and Si II lines in the $z = 1.7755$ system, we find that even if these lines lie on the linear portion of the curve of growth, these species have column densities on the order of 3×10^{14} cm^{-2}. Therefore the gas phase abundances of the refractory elements iron and silicon toward 1331+170 is comparable to the gas phase abundances of the same species toward ζ Oph (ref. 13). There is no reason to suppose that the lack of dust toward 1331+170 results from a lack of metals.

The column density of atomic hydrogen toward PHL 957 is $7.5\pm2.5\times10^{20}$ cm^{-2} (ref. 14). Except for a very broad C III line, between 6,000 and 9,000 Å the flux density seems to be a power law within a factor of 1.2 (ref. 14). In the absorption line system at $z = 2.3088$, we would expect a flux density variation between 7,180 and 8,270 Å (corresponding to 2,170 and 2,500 Å in the rest frame) of a factor of about 1.5. It therefore seems that there is a lack of normal dust toward PHL 957 by at least a factor of two, in rough agreement with McKee and Petrosian's estimate[4].

I conclude that the absorption line region toward 1331+170 and probably the region toward PHL 957 are lacking dust similar to that in our own Galaxy. This can explain the lack of H_2 in these systems[14,15]. The column density of atomic hydrogen toward 1331+170 is so high, however, that it is unlikely that we are observing this quasar through a galactic halo[16] where the dust content might be unusually low. In the disk of a spiral galaxy, we would expect the dust/gas ratio to be comparable to the value in the interstellar medium, and it seems unlike that the absorption line system at $z = 1.7755$ toward 1331+170 is produced in a spiral galaxy similar to ours.

I thank Drs C. McKee and D. Richstone for their comments. This work was supported by the US NSF.

Relationship between atmospheric electricity and microwave radio propagation

ABRUPT changes in received polarisation coincident with lightning strokes have been seen on a 20 GHz satellite-to-earth radio link. These effects, and the surprisingly high levels of atmospheric cross polarisation observed on satellite links, have been tentatively attributed to high altitude ice crystals and their possible alignment by electric fields[1,2]. In this paper we shall add to the existing data by presenting a precise measurement of the time scale of the abrupt polarisation changes and an event showing a striking correlation between the electric potential gradient at the ground and the cross-polarisation of signals received from the satellite. This is believed to be the first time that direct measurements of atmospheric electric fields have been related to microwave propagation measurements.

The linearly polarised 20 GHz beacon signal from the NASA ATS-6 geostationary satellite was received at the Bradford University Oxenhope Laboratory during the period October 1975 to July 1976, while the satellite was stationed at longitude 35°E. At the receiving site (which is 450 m above sea level) the satellite was visible at 20° elevation with a 23° polarisation counter-clockwise from the vertical. Both the 'copolarised' and the orthogonal (or 'cross-polarised') received signals were measured. Without atmospheric hydrometeors present on the radio path, the cross-polarised component was typically >35 dB below the co-polarised component. A co-sited range-gated radar provided a quantitative measurement of reflectivity along the satellite radio path[1].

It is now apparent that the cross-polarisation measured on a microwave or millimetre wave satellite radio path can be an order of magnitude greater than that experienced on a terrestrial link for the same attenuation[1–3]. The cross polarisation measured on a terrestrial path agrees with that predicted from a rainfall model assuming anisotropy to arise from non-spherical raindrops[3,4], whereas small, high altitude ice particles (possibly needles or plates) can cause significant cross-polarisation on a satellite path[1,2,5,6]. This high-cross polarisation, not related to attenuation, as observed on satellite radio paths has been termed 'anomalous' although this description may be questioned.

During 1,050 h of measurements with ATS-6 (in discrete sessions of typically 4 h per d) nine separate 'anomalous' events were recorded (that is, events involving separate weather structures). Typically, as a rainstorm moved over the receiving site, high (anomalous) cross-polarisation, varying on a time scale of minutes, was observed at such times when the slant radio path intercepted the frozen particles in the storm structure[1]. In addition, during a thunderstorm on 7 May, 1976, abrupt changes in cross polarisation were observed (Fig. 1), in which the cross-polarised signal increased suddenly by several dB relative to the copolar level, and then returned close to the value before discharge in ~45 s. Of the twenty abrupt changes recorded during this event, four coincided with lightning strokes, as noted by observers on site for a short period of the storm. The other abrupt changes in cross-polarisation may also have been associated with lightning.

The rise times of the 15 largest abrupt cross-polarisation changes were found to be between 0.1 and 0.25 s, from FM tape recordings taken in a 500 Hz bandwidth. Sixteen of the abrupt changes showed a rapid rise in cross-polarisation, whereas the remaining four were decreases. These changes are self evidently not 'sferics' (in view of the relatively long decay times) and were only seen in the one event during ATS-6 sessions which showed pronounced lightning activity. Identical changes were observed with two independent, coherent receivers for the cross-polarised signals and furthermore, no abrupt changes were seen in the co-polarised signal.

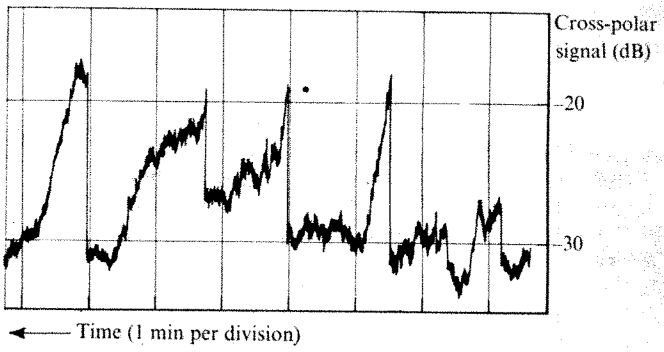

Fig. 1 Abrupt changes in cross-polarisation during a thunderstorm.

Following the observation of changes in cross-polarisation coincident with lightning strokes, a point-discharge electric field probe[7] and a photoelectric lightning detector were installed on site. The fine wire electrode of the field probe was 4 m above ground. Although no further lightning activity was recorded during satellite sessions, a strong correlation between anomalous cross-polarisation and point-discharge current was observed in three subsequent events, one of which, with a predominantly positive discharge current, is shown in Fig. 2. It is interesting to note that there is a better correlation between the probe current and cross-polarisation than between the co- and cross-polarised signals. In the other two events, a pronounced correlation between electric field on site and satellite path cross polarisation has been seen to occur with a time displacement.

To summarise, we have observed a pronounced correlation between electric field strength (measured near the ground) and cross-polarisation on a satellite radio path. Radar returns from high altitude (>3 km) particles, coincident with the appearance of high cross-polarisation, point

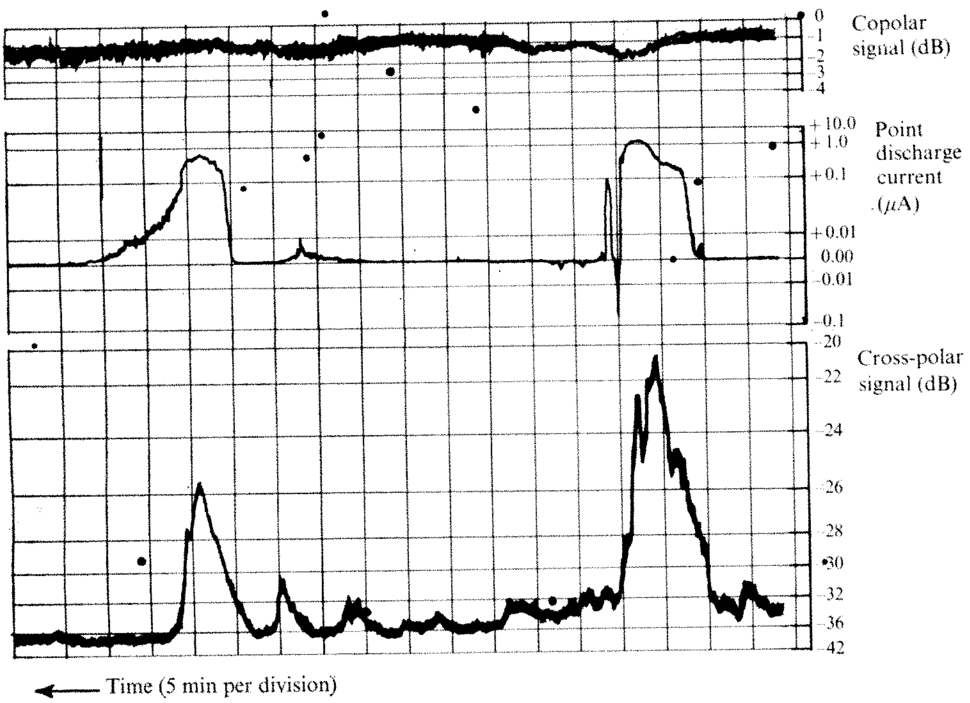

Fig. 2 Anomalous cross-polarisation and point-discharge current. Using an expression by Chalmers[7] the electric potential gradient, derived from the point-discharge current, is estimated at a maximum of 5 kV m^{-1} for the first peak and 1.7 kV m^{-1} for the second peak.

to ice particles as the cause for such cross-polarisation[1,2]. Analysis of the scattering from spheroidal ice particles[5,6] shows that high cross-polarisation can occur with small particles for low signal attenuation, provided that some degree of particle orientation is present.

Hendry and McCormick[8] have recently reported a high degree of orientation of ice particles from dual circularly polarised radar observations, which they have explained in terms of particle alignment in an electric field. 10^5 V m^{-1} has been shown to provide sufficient torque for rapid ($\sim$0.1 s) orientation of small ice spheroids[8].

We also interpret our results in terms of the orientation of small ice particles (1 mm or less) in the electric fields associated with convective storms. We emphasise that a degree of particle orientation does not necessarily imply a high degree of instantaneous alignment. Without significant damping forces imposition of an electric field on a randomly orientated group of ice needles or plates will produce simple harmonic motion around a preferred (average) orientation. The depolarisation from ice needles or plates[6] is such that only a small degree of preferred orientation is necessary for cross-polarisation.

In certain regions of storms aerodynamic turbulence will tend to disrupt field alignment, however it seems that in the upper regions of storm structures (typically $>$5 km in summer) turbulence is sufficiently low to permit a high degree of orientation[8]. Also the rapidity of alignment for small particles in strong fields, should permit realignment in the presence of turbulence provided that the latter is not overwhelming.

Alignment under aerodynamic forces alone is conceivable, but this does not explain the rapid lightning-correlated rises in cross-polarisation or the correlation between electric field and cross-polarisation.

The abrupt increases in cross-polarisation that we have observed may be interpreted in terms of the redistribution of charge in a thunderstorm at the incidence of a lightning stroke, resulting in a change in particle orientation. We emphasise that for linear polarisation a change in particle orientation with respect to the polarisation plane of the incident wave could result in either an increase or decrease in cross-polarisation, but a measurement with circular polarisation would show cross-polarisation related directly to the degree of particle orientation. Since coherent receivers were used for extraction of our cross-polarised signals (phase locked to the copolar signal), explanation of the abrupt cross-polarisation changes in terms of incoherent emissions from ionisation or lightning flashes is not credible.

If the rapid, lightning-correlated cross-polarisation changes that we have observed are caused by particle reorientation then we must conclude, from the observed orientation times, that small particles are responsible. Small particles are also inferred from the absence of significant attenuation during anomalous cross-polarisation[5,6].

The precise nature of electric fields in thunderstorms is a matter of current debate[9] and we hesitate to be dogmatic about the model applicable to our observations. Measurements of satellite cross-polarisation with circular polarisation would help clarify this issue. Apart from the implications of our results for the communications engineer, we would expect our results to be of relevance to the understanding of thunderstorm models.

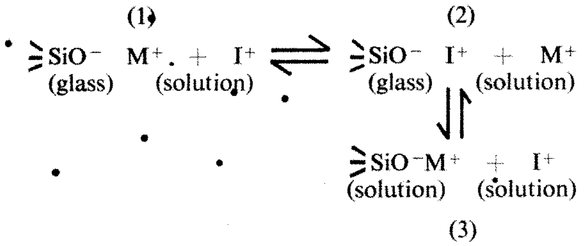
Decomposition of silicate glasses in alkaline solutions

WHEN a silicate glass comes into contact with a neutral or a slightly alkaline aqueous solution the only reaction which occurs is a diffusion controlled hydrogen–alkali ion exchange. The silica network is stable. In solutions with $pH >$ about 9, the network starts to break down at its interface with the solution. The rate of breakdown increases sharply with increasing pH; simultaneously the ion exchange rate decreases sharply. In solutions with $pH >$ about 12 it is difficult to detect the alkali released in solution by classical microanalytical methods as the solution is primarily made up of alkali hydroxide. It has been repeatedly suggested that the ion exchange reaction ceases to occur under these conditions and that the decomposition process becomes only a network breakdown. Surface and in-depth concentrations of alkalis in a glass which has been subjected to a highly alkaline solution have been determined by Auger electron spectroscopy (AES). Our results indicate that the ion exchange does not cease to occur in highly alkaline solutions as commonly believed.

The decomposition may be represented by the following scheme:



$$\begin{tikzcd}[column sep=small]
\underset{\text{(glass)}}{\geqslant\text{SiO}^-\ \text{M}^+} + \underset{\text{(solution)}}{\text{I}^+}\ \text{(1)} \arrow[r, shift left] & \arrow[l, shift left] \underset{\text{(glass)}}{\geqslant\text{SiO}^-\ \text{I}^+} + \underset{\text{(solution)}}{\text{M}^+}\ \text{(2)} \arrow[d, shift left] \\
 & \arrow[u, shift left] \underset{\text{(solution)}}{\geqslant\text{SiO}^-\text{M}^+} + \underset{\text{(solution)}}{\text{I}^+}\ \text{(3)}
\end{tikzcd}$$

where M denotes an alkali atom, usually sodium, while I denotes a solvated monovalent cation, usually a proton. This reaction scheme is widely used in discussing the physicochemical processes (corrosion, membrane potentials, electrokinetic phenomena, etc.) exhibited by glass and by many silicates.

The scheme often appears as two separate equations relating (1) ⇌ (2) and (2) ⇌ (3). Ion exchange processes which take place in aqueous solutions and involve a solvated proton as a reacting species are essentially acid–base reactions. Reactions (1) ⇌ (2) and (2) ⇌ (3) are related through the equilibrium constants of the conjugate

$$\geqslant\text{SiOH}/\geqslant\text{SiO}^-$$

acid–base pair[1] by the relation $K_aK_b = K_w = 10^{-14}$ at 25 °C, K_a being of the order 10^{-10}, $K_b \sim 10^{-4}$.

In alkaline solutions where $a_{M^+} \geqslant a_{OH^-} \gg a_{H^+}$ a shift of the equilibrium towards positions (2) and (3) is favoured. The reverse occurs in acidic solutions. Studies on the kinetics of approach to the equilibrium of reaction (1) → (2) and (2) → (3) have been carried out in aqueous solutions buffered at pH values of 1–13. For pH of 1–9 the rate of dealkalisation remained constant, and independent of the pH of the solution, and sharply decreased with increasing pH thereafter. The rate of breakdown was extremely low in the pH range 1–9 and sharply increased with pH above the critical value of about 9 (ref. 1).

Chemical analysis of alkalis and silica in the glass and in solution, at various pH values, shows that the ratio M_2O/S_iO_2 is always higher in acidic, neutral and slightly alkaline solutions than in the glass. This is considered[1] to imply that reaction (2) → (3) lags behind reaction (1) → (2) and a silica-rich leached layer is developed on the glass surface in contact with the solution. The existence of such a layer has been proved[2] by the establishment of in-depth composition profiles of glasses which have been in contact with aqueous solutions of varying pH.

As the pH of the solution increases above 9, the M_2O/SiO_2 ratio in the solution slightly decreases and tends to approach the same value as in the glass. Hence, it has been inferred[3–6] that the decomposition of glass becomes entirely a dissolution process, that is, a network breakdown as represented by reaction (2) → (3). This inference is tempting, because it appears difficult for a solvated alkali ion in solution to re-enter the glass by reaction (2) → (1) to occupy a site originally filled by an anhydrous alkali ion. The almost linear rate of decomposition of glass in highly alkaline solutions has been considered to support such inference, but concrete evidence is lacking. Analytical solution chemistry is little value for deciding whether reaction (2) → (3) goes faster than reaction (2) → (1) or continues to lag behind it because one would have to detect parts per million of the alkali species originally present in the glass in the presence of much higher concentration of the other alkali species which is used for buffering the medium. We have devised the following experiment to decide whether the breakdown of glass represented by reaction (2) → (3) supersedes the ion exchange reaction (2) → (1) under the extreme condition where $a_{M^+} > a_{OH^-} \gg a_{H^+}$. Two identical fresh rectangular samples were prepared by breaking down a commercial soda-lime–silica glass container which has not been subjected to any surface treatment. The approximate composition in weight per cent of the glass was as follows: 74% SiO_2, 13% Na_2O, 12% ($MgO+CaO$) and 1% other oxides. The first sample was immersed in a solution of 0.1 M NaOH; the second in a solution of 0.1 M NaOH+1.0 M Li_2CO_3. Each sample was allowed to remain in contact with the solution for 5 h at 25 °C. Lithium was chosen as a tagging cation as the free energy change of its association with the $\rightarrow SiO^-$ sites makes it more favourable to other alkalis[5]. If reaction (2) → (3) proceeds faster than reaction (2) → (1), lithium could not be detected on the treated glass surface, and complete dissolution of the glass in highly alkaline solutions, already inferred by many workers, would become evident. If, on the other hand, Li^+, not in association with carbon, from the CO_3^{2-} radical, with which it must be at least partly associated in solution, could be detected in the glass to

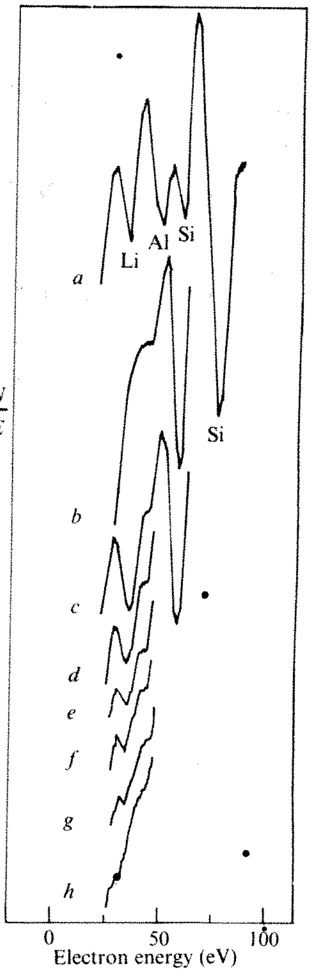


Fig. 1 Auger electron spectra for (*a*) Spodumene fracture surface (*b*) Soda-lime–silica glass surface treated in 0.1 NaOH (*c*) Soda-lime–silica glass treated in 0.1 N NaOH+1.0 N Li_2CO_3. (*d–h*) Sample *c* after bombardment with a 2.0 keV beam of argon ions for 0.5, 2.0, 6.0, 10.0 and 18.0 min, respectively. some depth, this would indicate a decomposition process in which the ion exchange reaction still has a role.

$$\underset{\text{(glass)}}{\geq\text{SiO}^-\text{Na}^+} + \underset{\text{(solution)}}{\text{Li}^+} \rightleftharpoons \underset{\text{(glass)}}{\geq\text{SiO}^-\text{Li}^+} + \underset{\text{(solution)}}{\text{Na}^+}$$

AES was performed on the two glass samples treated in the manner outlined above. The technique used was that described by Pantano *et al.*[2] for glass surfaces. It involves cooling the samples to liquid nitrogen temperature, maintaining the beam current density at low value and minimising the electron irradiation time. Approximate surface and in-depth concentration of alkalis were determined from the spectra using an Ar ion-milling apparatus to remove surface material while simultaneously analysing with AES. The change in the Auger peak-to-peak height of each species is generally assumed to be proportional to the change in concentration of that constituent. Figure 1 shows the spectra obtained.

The spectra of a spodumene ($Li_2O.Al_2O_3.4SiO_2$) fracture surface was obtained as a standard, because of the difficulty of identifying the Auger transition for Li (Fig. 1*a*). The peak energy for the Auger transition assigned to Li is 37 eV, while the main Si peak appears at the 76 eV with a minor peak at 58 eV, and the Al peak appears at 51 eV. In Fig. 1*b* the only Auger transition in this energy range is due to Si (58 eV). The main silicon peak at 78 eV is not shown. In Fig. 1*c* in addition to Si, the peak identified as being due to an Li Auger transition is also detected. In Fig. 1*d*–*h*, the persistence of a Li signal for up to 10 min of ion milling (~ 250 Å) suggests the existence of Li within the glass surface. Also, the sodium peak intensity of the surface treated with $NaOH+Li_2CO_3$ was approximately 40% less than that measured on the glass treated without Li. This is a reasonable result as the sites now occupied by Li would otherwise be occupied by Na. These results lead us to exclude complete dissolution, or glass network breakdown, as a possible mechanism for glass decomposition in these solutions and conclude that the ion exchange continues to have an important role even in highly alkaline solutions.

Ceramic materials and more than two thirds of the rocks constituting the Earth's crust are basically made of the same building unit as glass, that is, the silicon–oxygen tetrahedron, and consequently undergo the same sequence of reactions with aqueous solutions. The present conclusion possibly applies to other silica-based materials.

We thank Professors R. W. Douglas and L. L. Hench for useful comments on the manuscript.

A near perfect shape-memory ceramic material

After high temperature plastic deformation and cooling under load to room temperature, glass-ceramics containing mica as the principal crystalline phase retain a near-perfect memory of their undeformed state, the plastic strain being recoverable by a subsequent high temperature anneal. Activation energy measurements support the hypothesis that dislocations in the mica crystals control the shape-memory process.

The elastic martensitic transformations responsible for shape-memory phenomena in certain metal alloys have been the subject of extensive research, recently reviewed by Wayman[1]. In principle, any multi-phase system containing phases with different viscosities (but equal shear moduli) can also exhibit shape-memory behaviour since elastically strained components are capable of driving viscous elements back towards their original undeformed shapes. Such behaviour, by internally oxidised copper, has been demonstrated by Brown and Stobbs[2].

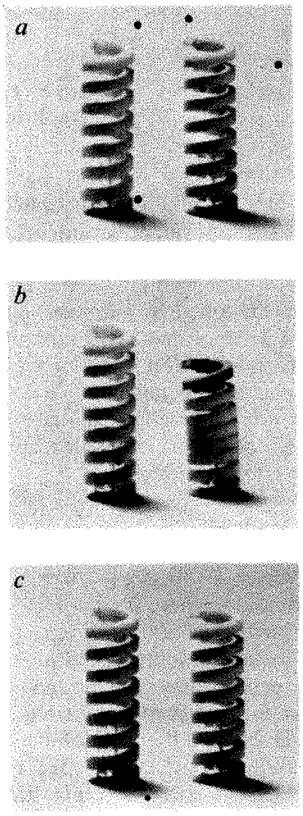

Fig. 1 The shape-memory behaviour of a mica glass-ceramic. The specimen on the right has been subjected to high temperature compression before unloading at room temperature (*b*) and then annealed at high temperature (*c*).

At temperatures >300 °C, mica can be deformed plastically by slip between its basal layers. Such deformation in crystals intimately mixed with a rigid, multiply connected phase should permit retention at room temperature of any small shape change imposed on the phase mixture at temperatures above 300 °C; since glide in mica is not possible at low temperature, removal of the mechanical constraint, after cooling to room temperature, is not accompanied by the reversal of plastic strains in the mica that would be required in order to release fully the elastic strain in the matrix. The elastic strain energy thus stored provides a driving force for recovering the undeformed shape, should the temperature subsequently approach 300 °C. If the micaceous phase is singly connected, no plastic strain can leak to the free surface and, in principle, the phase mixture should be capable of returning precisely to its original shape.

The series of mica glass-ceramics developed at Corning Glass Works[3] fit this specification for a perfect shape-memory solid. The volume fraction of fluorophlogopite, the

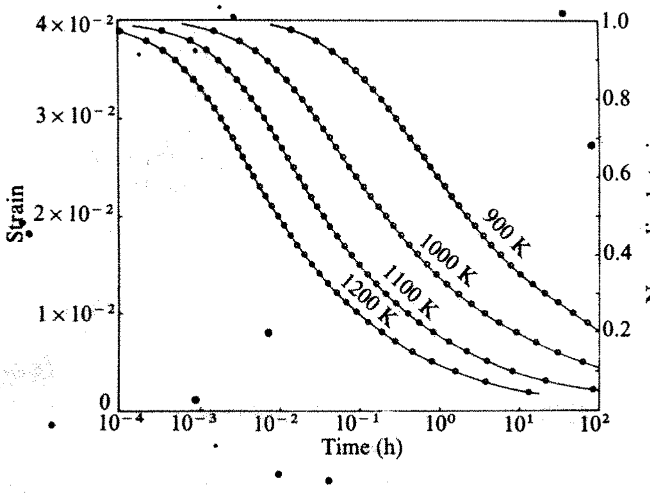

Fig. 2 Summary of torsional strain recovery data obtained from Corning 9650.

main crystalline phase, is typically 2/5 to 3/5, with maximum crystal diameters ranging from ¼ µm to 100 µm and aspect ratios of order 10 : 1. The mica glass-ceramics are easily machined using conventional tools, and helical specimens having outer diameter 2 cm and pitch 3.2 mm were cut from as-crystallised rods. Figure 1 shows two identical helical specimens machined from Corning code 9650, (*a*) before deformation, (*b*) after quickly cooling the specimen on the right from axial compression at 500 °C and (*c*) after subsequently annealing (*b*) for 2 h at 800 °C. Each individual pitch has recovered at least 87% of the imposed strain. In other preliminary experiments, recoveries of 99% after prolonged anneals have been attained.

Using improved specimens ultrasonically machined from Corning codes 9650 and 9658, accurate measurements of axial strain recovery have been made during annealing at several temperatures. The measurements have been converted to local torsional strain and Fig. 2 shows a summary of the data for Corning code 9650. Similar data was obtained for glass-ceramic code 9658. For each material, the data from all temperatures may be superposed on to a master curve at, say, 1,000 °C merely by shifting the individual curves horizontally. Assuming that a single mechanism is rate controlling, the shift corresponds to an activation energy of 42±5 kcal mol⁻¹ for Corning 9650, and 22±3 kcal mol⁻¹ for Corning 9658. These are much lower than the activation energies for large scale, high temperature creep of the same mica glass-ceramics. In the temperature range 480–670 °C, for example, Corning 9650 tested in tension creeps with an activation of 100 kcal mol⁻¹ (James and Ashbee[4]). The larger activation energy is characteristic of flow of the glassy matrix, whereas the activation energy for shape-memory behaviour is expected to be that for dislocation glide in mica. A measurement for the latter, obtained from the temperature/time dependence of the microhardness of muscovite shown in Fig. 3, is 29±4 kcal mol⁻¹.

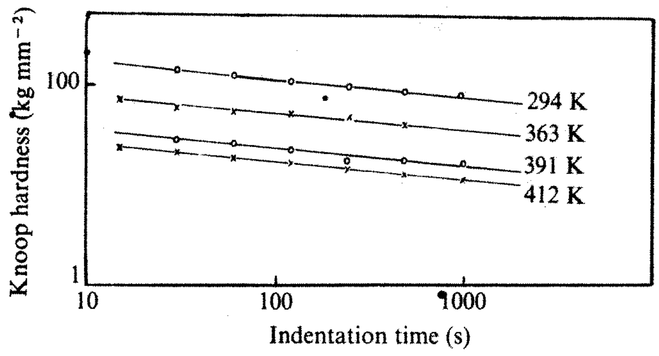

Fig. 3 Indentation creep of muscovite single crystals. (Long axis of Knoop indenter parallel to *a* axis.)

The use and misuse of pure water PVT properties for lake waters

ALTHOUGH dissolved substances affect the thermodynamic properties of lake waters,[1,2] many limnologists still consider lake water as pure water[3–8]. This can be a good assumption if used with caution: lake water is by no means pure water, especially when the precise pressure, volume, temperature (PVT) properties are considered. PVT properties of lake water can be determined from an equation of state for seawater provided that the total mass fraction of dissolved salts in seawater and lake water are equated[9]. In addition, the total mass fraction of dissolved salts affects calculations concerning the temperature of maximum density and thus stability[10]. Therefore, in the absence of direct PVT measurements on a particular lake, it is at present most appropriate to use an equation of state for seawater when examining effects of PVT properties in lakes. We present here a short equation of state determined with a precision of 2×10^{-6} g cm⁻³ in density over the appropriate range for most fresh water lakes, 0–0.6‰ salinity, 0–30 °C, and 0–180 bar. The equation of state is based on the 1 atm pure water density and compressibility equations of Kell[11], the pure water temperature and pressure effects of Fine and Millero[12], and the effects of dissolved salts of Millero *et al.*[13] and Chen and Millero[14]:

$$d^{\mathrm{P}} = d^0/(1-P/K) \tag{1}$$

$$\begin{aligned} d^0\,(\mathrm{g\,cm^{-3}}) = {} & 0.9998395+6.7914\times10^{-5}t \\ & -9.0894\times10^{-6}t^2+1.0171\times10^{-7}t^3 \\ & -1.2846\times10^{-9}t^4+1.1592\times10^{-11}t^5 \\ & -5.0125\times10^{-14}t^6+(8.221\times10^{-4} \\ & -3.87\times10^{-6}t+4.99\times10^{-8}t^2)\,S(‰) \end{aligned} \tag{2}$$

$$\begin{aligned} K(\mathrm{bar}) = {} & 19652.17+148.376t-2.329t^2 \\ & -1.3963\times10^{-2}t^3-5.90\times10^{-5}t^4 \\ & +(3.2918-1.719\times10^{-3}t+1.684\times10^{-4}t^2)P \\ & +(-0.8985+2.428\times10^{-2}t+1.114\times10^{-2}P)\,S(‰) \end{aligned} \tag{3}$$

where d^{P} and d^0 are the densities of lake water at applied pressures

P and 0 (sea level), respectively, t is the temperature in °C, $S(‰)$ is the salinity:

$$S(‰) = 0.9951437 g_T \quad (4)$$

where g_T is the total grams of dissolved salt in 1 kg of lake water[15]. The values of g_T usually increase with depth due to the increase of HCO_3^-, Ca^{2+} and nutrients[16]. The small changes in composition in a lake can be accounted for by making the appropriate changes in g_T. Further, Millero[9] and Millero *et al.*[17] showed that the densities calculated from the seawater equation of state for Lake Tanganyika water and artificial river water agree with the measured values to within $\pm 2 \times 10^{-6}$g cm^{-3} despite the large composition difference between the two waters. This verifies the validity of our equation of state for fresh waters.

One atmosphere densities computed from equation (1) at 0.15, 0.30, and 0.60‰ salinity over the temperature range of 0–30 °C are shown in Fig. 1. Also shown are the densities for pure water at 0 and 1.0 bar (gauge). It is clearly shown that even a nominal amount of salt, 0.15‰ salinity or 151 mg kg^{-1}, increases the density of pure water appreciably. At 0 °C, the increase in density is 123×10^{-6}g cm^{-3}, which is equivalent to a change of 2.4 bars in pressure or 2.9 °C in temperature. This increase in density has often been neglected and it is certainly not negligible.

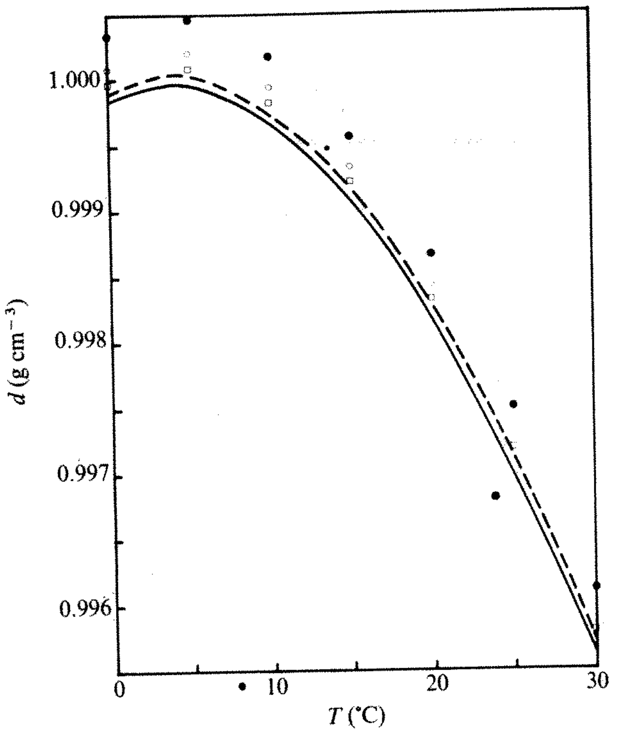

Fig. 1 Densities for pure water at 0 (———) and 1.0 (– – –) bar (gauge) and for lake waters at 0.15 ( ), 0.30 ( ) and 0.06 ( ) ‰ salinity at 0 bar (gauge) over 0–30 °C.

The existence of a temperature of maximum density, T_{MD}, is of fundamental importance in limnology. An equation is given to be used to estimate T_{MD} with a precision of 0.001 °C,

$$T_{MD} = 3.9839 - 1.9911 \times 10^{-2}P - 5.822 \times 10^{-6}P^2 - (0.2230 + 1.111 \times 10^{-4}P)S(‰) \quad (5)$$

At 1 atm, a nominal amount of salt, 150 mg kg^{-1}, in a freshwater lake contributes 0.033 °C to the depression of the temperature of maximum density. This seemingly small number, 0.033 °C, which corresponds to the effect of 16.8 m of water, is orders of magnitude larger than the precision of the *in situ* temperature measurements and certainly should not be neglected. We, therefore conclude that the salt content is of significance in freshwater lakes and our equation of state should be used to calculate reliable PVT properties for lake waters.

Raman scattering and the characterisation of atmospheric aerosol particles

AIRBORNE particulates have a major role in the air pollution problem. They are responsible for acid rain, reduced visibility, and, in certain size ranges, are deposited in the lungs where they can cause various disorders. Considerable effort has been expended in the analysis of these particulates using techniques such as wet chemistry, X-ray fluorescence, infrared spectroscopy and ESCA. Yet there are still great uncertainties as to the chemical form and origin of many of the particulate species. We describe here preliminary studies of the feasibility of characterising particulate pollutants by means of Raman spectroscopy. We believe that this is the first attempt to apply this spectroscopic technique in this area of research. The samples studied included diesel exhaust particles, automobile exhaust particles (unleaded fuel, no catalytic converter) and several ambient air samples. The spectra from these samples were compared with those of polycrystalline graphite and activated carbon which were used as references. Our results indicate that physical structures similar to activated carbon are at least a major species and may be the dominant species in both source-enriched and ambient samples. The implications of this observation could be quite important in terms of atmospheric chemistry, health effects, weather modifications and the effects of aerosols on the albedo.

The beam from a Coherent Radiation argon ion laser (operating with 1 W at 5145 Å) was focused by a 75-mm focal length cylindrical lens to a spot of 0.06 × 2 mm on the sample surface, and the backscattered radiation was collected and imaged by an f/3.4 lens on to the slit of a Jarrell Ashe double monochromator. The incident polarisation of the laser was perpendicular to the slit of the spectrometer, and the scattered polarisation was not analysed. The output of the spectrometer was detected by an FW130 photomultiplier cooled to −20 °C and used in a photon-counting mode. The photon pulses, after appropriate pulse shaping, were counted and displayed on a multichannel analyser. To minimise heating effects, the highly absorbing samples used in these experiments were rotated at 1800 r.p.m. by a motor—this increases the area illuminated by the laser beam by a large factor with almost no loss in signal level. The focal spot of the laser was located approximately 5 mm below the axis of rotation so that the effective illuminated area was an annulus of radius 5 mm and width 2 mm which yielded a rather low power density of ~ 1.5 W cm^{-2}.

The samples used in these experiments were EDM 3 grade polycrystalline graphite (POCO Graphite Inc.), Norit A activated carbon (Pfanstiehl Labs), diesel exhaust collected on a glass fibre filter, automobile exhaust collected on a glass fibre filter from a number of cold starts of a poorly tuned 1974 Ford Pinto (lead-free fuel; no catalytic converter), and an ambient samples collected in 1975 as part of EPA's RAPS programme in St. Louis, Missouri. The latter sample was collected on a 1.2-μm Millipore filter using a dichotomous sampler[1] and was in the small size range fraction. The diesel and car exhaust samples were removed from the filter and transferred to an aluminium flat. This technique allowed us to obtain excellent Raman spectra of the particulates without interference from the large fluorescence of the filter material. This technique could not be applied to the ambient samples because of insufficient loading, and therefore in this case the Raman spectrum was obtained directly from the particles on the Millipore filter substrate.

Figure 1 shows the Raman spectrum obtained from automobile exhaust. Similar spectra were observed for diesel exhaust, activated carbon, and polycrystalline graphite with the dominant features of the spectrum occurring at 1,200–1,700 cm^{-1}. For polycrystalline graphite a strong line is also observed at ~2,700 cm^{-1} which we associate with a C–H vibration. In the ambient sample, where the signal to noise is severely limited by the large fluorescence background, the only lines that were clearly seen above the noise level were also in the 1,200–1,700 cm^{-1} spectral region. Figure 2 shows the Raman spectrum for the various samples in this region.

Koenig *et al.*[2] measured the Raman spectrum of a single crystal of graphite as well as that of polycrystalline graphite and activated carbon. In a single crystal only the Raman mode near 1,600 cm^{-1} is observed, and from a group theoretical analysis, it has been assigned to the $k = 0$ E_{2g} phonons of the graphite lattice. The mode near 1,350 cm^{-1} appears only in samples which are not perfectly ordered, and its intensity relative to the one near 1,600 cm^{-1} varies inversely with the crystallite size, L_a, as obtained from X-ray data. Solin *et al.*[3] have shown that this ratio tends to saturate for crystallite sizes less than 40 Å. The identification of the 1,350 cm^{-1} mode is uncertain, but Koenig *et al.* suggest that it may be due to an A_{1g} phonon which is normally Raman inactive but is active in this case due to a breakdown of the k selection rules by the small crystallites in the sample.

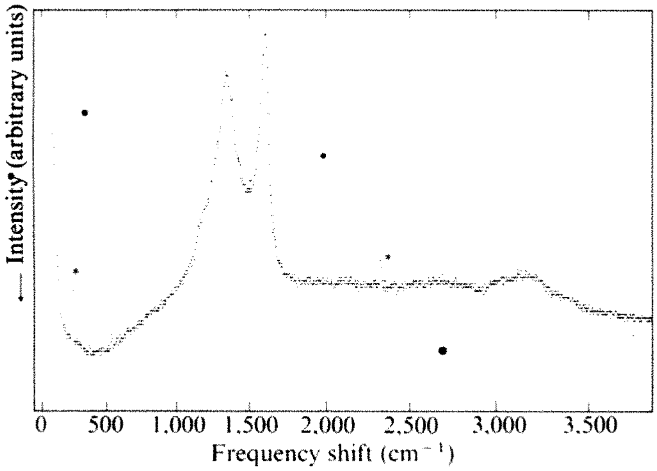

Fig. 1 Raman spectrum of automobile exhaust in the spectral region between 90 and 3,830 cm^{-1}. The slit width for this scan was 3 Å. The lines identified with an asterisk are due to grating ghosts.

It is evident from Fig. 2 that the spectra of activated carbon, diesel exhaust, automobile exhaust, and the ambient sample are very similar. The positions of the two Raman modes in these spectra are coincident to within ±10 cm^{-1} which is the estimated experimental error. Since the phonon frequencies are a sensitive probe of the lattice, we suggest that these spectra give strong evidence for the existence of physical structures similar to activated carbon in the samples we have studied. This is not surprising since activated carbon is also produced in a combustion process.

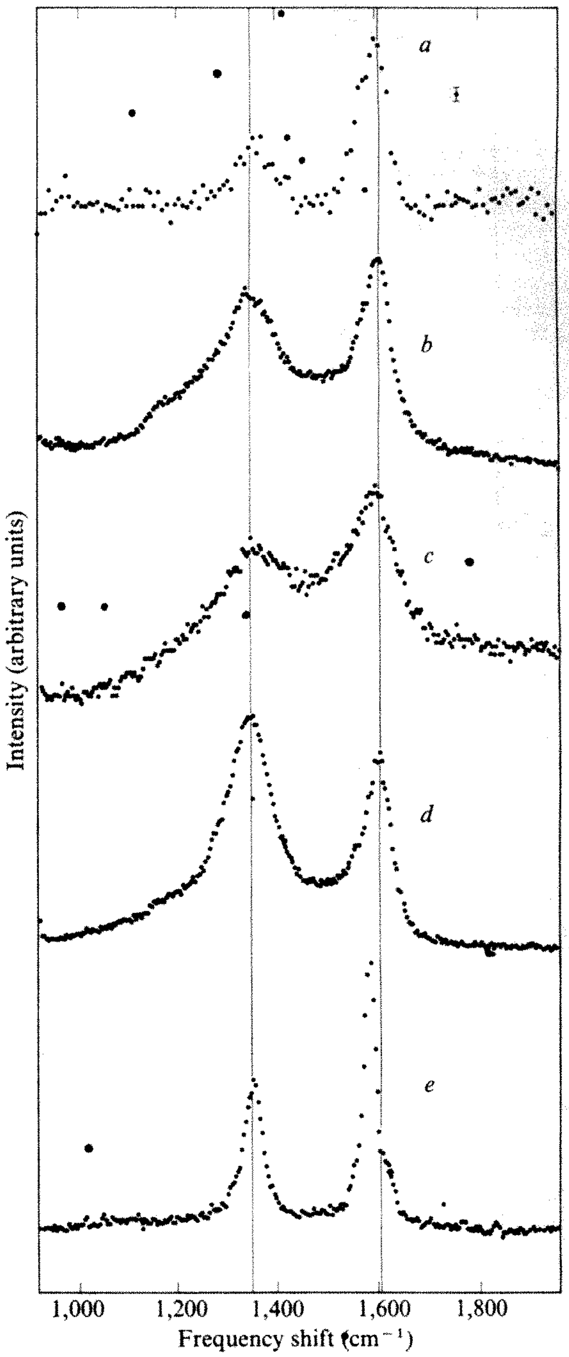

Fig. 2 Raman spectra between 1,200 and 1,700 cm^{-1} of *a*, ambient sample; *b*, automobile exhaust; *c*, diesel exhaust; *d*, activated carbon and *e*, polycrystalline graphite. The slit width for samples *b*–*e* was 3 Å; for sample *a*, 7-Å slits were used to improve signal to noise ratio.

We can estimate from literature data[2] the crystallite sizes in the various samples from the intensity ratios of the two observed Raman modes. The automobile exhaust and diesel exhaust samples have roughly the same peak intensity ratio, yielding crystallites of ≃ 50 Å in size, while the ambient sample seems to have crystallite sizes of ≃ 100 Å. We would expect such structures to have very large internal surface area.

Novakov *et al.*[4] have proposed that fine soot particles, which in many ways are similar to activated carbon, may have a major role in atmospheric chemistry. To assess the importance of the proposed soot-catalysed reactions, it is important to determine the chemically active primary carbon in the carbonaceous fraction of ambient and source-enriched aerosol particles. Our results indicate that physical structures similar to activated carbon are present in diesel exhaust, automobile exhaust and ambient samples. The fact that these features tend to dominate the Raman spectrum may indicate that graphitic 'soot' is the major species in the samples we have measured. But, the large intensity in these modes may be due just to their large Raman cross-section, and therefore a quantitative interpretation of these results will have to await a more detailed analysis. Such an analysis will have to include measurements of the Raman cross-section, optical absorption cross-section, and take into account the little-understood particle size effects[5].

Fluctuations of seismicity before major earthquakes

LONG-TERM precursory changes of seismicity previously reported are (1) a change in the relationship between earthquake frequency and magnitude, and (2) a decrease in the frequency of micro-earthquakes. In a review of earthquake precursors Rikitake[1] cites eleven examples of the former and three examples of the latter. On the dilatancy hypothesis a decrease in activity is to be expected from dilatancy hardening[2]; an earlier gradual increase of activity due to the secular increase of tectonic stress was also postulated[2]. A more distinctive sequence of seismicity fluctuations can be recognised from data in seismological bulletins. The fluctuations are large: a burst of activity marking the start of the precursory sequence is followed by a period of abnormal quiet, and this lasts until the onset of the major event. We report here characteristic changes of minor earthquake activity, preceding a number of recent major earthquakes in regions with good seismographic coverage, and suggesting a new basis for long-term prediction relying directly on the normal data output of permanent seismograph networks.

The initiating burst of activity differs markedly from the major event: the general level of magnitude is substantially lower, and no earthquake is much larger than the rest. Thus the term 'precursory swarm' is appropriate, for although earthquake swarms are commonly regarded as characterising regions of Quaternary volcanism it is the lack of a main shock that distinguishes a swarm from a typical tectonic event. The abnormally low activity with which the precursory sequence continues defines a seismic gap in both time and space; the geographic gap is of premonitory value since the major event (as well as the precursory swarm) occurs within it, though whether it is well delineated depends on the ambient level of seismicity and the accuracy of epicentre location.

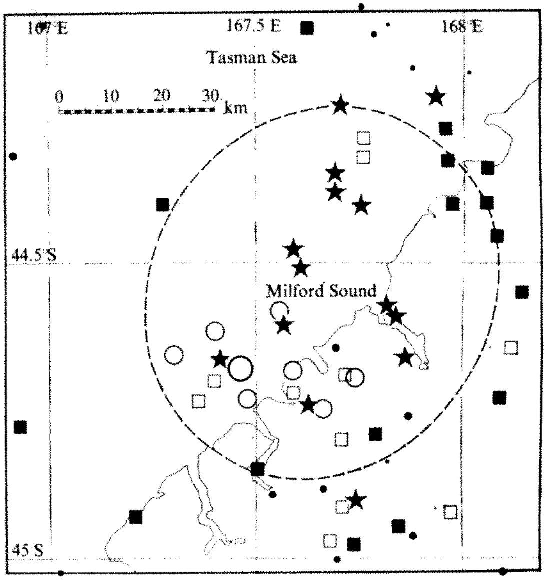

Fig. 1 Epicentre map of crustal earthquakes with $M_L \geqslant 4.6$, occurring from January 1961 to May 1976, and showing approximate boundary of precursory area for the Milford Sound earthquake of 4 May 1976, $M_L = 7.0$. The seismic episodes indicated are as follows: normal seismicity (□), 1 Jan. 1961–21 Feb. 1968; precursory swarm (★), 22 Feb. 1968–23 Dec. 1968; precursory gap (■), 24 Dec. 1968–3 May 1976; major event (○), 4 May 1976–8 May 1976.

The phenomenon is illustrated by two major earthquakes, one from New Zealand and the other from California. The Milford Sound earthquake of 4 May 1976, magnitude $M_L = 7.0$, is the largest New Zealand shock since 1968, although by virtue of its location offshore in Fiordland, a rugged and sparsely populated region, it attracted little public notice. The Ocotillo Wells earthquake of 9 April 1968, magnitude $M_L = 6.4$, was one of the two largest California earthquakes since 1954; it was widely felt and involved displacements along a 33-km segment of the Coyote Creek fault[3].

The Milford Sound earthquake data are taken from published bulletins[4], and from recent files made available by Dr R. D. Adams, Superintendent, Seismological Observatory, D.S.I.R., Wellington; the data for the Ocotillo Wells earthquake are taken from Hileman *et al.*[5].

For the relevant areas, Figs 1 and 2 show the epicentres of located earthquakes occurring in the specified time intervals

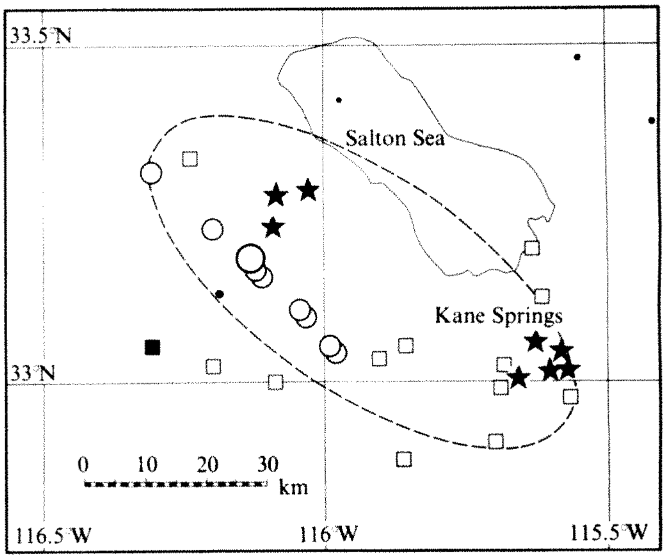

Fig. 2 Epicentre map showing approximate boundary of precursory area for the Ocotillo Wells earthquake of 9 April 1968, $M_L = 6.4$. All earthquakes with $M_L \geqslant 4.1$, occurring from January 1962 to April 1968 are shown. The seismic episodes indicated are as follows: normal seismicity (□), 1 July 1962–10 April 1965; precursory swarm (★), 11 April 1965–26 August 1965; precursory gap (■), 27 August 1965–8 April 1968; major event (○), 9 April 1968–16 April 1968.

and magnitude ranges. (The Milford Sound major event was crustal in origin and earthquakes originating below the crust have been excluded.) Four seismic episodes are distinguished: normal seismicity, the precursory swarm, the precursory gap and the major event.

The hypothesis that all the swarm and major-event epicentres and none of the gap epicentres lie within a certain area is satisfied by the elliptical boundaries shown in Figs 1 and 2; in the Milford Sound example allowance is made for location errors of up to 7 km, which is within the typical standard deviation for epicentre locations in the region. Of course, any actual boundary will not be precisely elliptical. It is of interest, however, that in each example the orientation of the ellipse is approximately parallel to the dominant tectonic trend in the region.

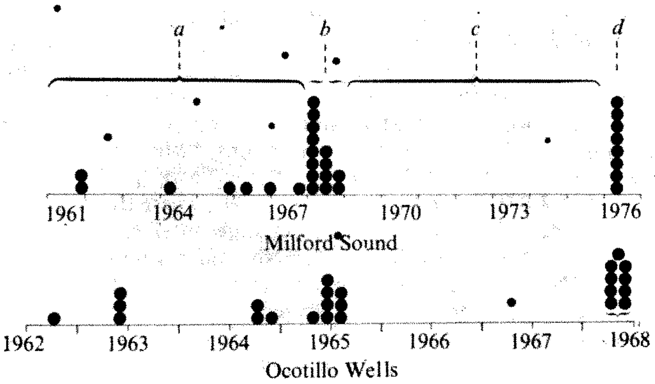

Fig. 3 Seismic sequences associated with the precursory areas of the Milford Sound and Ocotillo Wells earthquakes. The period of normal seismicity has been chosen about equal to that of the precursory gap, and the two time scales have been adjusted to facilitate comparison. *a*, Normal seismicity; *b*, precursory swarm; *c*, precursory gap; *d*, major event.

Thus the fluctuations of seismicity follow a simple geographic pattern. For the Ocotillo Wells sequence the precursory boundary encloses most of the normal seismicity and it is thus not surprising that the precursory gap episode is not represented by more epicentres.

The seismic sequences are plotted against time in Fig. 3, which shows how the seismicity within the precursory area fluctuates, in relation to the normal level, before a major event.

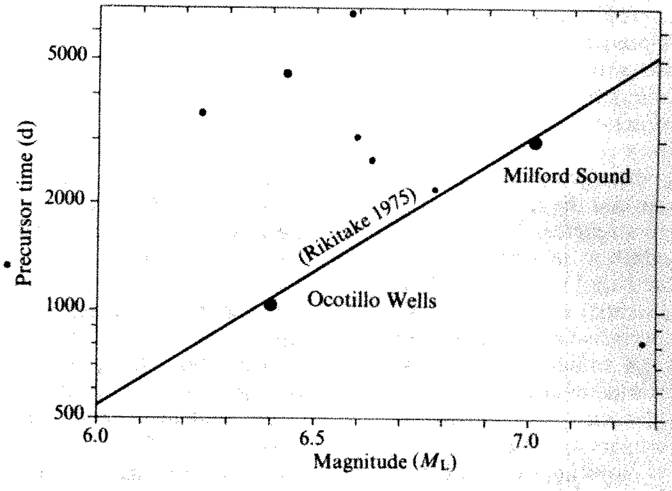

Fig. 5 Time interval between precursory swarm and major event, plotted against main-shock magnitude. Rikitake's curve is obtained from a plot of widely scattered data for eleven different types of precursory phenomena: land deformation, *b*-value, micro-earthquakes, source mechanism, fault creep, velocity ratio, velocity values, geomagnetic effects, resistivity, radon emission and oil flow.

The precursory swarm could be described as a rehearsal of the major event, but the gap is also an important feature of the precursor.

The premonitory value of the fluctuations of seismicity depends in the first instance on the successful recognition of a swarm as such. Magnitude level is no criterion as major events in the present sense of the term also occur at low magnitudes. The required criterion is provided by the distribution of magnitudes and, in particular, as mentioned above, by the absence of a main shock. This is illustrated in Fig. 4, which contrasts the two precursory swarms with the respective major events.

Taking the precursor time as the interval between swarm and major event (onset-to-onset) one obtains 2,994 d for the Milford Sound earthquake and 1,029 d for the Ocotillo Wells earthquake. These values are plotted against the magnitudes of the respective main shocks in Fig. 5. Also shown is the relationship obtained by Rikitake[1] based on other types of precursor.

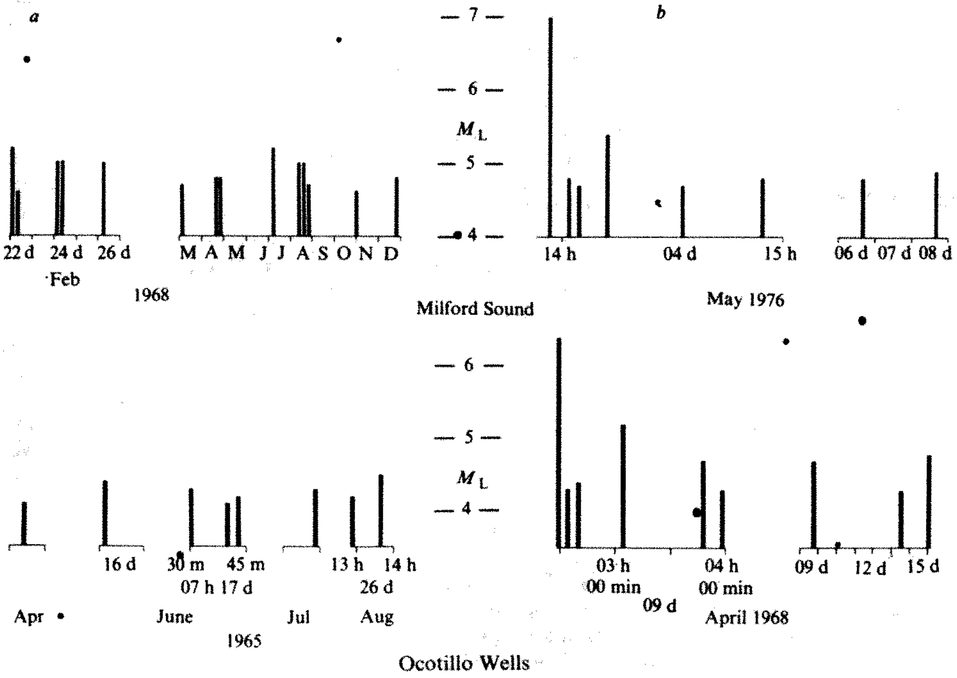

Fig. 4 Magnitudes of precursory swarm (*a*) and major event earthquakes (*b*). The time scales are not uniform.

The fluctuations of seismicity seem to have a physical origin closely related to that of the phenomena analysed by Rikitake. As with many of those phenomena the dilatancy hypothesis offers an interpretation of the precursory swarm. For at the onset of dilatancy the rock undergoes pervasive cracking which in an inhomogeneous medium can be expected to involve a redistribution of stress, leading in some localities to an increase beyond the strength. But as the general effect of the cracking is to strengthen the rock, only comparatively minor earthquakes result at this stage. The mechanism of the well-known swarm activity in regions of Quaternary volcanism may be similar in essential respects, as this activity may also be associated with pervasive cracking as the rock cools and shrinks[6].

A strategy of earthquake prediction has been suggested by Rikitake[1] in which an extremely long-range precursor would be identified by repeated geodetic surveys, and long-range precursors would then be sought by intensive geophysical methods. It now appears that fluctuations of seismicity may provide long-range precursory information from the normal output of a permanent seismograph network, without the use of intensive methods. Such methods could then be devoted to the search for short-term precursors.

Seismicity fluctuations have been identified in association with main shocks at magnitudes from 5.0 to 7.1. The phenomenon provides the following precursory information: the approximate location of the future major event is indicated at a prior time which is related to the magnitude of the main shock, and the area affected, although not always well defined, is also related to the magnitude. In addition, however, it seems that with the seismicity fluctuations the magnitude of the main shock increases with that of the swarm earthquakes; this relationship is potentially of great premonitory value and is now being investigated. Present studies are also leading to a detailed formulation of the characteristics of precursory swarms and to an assessment of the seismographic coverage required by the method at given levels of main-shock magnitude. On the basis of these studies the reliability of the method is being investigated preparatory to attempting actual predictions.

I thank Dr R. D. Adams for reading the manuscript.

Muon production of ^{92,94}Nb in the Earth's crust

ACTIVITIES due to long-lived ^{92}Nb ($t_{1/2} \simeq 1.7 \times 10^8$ yr) and to ^{94}Nb ($t_{1/2} = 2.03 \times 10^4$ yr) in a refined bar of terrestrial niobium were discovered by Apt *et al.*[1]. They speculated that the ^{92}Nb activity could have applications to chronologies of nucleosynthesis and to cosmogony. As an example, they calculated that their observed activity level would result if the isotopic ratio 4.7×10^9 yr ago were $^{92}\mathrm{Nb}/^{93}\mathrm{Nb} = 10^{-3}$ and if the halflife were 1.58×10^8 yr. More definite conclusions were difficult because the concentration expected today depends so strongly on the poorly known halflife, which they estimated to be 1.7×10^8 yr from a reactor irradiation. This sensitivity can be illustrated by noting that a 5% error in halflife corresponds after 4.7×10^9 yr to an error of a factor 2.74 in the anticipated activity. Quantitative calculations from galactic nucleosynthesis must therefore await a more precise measurement of the halflife. Implications of primordial ^{92}Nb have recently been enlarged with the proposal[2] to use enrichments $\delta(^{92}\mathrm{Zr})$ in the isotopic composition of Zr due to extinct ^{92}Nb to measure absolute time differences in the formation of meteorites and planets. If an initial $^{92}\mathrm{Zr}/^{94}\mathrm{Zr}$ ratio for each body can be obtained, differences between those initial values could be translated into time differences in the formation of the respective objects. We argue here that both projects are probably doomed to disappointment. It seems to us unlikely that the near equality in the two measured activities is a coincidence. They are respectively 0.058 ± 0.035 d.p.m. per kg (Nb) for ^{92}Nb and 0.32 ± 0.03 d.p.m. per kg (Nb) for ^{94}Nb. Such a result would be expected, for example, if both nuclei were created terrestrially over geologic time in the ratio of their activities, in this case in a production ratio $p(^{92}\mathrm{Nb})/p(^{94}\mathrm{Nb}) = 0.18 \pm 0.11$. We suggest that nuclear reactions following the capture of stopped cosmic-ray muons is the likely source, and we will show that both the magnitude of the activities and their relative strengths are consistent with this idea. Similar ideas have been developed by others, most notably to explain Xe anomalies in Te ores[3].

Examination of a chart of stable nuclides shows that ^{94}Nb in this model arises from the reactions ^{94}Mo (μ^-,γ) ^{94}Nb, ^{95}Mo (μ^-,n) ^{94}Nb, ^{96}Mo $(\mu^-,2n)$ ^{94}Nb, ^{97}Mo $(\mu^-,3n)$ ^{94}Nb, ^{98}Mo $(\mu^-,4n)$ ^{94}Nb, and by ^{93}Nb (n,γ) ^{94}Nb, where the neutrons are regarded as arising from muon capture on all species in the Earth's crust. On the other hand, ^{92}Nb would arise from ^{92}Mo (μ^-,γ) ^{92}Nb, ^{94}Mo $(\mu^-,2n)$ ^{92}Nb, and so on. We use a theory of muon capture as developed by Singer[4] in order to evaluate the various branchings following the muon capture. Molybdenum is the major target for direct production of Nb because charged-particle emission is much less probable than neutron emission. The major uncertainty in our results lies not in the theory, but in the unknown ancient history of the crustal rocks from which the Nb bar was purified. A time average of the Nb/Mo abundance ratio in these rocks enters, because only ^{94}Nb activity can be made by neutron capture on Nb whereas both Nb isotopes result from muon capture by Mo. A pure ancient Nb deposit, for example, would therefore contain only ^{94}Nb activity. Furthermore, the number of neutron captures by Nb per stopped muon depends on the chemical composition of the host mineral through its competition for the neutrons it produces. Apt *et al.* could not discover the history of the ores from which the Nb bar was refined, so we have calculated this competition for two idealised samples: (1) chondrite material, which presumably well represents the average heavy element abundances in the earth, and (2) typical terrestrial granites. Following Singer's description, we constructed a computer programme for calculating the distribution of neutron-emission multiplicities following muon capture on each relevant species, taking the surface-emission term to be 16%. Details of this calculation are given in ref. 5. For evaluating the absolute production, we took the muon stopping rate to be 100–150 muons g^{-1} yr^{-1} down to depths of about 10 m water equivalent[6]. If the ores were considerably deeper than this over the time-integrated production of the anomalous activities ($\sim 10^8$ yr for ^{92}Nb and $\sim$ 10^4 yr for ^{94}Nb), the absolute activities would be considerably reduced.

Table 1 shows major features of our calculation. We assumed the so-called Z-law[7]—that the atomic capture of muons in a mixture is proportional to the nuclear charge Z of the competing atoms—enabling us to calculate in a given composition the fraction of stopping muons captured by each element. In Table 1, $\langle Z \rangle$ is the average charge for each of the two background compositions. The average number $\langle \nu \rangle$ of neutrons emitted per muon stopped is also calculated, as is the average neutron-capture cross section $\langle \sigma \rangle$ of the nuclei of each composition. These allow us to calculate the fraction of the neutrons captured by ^{93}Nb, taking its thermal cross section[8] to be $\sigma = 1.15$ b. The compositional differences are dominated by the chondritic iron being much greater than granitic. The remaining entries in Table 1 show our calculated results for the numbers of each reacrtion occuring per muon stopped in that sample. For the chondritic composition this process is well defined, but for the granitic case we have to assume values for the Mo/Si and Mo/Nb abundance ratios in the rock. We take the latter ratio to be the chondritic value Mo/Nb = 2.2, an assumption that affects the calculated ^{92}Nb/^{94}Nb production ratio. The very small ratio, Mo/Si, does not affect the ^{92}Nb/^{94}Nb production ratio as long as Mo/Nb is held at 2.2; therefore we take it also to be chondritic Mo/Si = 2.5×10^{-6}. Within these assumptions, which are easily scaled to other choices, Table 1 lists the production resulting from each stopped muon in the sample. If the granitic Mo/Si differs from 2.5×10^{-6}, the calculated entry for μ^-–capture reactions scales proportionately, and if Nb/Si differs from 1.15×10^{-6}, the calculated entry for ^{93}Nb (n, γ) scales proportionately. Therefore, the granitic entries can be used more generally than for only the specific trace-element concentrations used in their calculation.

Table 1 ^{92,94}Nb production per stopped muon

	Granitic	Chondritic
$\langle Z \rangle$ matrix	10.4	11.9
$\langle \nu \rangle$, neutrons per muon	0.43	0.54
$\langle \sigma (n, \gamma) \rangle$ matrix(b)	0.16	0.39
^{97}Mo (μ^-, 5n) ^{92}Nb	2.3×10^{-9}	1.4×10^{-9}
^{96}Mo (μ^-, 4n) ^{92}Nb	1.7×10^{-8}	9.9×10^{-9}
^{95}Mo (μ^-, 3n) ^{92}Nb	3.3×10^{-8}	1.9×10^{-8}
^{94}Mo (μ^-, 2n) ^{92}Nb	5.8×10^{-8}	3.3×10^{-8}
^{92}Mo (μ^-, γ) ^{92}Nb	4.7×10^{-8}	2.7×10^{-8}
Total ^{92}Nb per μ^-	1.6×10^{-7}	9.0×10^{-8}
^{98}Mo (μ^-, 4n) ^{94}Nb	2.8×10^{-8}	1.6×10^{-8}
^{97}Mo (μ^-, 3n) ^{94}Nb	1.9×10^{-8}	1.1×10^{-8}
^{96}Mo (μ^-, 2n) ^{94}Nb	1.0×10^{-7}	6.0×10^{-8}
^{95}Mo (μ^-, n) ^{94}Nb	1.3×10^{-7}	7.6×10^{-8}
^{94}Mo (μ^-, γ) ^{94}Nb	2.4×10^{-8}	1.4×10^{-8}
^{93}Nb (n, γ) ^{94}Nb	7.8×10^{-7}	2.7×10^{-7}
Total ^{94}Nb per μ^-	1.1×10^{-6}	4.5×10^{-7}
^{92}Nb/^{94}Nb per μ^-	0.14	0.20

The calculated production ratios per captured muon, $p(^{92}\text{Nb})/p(^{94}\text{Nb}) = 0.14$ for granite and 0.20 for chondritic matter, bracket the steady-state production ratio 0.18 ± 0.11 needed to match the ratio of observed activities. Furthermore, the absolute concentrations are also about right. The observation[1] ^{92}Nb/^{93}Nb = 1.2×10^{-12} translates in our model granite to 8.7×10^3 atoms ^{92}Nb (g granite)$^{-1}$. If interpreted as a steady-state concentration, this number must equal the product 1.6×10^{-7} τ (^{92}Nb) λ_μ, where the coefficient comes from Table 1 and λ_μ is the muon stopping rate per gram of granite per year. The required stopping rate, $\lambda_\mu = 222$ g^{-1} yr^{-1}, is about 50% greater than the value[6] at a depth several metres water equivalent under the earth. Virtually the same stopping rate would be needed in chondritic material. The rough agreement in production ratio and in absolute yield attests strongly to the probable correctness of this explanation. Neutrons from other sources near the Earth's surface or from (α,n) reactions within the crust[1] may synthesise ^{94}Nb from ^{93}Nb, but the associated ^{92}Nb activity suggests that muons are a major source.

Major uncertainties exist in the history of the ore, of course, and these cloud firm conclusions. If deep material has risen to within 10 m from the surface, each activity within will have increased in time as muon reactions built the activity to saturation; however, since saturation requires roughly 10^8 yr for ^{92}Nb and only 10^4 yr for ^{94}Nb, time dependent effects can alter the activity ratio. There is also a major question of fractionation of Mo from Nb during the growth of these activities and the geologic processes leading to the mining sites. In pure Nb the ^{92}Nb/^{94}Nb activity ratio should be very small, whereas Table 1 shows in pure Mo it should be about 0.5. In principle, such variations could yield interesting evidence of geologic history, because the activities of these two isotopes should differ in Nb samples purified from ores having different geologic histories. Searches for these activities in old molybdenum ores should prove interesting. It would also prove helpful if a Mo bar could be exposed to a sufficient flux of stopping muons to experimentally determine the ^{92}Nb and ^{94}Nb activities, for then our calculated sums of branching ratios could be replaced by experimental numbers, greatly improving the accuracy.

The idea that the ^{92}Nb could be a remnant of galactic p-process nucleosynthesis is of course an attractive hope. But, we find little grounds for optimism from p-process systematics. Most p-process nuclei seem to be produced as proton-rich progenitors, in which case ^{92}Nb is shielded by ^{92}Mo. The ^{92}Nb is similar to other heavy odd–odd nuclei ^{138}La and ^{180}Ta, both of which are very rare and may be taken as empirical guides to p-process nucleosynthesis in such cases. Their abundances are 10^{-1} to 10^{-2} of characteristic p-abundances in their neighbourhood. Taking the same estimate for ^{92}Nb leads to a total ever produced $^{92}\text{Nb}_{\text{total}} \sim 0.02$ to 0.002 per 10^6 Si, where we have estimated the average $N_p = 0.2$ by averaging ^{84}Sr, ^{94}Mo and ^{96}Ru, excluding ^{92}Mo which is known to be anomalously large. A photodisintegration-flow p-process calculation[9] has recently yielded $^{92}\text{Nb}_{\text{total}} = 0.001$, an even lower estimate of total production. Our models of continuous nucleosynthesis suggest that about 2% of the total ^{92}Nb would have survived to the early Solar System; therefore $^{92}\text{Nb}_0 = 4 \times 10^{-4}$ to 4×10^{-5} per 10^6 Si, or $(^{92}\text{Nb}/^{93}\text{Nb})_0 = 3 \times 10^{-4}$ to 3×10^{-5}. This ratio could be enough to account for today's activity if $t_{1/2} \geqslant 1.7 \times 10^8$ yr, so again, one awaits a better halflife measurement. Even then, the expected amount is perhaps too small to expect to find δ (^{92}Zr) anomalies due to extinct ^{92}Nb[2].

Particulate organic carbon in Atlantic surface waters

PARTICULATE organic matter (POM) in the oceans has a vital role in marine ecology as it is the major food source for living organisms in surface and deep waters. Nearly all of the suspended organic matter in the oceans originates from phytoplankton productivity in the euphotic layers and is comprised of living plankton and dead organisms (detritus). Because of the importance in the marine food web of suspended organic phases in seawater several investigations on their distribution and composition have been carried out[1–3].

Most of the available data, however, are based on sampling at a single location and hence the magnitude of latitudinal variation in the POM concentrations are not well established. Chester and Stoner[4] have reported extensive measurements on the concentration of particulate organic carbon (POC) and particulate nitrogen (PN) in surface waters of the eastern Atlantic and Indian oceans. We present here results on the distribution of POC in the open ocean surface waters of the

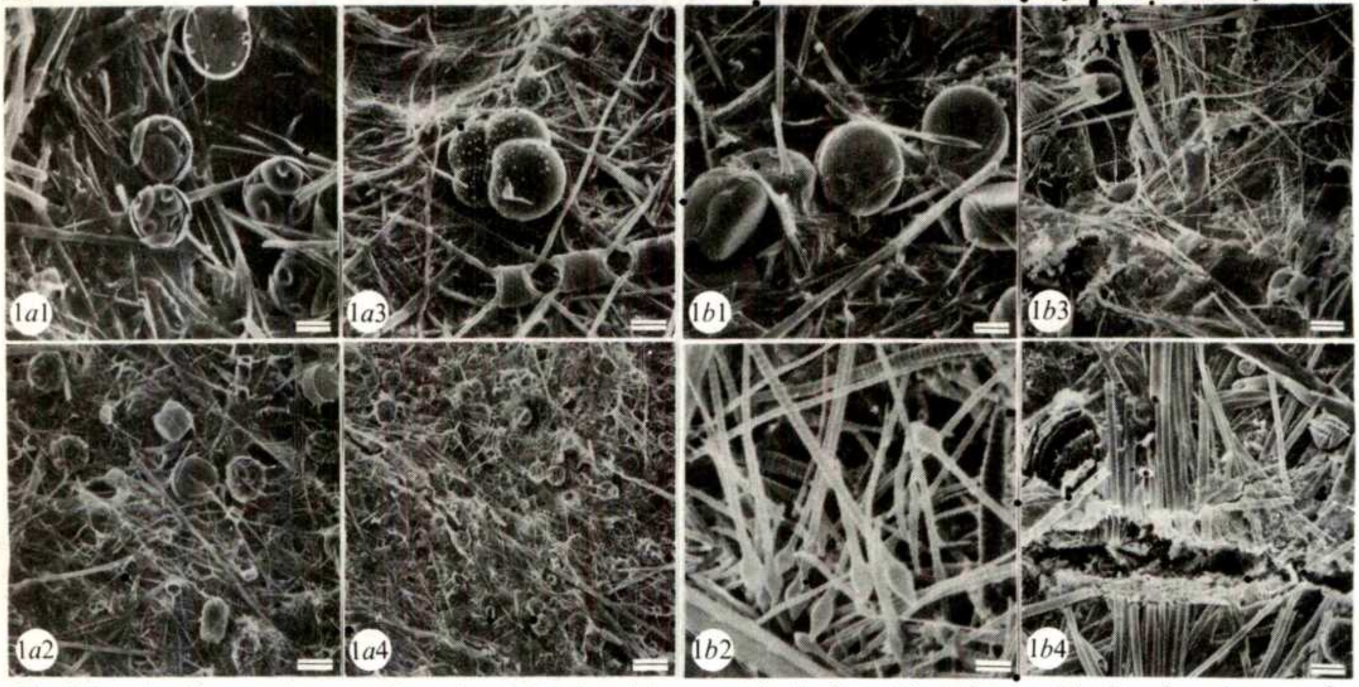

Fig. 1 Scanning electron microscope photomicrographs of particles trapped in the filters. Most of the particles in *a*, from the coast of Iceland and the Norwegian Sea, are calcareous (coccolithophoridas and forams); the large circular particle on the top and the rod-like particles are siliceous. In *b*, from the Antarctic and the equatorial waters, the particles are mostly siliceous. Scale bars: *a*1, 5 µm; *a*2, 10 µm; *a*3, 10 µm; *a*4, 20 µm; *b*1, 5 µm; *b*2, 5 µm; *b*3, 20 µm; *b*4, 20 µm.

Atlantic, between 72°N and 61°S; 60°W and 20°E, and its interrelation with primary productivity.

The samples were collected during the GEOSECS Atlantic expedition (July 1972–April 1973) by filtering large volumes (2,000–40,000 l.) of surface seawater while cruising between stations, usually 3° apart. Thus, the particles were trapped from representative samples of surface waters over hundreds of km. We used a cotton fibre filter with almost quantitative retention efficiency for particles > 5 µm and 60% for particles in the 0.5–1.2-µm range. The filter characteristics and filtration techniques are discussed in detail elsewhere[5]. The filters were rinsed with sufficient quantities of distilled water to remove sea salts, dried on board the ships at 90–100 °C, packed carefully and sent in poly-bags to shore-based laboratory for analysis. Figure 1 shows some of the trapped biogenic particles on the filter. The weight of total particulate matter (TPM) (the weight difference in the filter before and after the experiment) trapped per filter was 0.1–3.0 g. The samples were ashed at 400–425 °C, and the weight loss on ashing was attributed to POM. Particulate organic carbon content of the samples was calculated by assuming that it constitutes 50% of POM (ref. 7). The calculated particulate organic carbon is designated as CPOC henceforth.

The TPM and CPOC concentrations in surface waters ranged between about 10–600 and 2–170 µg kg^{-1}, respectively, and are strongly interrelated (Fig. 2). The latitudinal distributions of TPM and CPOC concentrations (Fig. 3) are similar, with pronounced maxima near subpolar regions (~60°N and 60°S) and low concentrations in the tropics and mid-latitudes (30°N–40°S).

The relation between TPM and CPOC for the surface Atlantic suspended phases in different latitudinal belts are given in Table 1. The mean TPM/CPOC for the Atlantic (72°N–61°S; 60°W–20°E) is 3.94, corresponding to a mean CPOC content of ~25%, that is, ~50% POM. The remaining ~50% of TPM is composed of biogenic skeletal remains, ($CaCO_3$ and opal) and terrestrial materials (aluminosilicates, quartz). The TPM/CPOC ratios exhibit geographical variations (Table 1, Fig. 2). For samples from northern subpolar regions (45–72°N) the mean ratio is (3.57±0.38) compared to a value of (4.8±0.7) for samples from 45–61°S. The samples from the 45°N–45°S region have the lowest TPM/CPOC ratio, 3.15±0.18. The observed TPM/CPOC ratios are in good agreement with results of Chester and Stoner[4]. The differences in the TPM/CPOC ratios in various regions seem to be due to variations in the elemental composition of biogenic populations

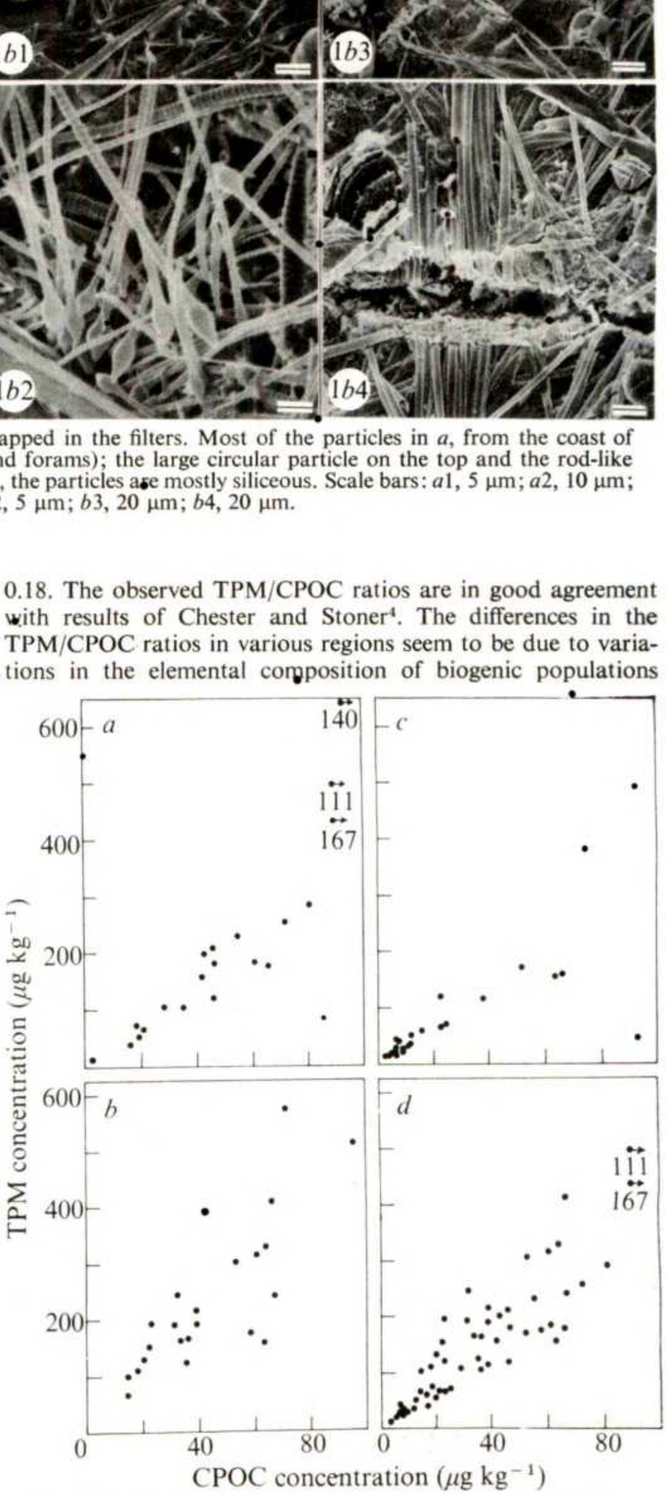

Fig. 2 Correlation diagram for the TPM–CPOC concentrations for various regions of the Atlantic surface waters. The linear correlation between TPM and CPOC is evident. Note that CPOC constitutes about 20% of TPM in samples from Antarctic circumpolar region compared to ~30% for rest of the Atlantic. Only samples having ⩾ 200 mg weight loss during ashing were taken to avoid possible uncertainties due to weightloss of filter during filtration. *a*, 72°–45°N; *b*, 45°–61°S; *c*, 45°N–44°S; *d*, 72°N–61°S.

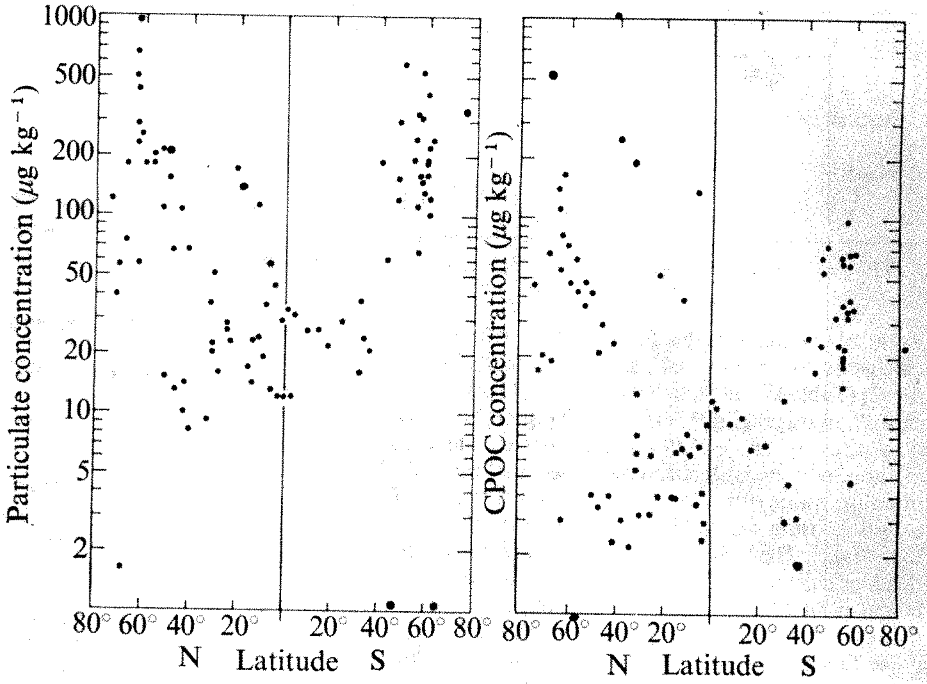

Fig. 3 Latitudinal distribution (72°N–61°S) of TPM and CPOC in Atlantic surface waters. The distribution patterns for both TPM and CPOC are almost identical, with pronounced maxima in the subpolar regions due to high organic productivity. Low concentrations have been observed for waters between 30°N and 30°S.

occurring in these bands. Our detailed analyses[8] indicate that siliceous tests dominate in the Antarctic circumpolar waters (40°–60°S) whereas calcareous tests are relatively more abundant in the North Atlantic (Fig. 4).

The regional differences in the CPOC concentrations of surface waters can be roughly correlated with nutrient supply due to upwelling and phytoplankton activity. In the North Atlantic, high CPOC concentrations were observed in the Denmark Straits and off the coast of Iceland, where upwelling of nutrient-rich waters caused by passage of strong currents over the Iceland–Faroes Ridge occurs, and in the Canary Islands, where cool nutrient-rich water ascends to the surface due to off-shore wind action[9]. Similarly, CPOC concentrations are high south of the Antartic Convergence zone, where very high primary productivity has been observed due to upwelling of circumpolar waters. Lowest CPOC concentrations are in the western Atlantic, between 30°N and 30°S. Our results have the following implications: (1) Organic biological matter constitutes ~50% by weight of the total suspended matter in the Atlantic Ocean. (2) Organic carbon in sediments constitutes only ~0.3% compared to a value of ~25% in surface particulates. This suggests that most of the organic carbon produced in surface waters dissolves within ocean water. (3) The mean residence time of particulate organic carbon within the top (100–200-m) layer against consumption by dissolution and grazing is deduced to be about 5–10 d. This is based on the ratio of the standing crop of particulate carbon (from our measurements in surface waters) and its primary production rate[12]. The standing crop of particulate organic carbon, $\Sigma\mathrm{POC} = C_s L$, where C_s is the surface concentration and L is the mean concentration depth, the depth over which the concentration decreases by a factor of e. The

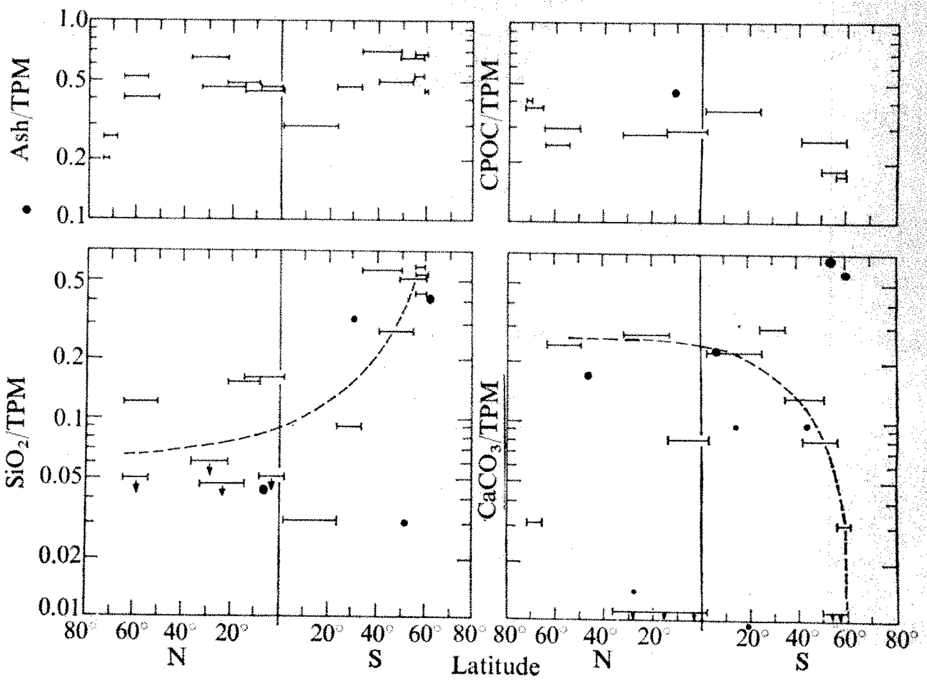

Fig. 4 Latitudinal variation of the ash, CPOC, CaCO$_3$ and SiO$_2$ contents of TPM from surface Atlantic waters. The CaCO$_3$ is relatively more abundant in the northern latitudes, whereas samples from ~60°S contain mainly siliceous organisms.

Table 1 TPM, CPOC interrelation for surface Atlantic waters in various latitudinal belts

Latitudinal belt	No. of samples	CPOC concentration ($\mu g\ kg^{-1}$) Range	Mean	TPM–CPOC relation* ($m \pm \Delta m$)	C	Correlation coefficient for TPM–CPOC relation
72°N–45°N	19	17–167	59	(3.57 ± 0.38)	0.9	0.92
45°N–45°S	28	3–52.5	12	(3.15 ± 0.18)	3.8	0.96
45°S–61°S	22	14.5–96	44	(4.8 ± 0.7)	20.3	0.81
72°N–61°S	69	3–167	35	(3.94 ± 0.25)	10.2	0.89

*TPM = $(m \pm \Delta m) \cdot$ CPOC+C, where TPM and CPOC are their concentrations in $\mu g\ kg^{-1}$ and C is a constant.

value of ΣPOC for the (45°N–45°S) belt in the Atlantic is calculated to be about 60 $\mu g\ cm^{-2}$ using a value of 12 $\mu g\ kg^{-1}$ for C_s (Table 1) and 50 m for L (refs 12, 13). Primary production rate, P, in this region[14] is about 100 $mg\ m^{-2}\ d^{-1}$. The consumption time, τ_c ($\tau_c = \Sigma POC/P$) of particulate organic carbon in these regions is thus estimated to be about 6 d. The corresponding value for the Atlantic surface waters (72°N–61°S) is ~9 d, using $C_s = 35\ \mu g\ kg^{-1}$, $L = 50$ m and $P = 190$ mg C $m^{-2}\ d^{-1}$. The estimated value for τ_c refers to both living and dead organisms. The mean survival time for living organisms is much smaller, about 1–2 d, as the ratio[1] of living phytoplankton to detritus is approximately 1:6.

(4) The average SiO_2/CPOC molar ratio in particles from the circumpolar waters (~60°S) is about 0.4. Thus in the Antarctic polar front, biological productivity (primarily siliceous organisms) converts 0.4 mol of soluble silica into suspended phases per mol of carbon. Biogenic silica constitutes more than 90% of the total particulate silica at 50–60°S.

(5) The non-uniform distribution of the TPM and CPOC concentrations suggests that horizontal mixing due to surface currents is not effective in homogenising the particle concentrations; the sinking rates of these suspended phases, therefore, must be faster than the surface current velocities. As most of the CPOC (~95%) dissolves in the water column before being deposited as sediment, the trace elements associated with particulate organic carbon phases are also expected to be injected in seawater in dissolved form. If so, the dissolution flux of elements could also have geographical dependence governed by primary productivity in various latitudinal bands. The dissolution flux of elements associated with the hard skeletal part of the organisms (for example, $CaCO_3$ and opal) will similarly show geographical variation, as the $CaCO_3$/TPM and SiO_2/TPM ratios vary considerably in surface waters.

Nickel in komatiites

THE principle of partitioning of trace elements between magma and crystalline phases is an extremely useful tool in deciphering the origin and evolution of magmas. With our present knowledge of partition coefficients calculations usually assume them to be constant. The nickel contents of suites of komatiitic lavas from South Africa, the evolution of which is controlled by olivine fractionation, suggest that the partition coefficient for nickel between olivine and liquid is not constant, but increases from <3 for liquids with >20% MgO and >1,000 p.p.m. Ni to 11 for liquids with 10% MgO and 200 p.p.m. Ni. There are two fundamentally different views on the origin of basic magmas. O'Hara[1] proposed that the mantle melts to produce a picritic liquid which undergoes extensive olivine fractionation prior to eruption. The alternative model, summarised by Ringwood[2], assumes that basic magma is a direct product of melting and undergoes no fractionation. Ringwood's rejection of the fractionation hypothesis is based largely on calculations of the Ni content of magmas[2]. All his calculations assume a constant partition coefficient for Ni between olivine and liquid in the range 12–15. Several recent investigations concluded that K_D is not constant but that it decreases (1) with increasing temperature[3,4]; (2) with increasing MgO content in the liquid[5]; (3) with increasing Ni content in the liquid[6], and (4) as crystallising olivines become more forsteritic[7]. These effects have been reviewed in detail elsewhere[8] but the net effect is that for a liquid, rich in MgO and Ni, crystallising a forsteritic olivine at high temperature, K_D may be significantly lower than the figure currently accepted. Komatiitic lavas fall perfectly into this category of liquid as they have high MgO and Ni contents and it has been shown experimentally[9] that they crystallise very magnesian

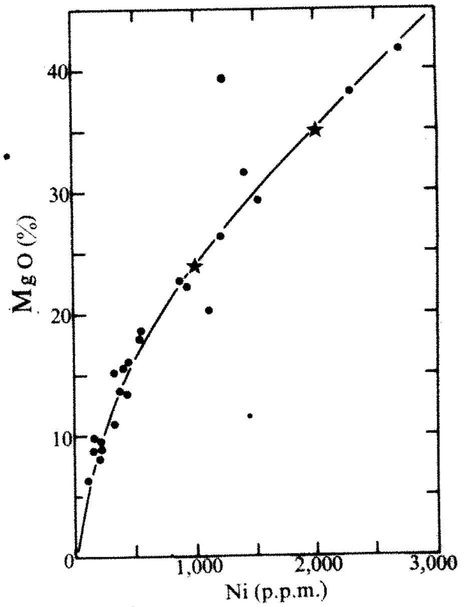

Fig. 1 Plot of Ni against MgO contents of komatiites analysed in Table 1. Stars denote proposed parental magma compositions.

olivines at temperatures well above the liquidus for normal basalts. Most of the studies which have indicated low K_D values have involved experimental work on synthetic samples[4–7], some of which[5–7] were iron-free and hence, although they represent an extremely important step towards understanding partition coefficients, quantitatively the K_D values may be suspect. We have analysed the Ni contents of komatiites with a wide range of compositions to determine the partition coefficient for these seldom-erupted lavas to test more rigorously the constraints imposed by Ni values on the fractionation model for basic magmas.

C indicates MgO content is higher than in the theoretical parental magma used in the calculations and hence is regarded as a cumulus-enriched rock. S3–S28 from Anhaeusser (unpublished), OV3–OV5 from ref. 11, SG3–LV7 from ref. 10.

*F, proportion of liquid remaining is (100—% olivine removed)/100.

The geological relations for most of the komatiites chosen for analysis (from the Barberton Mountainland in South Africa) have been described elsewhere[10]. All the samples are demonstrably lavas; as indicated by pillow structures, vesiculation or spinifex textures; except sample 53J which is the chilled margin of a dyke. Their MgO and Ni contents are given in Table 1 (complete major element analyses have been published for most samples (refs 10, 11 and C. R. Anhaeusser, unpublished)). The values are calculated on an H_2O^+-free basis (Fig. 1), and a very close correlation between Ni and MgO is apparent. It has been suggested[10,12] that these samples are related by olivine fractionation, and hence for these suites of lavas we have an opportunity to study the variation in Ni content produced by the removal of olivine.

Green *et al.*[9] have suggested that komatiitic samples containing 35% MgO represent liquids while McIver[12] and Cawthorn and McIver[13] believe such compositions to be cumulus-enriched in olivine and that the true liquids contain significantly less than this. Here we interpret the data using two hypothetical parental magmas, one with 35% and the other with 24% MgO. Figure 1 suggests that such liquids contain 2,000 p.p.m. and 1,000 p.p.m. Ni respectively. The olivine composition which crystallises from these magmas is approximately Fo_{93} which contains 51% MgO (ref. 9). Starting with parental magmas containing 35% and 24% MgO it is possible to calculate the degree of olivine fractionation required to produce the MgO contents of residual liquids with the MgO values given in Table 1. These calculated degrees of fractionation are also listed in Table 1: models 1 and 2 referring to parental magmas with 35% and 24% MgO respectively.

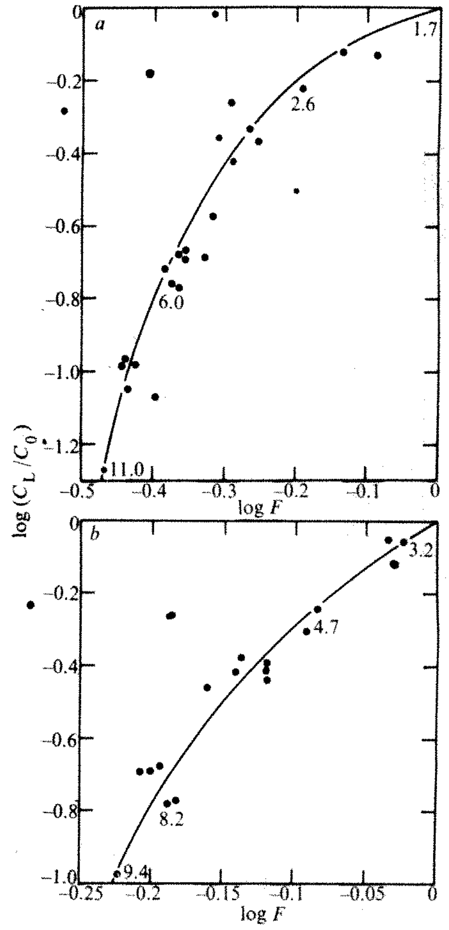

Fig. 2 Plot of log (C_L/C_0) against log F. Slope of graph is $K_D - 1$ (as shown in text) and values for K_D are given at various points. *a*, Data for model 1 which assumes the parental magma contains 35% MgO and 2000 p.p.m. Ni. *b*, Model 2 for a parental magma with 24% MgO and 1,000 p.p.m. Ni.

The Rayleigh fractionation law states $C_L/C_0 = F^{K_D - 1}$ where C_0 is the trace element content of the parental magma, C_L that of the differentiated magma; F the proportion of differentiated magma produced, and K_D the partition coefficient. This may be rewritten as $\log(C_L/C_0) = (K_D - 1)\log F$.

Assuming 2000 p.p.m. (model 1) and 1000 p.p.m. Ni (model 2) for C_0 and having calculated the value for F from Table 1 we can plot a graph of log (C_L/C_0) against log F (see Fig. 2) and this will give a slope of $K_D - 1$. It is readily apparent from Fig. 2 that the graphs are not linear and hence the partition coefficient cannot be constant. The slope of the curves has been calculated at various points and the value for K_D, derived from the slopes, included in Fig. 2. Considering the model proposed by Green *et al.*[9], the initial slope of the curve is 0.7 and hence K_D is 1.7. (It is interesting to note that the experimentally determined K_D of Green *et al.*[9] is only 2.1 and hence agreement between experiment and these calculations on natural samples is extremely good.) At the extreme end of differentiation considered here, for liquids containing 6.37% MgO, the K_D as calculated from the slope of the graph is 11. Alternatively, if we consider model 2 the initial partition coefficient for liquids containing 24% MgO is 3.2 and has a maximum value of 9.4. Pyroxenes may begin to crystallise from magmas with low MgO contents. Hence, it may be that some of the most differentiated liquids of this study are not the product of fractionation of olivine alone. The K_D values determined for these low MgO liquids may not therefore apply to olivine : liquid partitioning, but this will not qualitatively alter the arguments presented here.

The values for the partition coefficient for low MgO-liquids (<8% MgO) are fairly close to those predicted for basic magma[14]. Hence, for such compositions the partition coefficients determined for these komatiites and other magmas appear compatible. For the MgO-rich compositions, however, the values are very much lower.

With reference to the debate between Ringwood and O'Hara mentioned earlier we conclude for the partition coefficients calculated here that: (1) the primary picritic magma envisaged by O'Hara[1] may contain very much higher nickel contents than suggested by Ringwood[2] because the partition coefficient is much lower. And (2) the rate at which nickel will be extracted from this parental magma by olivine fractionation will be slower than anticipated by Ringwood[2]. Specifically, it is apparent from Table 1 that an initial magma containing 24% MgO and 1000 p.p.m. nickel may undergo 40% olivine fractionation to produce a residual liquid with 6% MgO and 100 p.p.m. nickel—values perfectly compatible with those of typical basic magmas. O'Hara[1] does not quantify his melting and crystallisation models, but these figures presented above suggest that the variation in partition coefficients makes his models qualitatively more tenable.

Rhythm perception in early infancy

THE chief characteristic of rhythm perception is the subjective grouping of objectively separate events. In a rhythmic sequence of identical tone-bursts, adults do not perceive the repetition of a single sound, but a recurring configuration which has temporal form. Such a sequence is organised according to the Gestalt law of proximity[1,2]. Organisation of temporal form has never been studied systematically in pre-verbal infants. We present here results suggesting a precocious achievement of this function and contrasting with previous research[3] which failed to demonstrate organisation of spatial form by babies in accordance with the proximity law.

We adopted an habituation paradigm in which infants received auditory reinforcement contingent upon their visual fixation on a simple patterned-figure: a black outline-square on a white background. The infants themselves initiated the presentation of sound by looking at the figure and terminated it by looking away. After several such fixations, the auditory reinforcement was changed from one sound sequence to another. Any resulting increase in time of fixation on the visual stimulus was an index of discrimination.

Sequences of tone-bursts were presented by a loudspeaker placed directly behind the stimulus figure at a distance of 40 cm from the infant. The tone-bursts, 40 ms in duration, were derived from a tape-recording of a consonant chord produced by an electronic organ, with 270 and 1,620 Hz as dominant frequencies; intensity was 63 dB, about 25 dB above the ambient noise level. The stimulus figure subtended a visual angle of 8° and was positioned 20° to the left of midline. Fixation, as assessed by the corneal reflection technique[4], was observed from directly in front of the infant, through a small hole in the screen containing the figure. The infant was judged to be fixating when, his eyes being turned to the left, the stimulus reflection was clearly observable over the right of the pupillary opening. Duration of fixation, to the nearest tenth of a second, was recorded manually by a switch which simultaneously operated sound-emission and an event-recorder. In previous research, a high inter-observer reliability has been obtained for this measure[5].

The first experiment was designed to demonstrate discrimination between the rapid, quite different sequences, S1 and S2, shown in Fig. 1. A regular pulse of tone-bursts, S1, was changed to an irregular sequence, S2. The two sequences had the same mean density of sound. We tested two samples, each of 10 infants, with mean ages of 71 d (s.d. 12) and 107 d (s.d. 6) respectively. Three fixations without sound reinforcement were followed by 12 fixations reinforced by S1 and then three fixations reinforced by S2. Median fixation times are shown in Fig. 2*a*. A significant increase in fixation time followed the change in reinforcement ($F = 10.37$, $P < 0.005$), indicating discrimination of the two sequences. No main or interaction effect was associated with age.

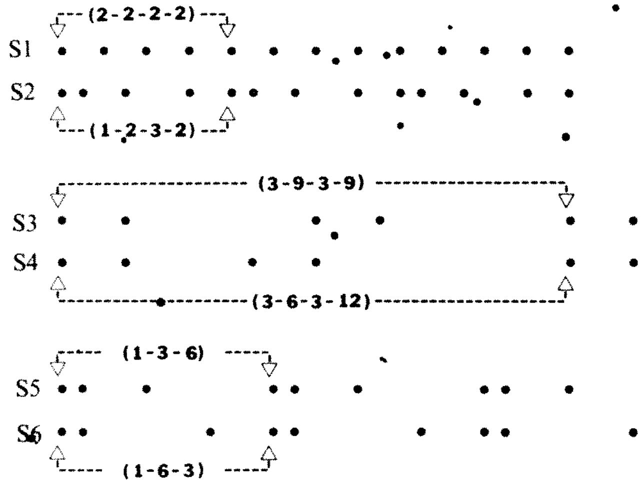

Fig. 1 Sound sequences. Each dot represents a 40-ms tone-burst. The shortest onset-to-onset interval was calibrated as 97 ms. All intervals were multiples of this unit. Their relative magnitudes in each sequence are given in brackets. Arrows delimit the period of each sequence. For example, the period of S2 is a succession of 1, 2, 3 and 2 time units (that is 97, 194, 291 and 194 ms). A sequence started always at the beginning of its period, and terminated when visual fixation ended (experiment 1) or after completion of the period in progress at that instant (experiments 2 and 3). Scale bar represents 1 s.

In a second experiment, we studied discrimination of slower rhythms, using the sequences S3 and S4 depicted in Fig. 1. The visual fixations of 10 infants (mean age 69 d; s.d. 18) were contingently reinforced nine times by S3 and then three times by S4. Fixation time increased ($t = 3.72$, $P < 0.005$) when S4 replaced S3 (Fig. 2*a*). Thus, the 6-unit intervals of S4 were discriminated from the 12-unit intervals of S4 or from the 9-unit intervals of S3; alternatively, a new ratio of intervals was detected in S4. In any case, we conclude that infants are able to perceive intervals of six units (582 ms) as subjective links between sounds.

The aim of the third experiment was to examine perception of temporal form in sequences differing only in the order of their intervals. In the preceding experiment, discrimination might be attributed solely to the detection of a new interval. In experiment 3, however, the same intervals were used in both sequences, and the minimum segment for distinguishing between them was composed of a pair of successive intervals. Thus, the grouping of three consecutive sounds into a perceptual configuration was mandatory if discrimination was to occur. The longest interval appearing in S5 and S6 (Fig. 1) had already been shown to be

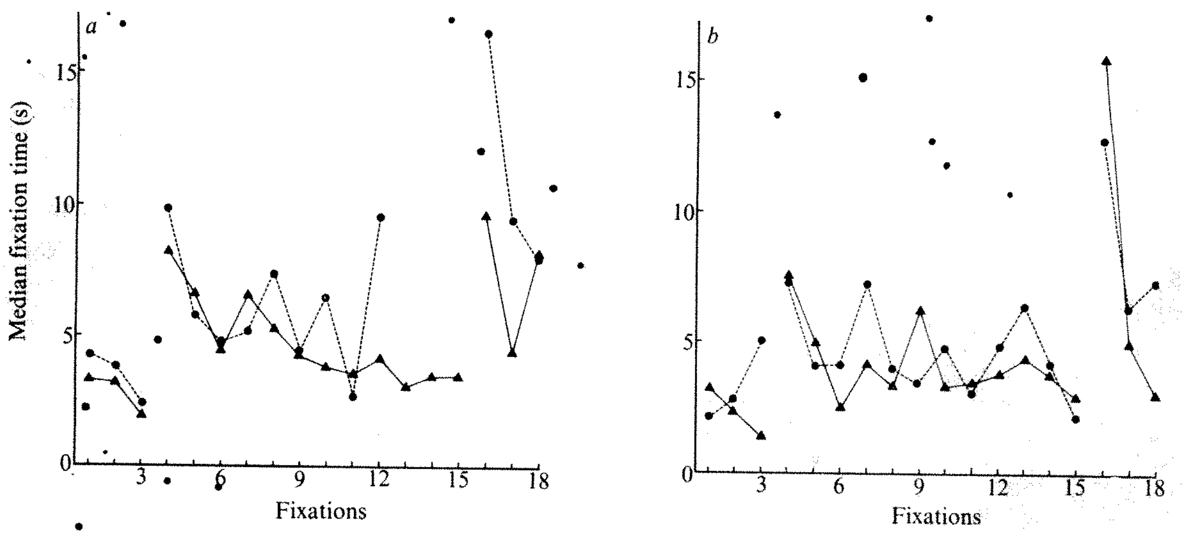

Fig. 2 *a*, Median time of fixation in experiments 1 and 2. In experiment 1 (▲), there was no sound reinforcement for fixations 1–3. S1 was presented contingently with fixations 4–15, and S2 with fixations 16–18. In experiment 2 (●), there was no sound reinforcement for fixations 1–3. S3 was presented contingently with fixations 4–12, and S4 with the final three fixations. The duration of the first fixation after change of reinforcement was compared with the mean duration for the preceding three fixations. *b*, Median time of fixation in experiment 3. No sound reinforcement was associated with fixations 1–3. For Group 1 (●), S5 was presented contingently with fixations 4–15 and S6 with fixations 16–18. For Group 2 (▲), the order of sequence presentation was reversed. The duration of fixation 16 was compared with the mean duration for fixations 13, 14 and 15.

perceptible in experiment 2. Therefore, within each reinforcement, all the sounds may have been linked in a temporal continuum. The first interval in each sequence was the same in order to ensure that discrimination was not based solely on a difference in this first interval, without further grouping. To adults, the sequences sound like recurring groups of three pips, the groups (. .   .) in S5 being perceived as the inverse of the groups (.   . .) in S6. In all emissions of S6, however, the first and final groups were incomplete (see Fig. 1). We tested two samples, each of 10 babies. Group 1 (mean age 69 d; s.d. 12) was tested in the order S5 followed by S6, and Group 2 (mean age 70 d; s.d. 18) was tested in the reverse order. Median fixation times are shown in Fig. 2*b*. An increase in fixation time followed the change in sequence ($F = 11.81$, $P < 0.005$); order of testing was associated with no reliable main effect or interaction. Since the differentiating of these sequences entails the grouping of three successive sounds, we infer that they were perceived as recurring 'rhythmic groups' organised in temporal form according to the Gestalt law of proximity. In addition, it may be noted that, following the first half-second, the rhythms can be distinguished only by the order of the within-group intervals. The magnitude of the novelty response suggests that, rather than perceiving only a single, very brief change, the infants have also noted the repetitive difference in within-group structure.

A succession of several sounds was apprehended by babies as a psychological unit. This phenomenon of temporal grouping is, of course, not peculiar to rhythm perception. Language comprehension, for example, requires a similar process, since a semantic unit must be grasped as a whole, despite its sequential character. In the results reported here, perceived structure rests on a purely temporal variable: the relative values of the intervals between sounds. These results indicate that skills of temporal analysis and synthesis, prerequisites for operating with the sequential dimension of language, are present well before the stage of speech, and suggest that the early experience of time is more complex than is generally assumed.

We thank the staff and mothers of the infant centres: 'Enfance et Famille', Paris, and 'P. M. I. Georges Braque', La Courneuve. D. Demany designed and constructed the electronic equipment.

The whalebill is a stork

THE avian order Ciconiiformes contains a heterogeneous assemblage of long legged, long necked birds which have traditionally been classified together because of superficial resemblance. The order usually contains the storks, ibises, herons and two rather aberrant birds, the whalebill (*Balaeniceps rex*) and the hammerkop (*Scopus umbretta*), which are placed in monotypic families, the Balaencipitidae and Scopidae, respectively. The evolutionary relationships among the members of the Ciconiiformes and between this order and other living birds are little understood. Using an analysis of the morphology of the stapes (the single avian ear ossicle)[1,2], I have obtained evidence for the evolutionary affinity of the whalebill with the storks, which now seem to form a monophyletic assemblage.

The whalebill, whalehead or shoebill (Aves: *Balaeniceps rex*) is a strange, storklike bird with an enormous swollen head and a hooked beak. It is restricted to marshes and riverine situations in eastern Africa from the southern Sudan to Zambia. It is largely nocturnal, and feeds on various vertebrates including frogs, snakes and even lungfishes, but also molluscs and carrion. It has many similarities with the true storks (including bill clattering behaviour), but its systematic position has always been uncertain. Recently it has been thought to have more similarities with the pelecaniform birds (order Pelecaniformes), while the resemblance to storks was thought to be superficial[3]. The characters used, however, were not analysed on the basis of primitive and derived states.

Study of the morphology of the stapes, or columella, makes possible a reassessment of the evolutionary affinities of the whalebill and the storks. The stapes is of great evolutionary significance as sequences of primitive to derived characters can be established beyond reasonable doubt. The typical avian stapes is reptilian, with a flat footplate and a straight bony shaft emanating from the centre of the footplate. Several avian groups, however, have unique, derived stapedial morphologies. I have assumed that: (1) the stapes found in most birds (most of the non-passerines and the suborder Passeres of the Passeriformes, which I now restrict to a separate order Passeriformes[1,2]) is homologous with the same element in reptiles, and represents a retained primitive condition, and (2) where pockets of derived stapedial morphologies occur, they indicate evolutionary relationships, unless there are compelling reasons to assume that convergent evolution has occurred.

I have examined the stapes of the whalebill (*Balaeniceps*), 23 species of herons (13 genera), 10 species of ibises (8 genera), and 11 species of storks (9 genera), including the small form, *Ciconia abdimii* (75 cm long), to avoid anatomical effects due to allometric growth; most storks are large birds. I have also studied the stapes of the monotypic family Scopidae, which contains the equally enigmatic hammerhead or hammerkop (*Scopus umbretta*), a species also confined to Africa south of the Sahara. All specimens were from the collections of the US National Museum and the University of Michigan.

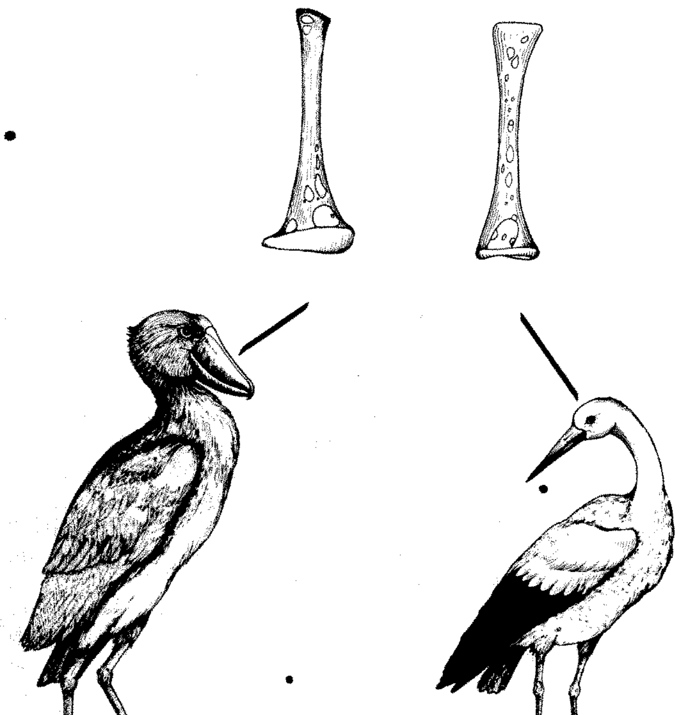

Fig. 1 Left, the whalebill (*Balaeniceps rex*), and right, the white stork (*Ciconia ciconia*), with lateral views of their stapes or columellae above; stapes drawn to the approximate same scale. The proximal ends are lower. Drawn by Ms Melissa Marshall.

I found that all the herons (Ardeidae, including the boat-bill, *Cochlearius cochlarius*), all the ibises (*Threskiornithidae*) and *Scopus* (Scopidae) have the primitive condition of the stapes, thus revealing nothing of their phylogenetic relationships, while all the storks and the whalebill have an identical, derived stapedial morphology. Pelecaniform birds have various stapedial morphologies that will be described in detail later together with those of the groups considered here, but they are quite different, elongate, somewhat curved structures. The stapes of the storks and whalebill (Fig. 1), here termed the stork stapes, is characterised as a broadly tubular structure that enlarges slightly at the footplate region, and exhibits numerous fenestrae along the entire surface, usually with one or several large openings at the base near the footplate. Such a derived stapedial morphology common to the storks and the whalebill is interpreted as compelling evidence that the storks as defined at present are monophyletic and that the whalebill (*Balyaeniceps*) is derived from them. Some authors[4] have made a case (primarily on osteological grounds) that the storks and New World vultures (Cathartidae) are closely allied; however, all of the cathartids possess the primitive stapedial morphology.

Early viral functions of *in* (ts)-1501 temperature-sensitive SV40 mutant

TEMPERATURE-SENSITIVE (ts) virus mutants have been useful in defining virus–host interactions in SV40 productive and transforming infections. We have isolated an SV40 ts mutant, *in*(ts)-1501, by extracellular mutagenesis, using ultraviolet radiation of wild type (WT) SV40[1]. The mutant, which has properties different from previously described SV40 ts mutants[2,3], is activated from its integrated state in nonpermissive transformed cells at temperatures above 39 °C and is capable of productive infection in permissive cells at elevated (conditional) temperatures[1]. Many properties of the *1501* mutant are analogous to the early ts cI mutants of bacteriophages in which a heat-inactivated protein cannot maintain the stable integration of the prophage in the bacterial chromosome at elevated temperatures[4-8]. This analogy suggested that maintenance of SV40 DNA integration in transformed cells requires an early viral function, that is, before the inception of viral DNA replication. Therefore we have investigated the effect of the *in* gene mutation on two other early virus functions—stimulation of host-cell DNA synthesis and tumour (T)-antigen synthesis.

Ts*A* mutants, the only previously identified mutants mapped in the early region of the SV40 genome[9], show normal induction of host-cell DNA synthesis at 40 °C, but some show a reduced induction at 42.5 °C (ref. 10). We studied stimulation of host-cell DNA synthesis in *1501* ts mutant-infected and WT SV40 strain 777-infected confluent TC7 cells. TC7 is a continuous line of African green monkey kidney cells that is permissive for SV40 productive infection[11]. The results (Table 1) indicate that the *1501* mutant can induce host-cell DNA synthesis at both conditional and nonconditional temperatures.

SV40 T-antigen, a nonstructural virus-coded protein, is expressed in the nuclei of productively and abortively infected and transformed cells. Approximately 30–40% of the SV40 genome is represented by this protein, the molecular weight of which has been estimated to be 70,000–100,000 (refs 12 and 13). The T-antigen is the SV40 *A* gene product, as defined by the ts*A* group of SV40 mutants[13-17]. Although Brugge and Butel[18] found that the synthesis of T-antigen was not temperature-sensitive in ts*A*-transformed or productively infected cells, Robb *et al.*[14] showed that cells productively and abortively infected by these mutants had decreased T-antigen expression at the conditional temperature, and Osborn and Weber[15] found that T-antigen decreased with time at the elevated temperature in ts*A*-transformed cells. Tegtmeyer *et al.*[13] found that, at the conditional temperature, the ts*A* mutants had an increased turnover of

* Cells, growing in 60-mm Petri dishes, were maintained in Eagle's minimal essential medium supplemented with 2 mM glutamine and 2% heat-inactivated (56 °C, 30 min) foetal bovine serum. Cell cultures were incubated in dark, water-saturated, 5% CO_2, temperature-regulated incubators. Virus was adsorbed for 1 h at 37 °C, followed by the addition of medium and then incubation at either 37° or 41 °C. The cells were labelled 20 h after infection with ^{3}H-dT (0.5 μCi ml^{-1} specific activity 6.7 Ci mmol^{-1}, New England Nuclear) for 90 min. DNA was selectively extracted by the method of Hirt[26]. The Hirt precipitate consisted of cellular DNA and the supernatant consisted of viral DNA. All determinations are average counts from triplicate Petri dishes.

T-antigen and an altered intracellular distribution in both productively infected and transformed cells at the elevated temperature. Tenen *et al.* [16] and Alwine *et al.*[17] found that T-antigen induced by ts*A* mutants is more thermolabile than that induced by WT virus.

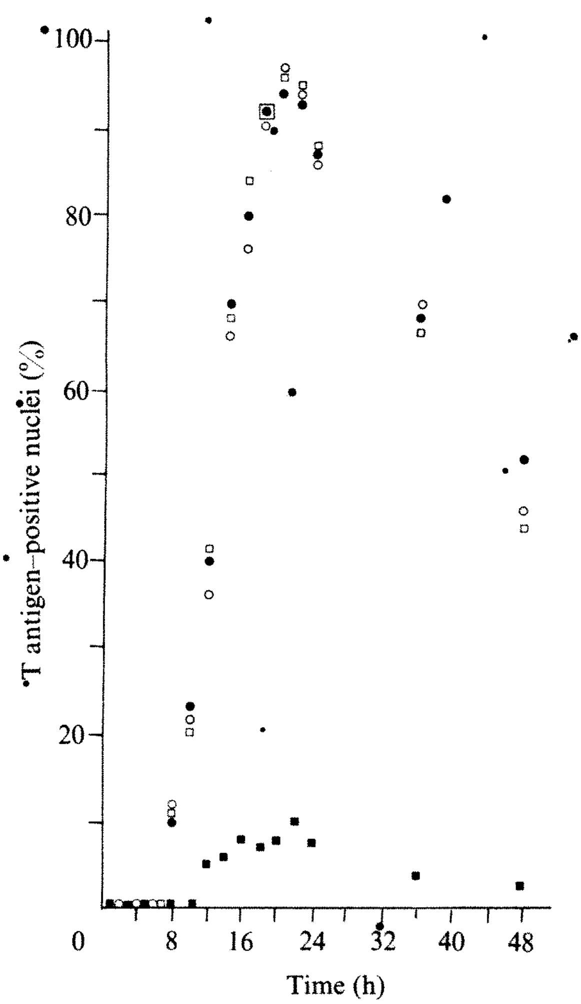

Fig. 1 Monolayers of African green monkey kidney cells (TC7) growing on coverslips in 60 × 15-mm plastic Petri dishes were infected with a multiplicity of infection of 10 by either wild type or *in*(ts)-1501 virus. After adsorption of the virus for 1 h, medium was added to the plates. Those cells infected with WT virus were incubated at 37 °C (○) or 41 °C (●). Plates with *1501*-infected cells were also incubated at 37 °C (□) or 41 °C (■). Each point represents the percentage of T-antigen-positive nuclei determined in 2,000 cells. Cells, fixed on coverslips, were stained for 30 min with hamster T-antiserum (Flow), diluted 1 : 10 in phosphate-buffered saline (PBS), and rinsed for 30 min in PBS. They were then incubated for 30 min at 37 °C after addition of 5 drops of fluorescein-conjugated rabbit anti-hamster IgG, diluted 1 : 10 in PBS, were added to each coverslip. The coverslips were then washed in PBS, mounted on glass slides with 1 drop of PBS-glycerine 1 : 10, *p*H 7.4, and examined with a Leitz fluorescence microscope. Each point represents the average of two experiments.

We studied T-antigen formation in WT SV40 and *1501* productively infected TC7 cells using a modification of the indirect immunofluorescence technique described by Pope and Rowe[19]. After virion adsorption at 37 °C for 60 min, T-antigen development was monitored in WT SV40-infected and *1501*-infected cells incubated at 37 °C and 41 °C (Fig. 1). More than 90% of the WT SV40-infected cells at both temperatures and *1501*-infected cells at 37 °C showed positive T-antigen fluorescence, but less than 10% mutant-infected cells were T-positive at 41 °C.

We also studied the effects of elevated temperature on T-antigen expression in WT SV40-transformed and *1501*-transformed hamster kidney cells. The histories and characteristics of T8-AP1, a hamster kidney cell line transformed by WT SV40, and HK10-c2 (*in*(ts)-1501), a twice-cloned, heat-inducible hamster kidney cell line transformed by 1501, were described previously[3]. Because Robb[20] showed that WT SV40-transformed and ts*D*-transformed 3T3 cells have reduced T-antigen expression at nongrowing saturation densities, we monitored T-antigen in subconfluent (60–70%) cultures. Unlike WT SV40-transformed cells, the *1501*-transformed cells had decreased T-antigen expression at the elevated temperature (Fig. 2). Increasing activation of infectious virus was observed in parallel cultures of *1501*-transformed cells at 41 °C but not at 37 °C nor in WT SV40-transformed cells at either temperature.

Table 2 Determination of T-antigen in cell extracts by antibody absorption

Incubation mixture	Titre
Buffer	1 : 8
WT SV40-transformed cell (37 °C)	0
WT SV40-transformed cell (41 °C)	0
1501-transformed cell (37 °C)	0
1501-transformed cell (41 °C)	1 : 8

Subconfluent cultures were grown at 37 °C and 41 °C for 48 h. T-antigen was extracted by the method of Ahmad-Zadeh *et al.*[27]. Cells were suspended at concentrations of 10^7–10^8 in 5 ml of extraction buffer (2.5 mM Tris–HCl, *p*H 7.4, 0.5M LiCl, 1 mM EDTA), sonicated three times for 15 s, and immediately centrifuged for 30 min at 30,000*g* and 4 °C. The supernatant was removed and used as the antigen. Extracts were adjusted to the same protein concentration (20 mg ml^{-1}). Antigen was assayed by the ability of the cell extract to absorb antibody to T-antigen. A modification of the method of Alspaugh *et al.*[28] was used. Equal volumes of anti-T serum and the cell extracts were incubated at 37 °C for 60 min, then at 4 °C for 16 h. Incubation mixtures were then serially diluted and assayed for unbound T-antibody by indirect immunofluorescence on WT SV40-transformed cells. The titre represents the highest dilution of the incubation mixture that still gave the chracteristic nuclear speckling of T-antigen-positive cells.

The presence of T-antigen was also assayed by using antigen extracts from each cell line grown at 37 or 41 °C to absorb the the T-antibody from SV40 T-antiserum before staining for immunofluorescence (Table 2). If T-antigen was present in the extract, it would bind to the T-antibody and prevent immunofluorescent staining of WT SV40-transformed cells. The immunofluorescence titre was decreased eightfold or greater by the extracts from *1501*-transformed cells grown at 37 °C and

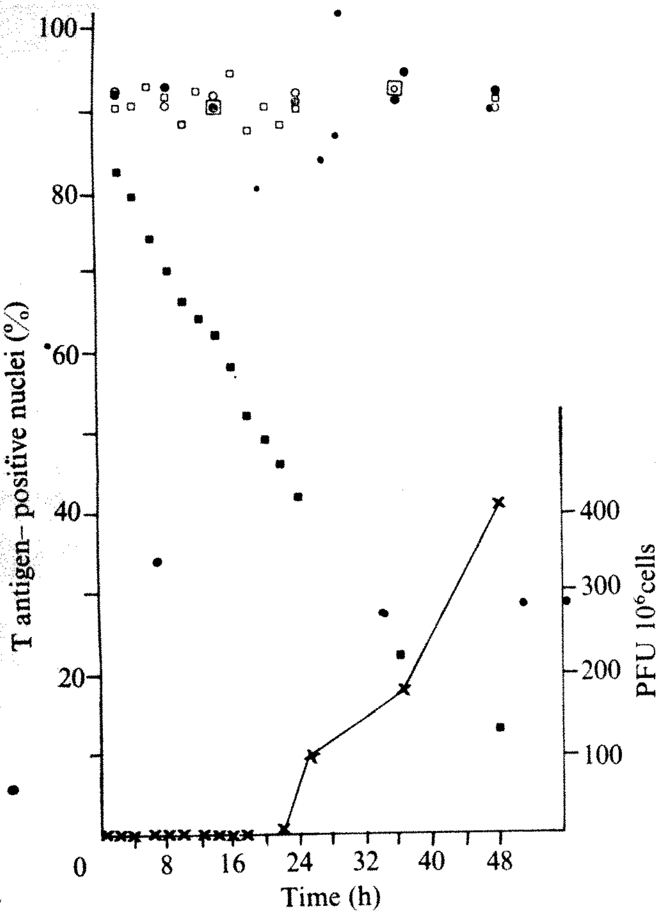

Fig. 2 All cell lines were maintained at 37 °C for 24 h after passage. At time zero, WT-transformed cells were incubated at 37 °C (○) and 41 °C (●). Parallel cultures of *in*(ts)-1501-transformed cells were incubated at 37 °C (□) and 41 °C (■). Infectious virus (×) activated at 41 °C in *1501*-transformed cells was assayed as plaque-forming units (PFU). The percentage of T-positive cells was determined as described in the legend of Fig. 1. The cell viability, measured by Trypan blue exclusion, remained more than 92% throughout the experiment. *in*(ts)-1501-transformed cells exhibited a characteristic decline in viability after 96 h at 41 °C.

from T8-AP1 grown at either temperature; however, the extract from *1501*-transformed cells grown at 41 °C did not absorb the antibodies in the T-antiserum, indicating that T-antigen is not present in these conditions.

Thermal lability of the *1501* T-antigen extract was assayed by heating aliquots of the extract for various times at 50 °C. Using the antibody-absorption technique described in Table 2, we found that T-antigen was completely inactivated after 30 min at 50 °C.

We tested for the reversability of the apparent loss of T-antigen in HK10-c2(*in*(ts)-1501) cells at the nonconditional temperature. Subconfluent cultures of cells, maintained at 41 °C for 24 h, were shifted to 37 °C. The percentage of T-antigen-positive nuclei gradually increased from 38% after 24 h at 41 °C to 90–95% after incubation at 37 °C for 3 d. Cell viability, measured by trypan blue exclusion, remained greater than 90% throughout the experiment.

These results suggest that the *in* gene affects the heat lability of T-antigen and that certain antigenic determinants of T-antigen may be required for the maintenance of SV40 DNA integration. Furthermore, induction of host-cell DNA synthesis and T-antigen are separate early viral functions. We postulate that one function of the SV40 T-antigen may be to interact with specific recognition sites on either viral or cellular DNA, selectively regulating viral DNA integration and/or late viral DNA transcription. Consistent with this hypothesis are the findings of Carrol *et al.*[21], who demonstrated that SV40 T-antigen binds strongly to double-stranded DNA with two different salt-concentration-dependent affinities, and of Reed *et al.*[22], who showed that T-antigen can bind selectively to SV40 DNA at or near the origin of SV40 DNA replication.

We must reconcile our observations with findings that the T-antigen is the *A*-gene protein[13,16,17,23]. The thermal lability of T-antigen from *1501*-transformed cells indicates a relationship between the *1501* and ts*A* mutants. The most likely explanation is that the *in* and *A* cistrons may code for a multifunctional protein, such as that found in the his*B* gene in *Salmonella typhimurium*[24] or the aspartokinase I-homoserine dehydrogenase I gene of *E. coli*[25], in which two activities can be altered independently. Other explanations are possible, however. A test of the hypothesis of T-antigen pleiotropy will necessitate the isolation and characterisation of the mutant T-antigen and study of its interaction with DNA.

We thank Emmett Johnson, James A. Robb, Mary Weiss, Richard O'Callaghan and Charles Chapman for helpful discussions, George Khoury and Paul Black for antiserum, and Muriel Murphy for preparing the typescript.

Contiguity to male foetuses affects morphology and behaviour of female mice

DURING studies on the role of gonadal hormones in aggressive behaviour of mice, we observed large variations in both the morphology and behaviour of females. At birth, variation was evident with respect to the principal external sex-differentiating marker—distance between the anus and the genitals, with some females being difficult to distinguish from males. Moreover, a significant proportion of females, upon reaching adulthood, were more responsive to androgen than others, exhibiting male-like aggressive behaviour more quickly following its administration. These observations led to the speculation that a certain proportion of females had been masculinised naturally during prenatal development. We present here data which show that such masculinisation does occur and that it is mediated by proximity to male foetuses.

That prenatal masculinisation of the female can occur naturally in the rodent was suggested by the data of Clemens[1]. Based upon a relatively small sample, especially with respect to that used to assess behaviour, it was reported that female rats, contiguous to male foetuses during gestation, had larger ano-genital distances at delivery and displayed more male sex behaviour in response to androgen treatment given in adulthood than did females that had not been in such close proximity to males. It was suggested that masculinisation of the female was mediated by exposure to androgen from the foetal testis. We now present data which show conclusively that, in mice, the position of the female in the uterus relative to that of males determines the extent to which the female is both morphologically and behaviourally masculinised.

Thirty-eight 60–70 d-old nulliparous Rockland–Swiss albino mice, housed separately in 11 × 7 × 5-inch translucent cages, were provided with food and water in excess and kept on a 12 h light/12 h dark cycle with lights on at 0600 h. An adult male was introduced into each female's cage and removed on the discovery of a copulatory plug. Pregnancy was interrupted at 2000 h on day 18 of gestation (delivery normally occurs between 0100 and 0500 h on day 19 of gestation, taking the day of coitus as day 0 of pregnancy) and the foetuses were delivered surgically. The adult was killed by cervical dislocation, the uterine horns were exposed, and the foetuses expelled with their position in the uterus relative to other foetuses noted. They were cleaned with saline and ano-genital distances measured. The females then were gonadectomised under ether anaesthesia and marked by injecting India ink into the footpads. The sequence of marks identified the position of a foetus with respect to the sex of the foetuses on either side. Males from 10 of the pregnant animals also were gonadectomised and marked. The animals then were fostered in same-sex groups of four or five to mothers that had delivered within the preceding 24 h and whose young had been removed.

The animals were weaned on day 21 of life and kept in their foster-littermate groups until day 60, when they were implanted subcutaneously with a 10-mm Silastic capsule containing 5 mg testosterone (T) and housed singly. Testing for aggression, begun 2 d later, was conducted on alternate days for a maximum of 50 d (25 tests) or until a fight occurred. Testing consisted of placing an adult olfactory bulbectomised male into the cage of each female and leaving it there for 10 min. Olfactory bulbectomised males, although eliciting aggression comparable to that of intact males, neither initiate fights nor respond to attack by retaliating. Thus, they provide a relatively constant stimulus for tests of aggression[2]. A fight was scored when an animal chased and bit the stimulus male. The number of days of T exposure required to induce aggression was recorded. Although the administration of T to non-neonatally androgen-exposed adult mice will produce aggression, animals exposed to T during early development will fight sooner following the start of T exposure in adulthood[3].

Fifty-two females survived to adulthood: 15 had been situated between two male foetuses (group 2M), 28 next to one male foetus (group 1M), and nine contiguous with no male foetus (group 0M). Nineteen males also survived to adulthood. An analysis of variance of the ano-genital distances of the females recorded at delivery yielded a significant uterine position effect ($P > 0.001$) (see Fig. 1). Individual comparisons using Duncan's test[4] with α at 0.05 showed that animals of group 2M had significantly larger ano-genital distances than did those of group 1M and 0M. The latter two groups did not differ from one another. As it was possible that the absolute number of males in the uterus rather than contiguity to males mediated the effect upon ano-genital distance, an analysis of covariance was performed with the number of males per uterus serving as the covariate. This analysis revealed that ano-genital distance did not vary as a function of the absolute number of males present in a uterus. The mean ano-genital distance for each of the 3 groups of females was then compared to the mean for the males using Dunnett's test[4] to compare means to a standard with α at 0.05. Males had a significantly larger mean ano-genital distance than did any of the groups of females.

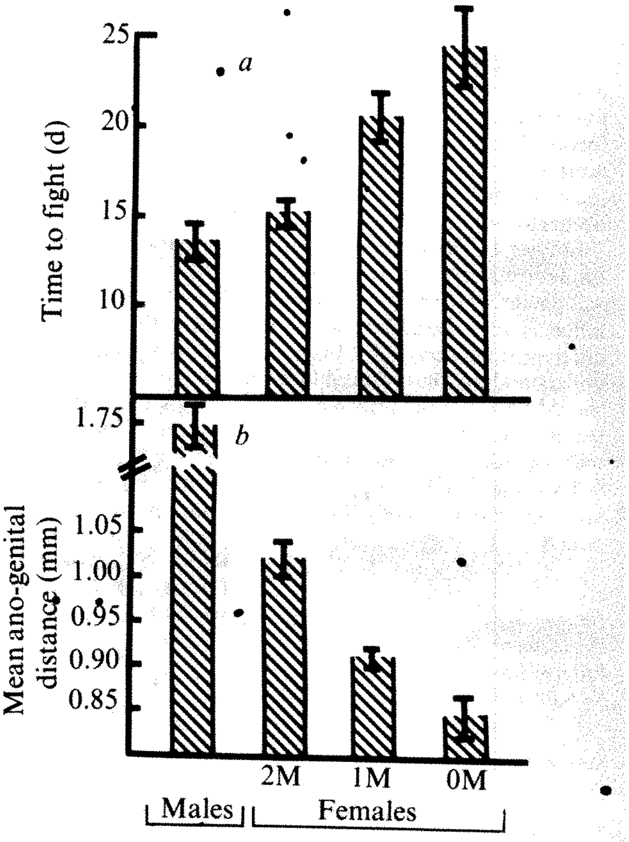

Fig. 1 *a*, Number of days to fight following the start of testosterone exposure of male and female mice, and *b*, ano-genital distance of delivery. Females were located in the uterus either between two male foetuses (2M), next to one male (1M), or contiguous to no male foetus (0M). All animals were delivered approximately 3.5 h prematurely and gonadectomised at that time. Data are means ± s.e.m.

As ano-genital distance varied as a function of contiguity to male foetuses, it was predicted that the females of the most morphologically masculinised group (2M), with the largest ano-genital distance, would require the shortest period of exposure to T in order to establish aggression. Conversely, females of the least masculinised group (0M) would require the longest exposure period. These predictions were supported. Females of Group 2M did require a significantly shorter period of exposure to T to exhibit aggression than did animals of group 0M. Females of group 1M were intermediate, not differing significantly from the animals of group 2M and 0M. The males did not differ significantly from the females of group 2M and 1M but did require a shorter exposure period to T than animals of group 0M. Finally, collapsing across the three groups of females, a significant negative correlation ($r = -0.30$, $P < 0.05$) was obtained between ano-genital distance at delivery and the number of days of T exposure required to induce aggression.

The variability normally exhibited by female mice in morphology and behaviour can thus be accounted for, in part, by the position of the female in the uterus relative to that of males. Females situated between two male foetuses were masculinised as indicated by larger ano-genital distance and increased responsiveness to the aggression-promoting property of T. Females contiguous with one male were masculinised with respect to behavioural responsivity to T but not morphologically. Female rat foetuses contiguous to a male foetus are heavier[5], so the large ano-genital distance of female mice situated between two males might have been due to the fact that these females were heavier than the others. This is not the case, however, as there were no differences in body weight between the three groups of females. It also is possible that the effect is specific only to the Rockland–Swiss strain. Although data on the effect of uterine position on responsiveness to T are not available, we have found that uterine position does significantly influence ano–genital distance in the CF-1 strain.

The foetal mouse testis begins to secrete androgen on day 12.5 of gestation[6], and tritiated T injected into the amniotic fluid of a rat foetus passes by diffusion into the amniotic fluid of a contiguous foetus[7]. This indicates, therefore, that the effect upon female morphology and behaviour of proximate male foetus may be mediated by exposure to androgen and that its transmittal occurs locally at the level of adjacent amniotic membranes.

Studies of the difference between disparate groups provide fundamental information concerning factors which affect development, as in the use of males and females to demonstrate the influence of gonadal hormones. Identifying the determinants of differences between individuals, however, is a prime requisite for understanding the variability within a group and, therefore, should be one of the principal concerns of psychology. Our study seems to identify a contributory factor underlying the development of individual differences.

Mutagenicity and toxicity of visible fluorescent light to cultured mammalian cells

MANY cultured mammalian cells are characterised by karyotypic instability, high rates of spontaneous transformation and high frequencies of background mutation. The toxicity of visible light for mammalian cells[1–4] is usually attributed to photochemical reactions between light and the culture medium, and riboflavin, tryptophan and tyrosine are often thought to mediate this toxicity[1–3]. Light has been shown to produce strand breaks in DNA[5,6]. Because many tissue culture operations are conducted under fluorescent light, we have investigated whether the toxicity and DNA strand-breaking activity of light are accompanied by mutagenicity. We report here that this is the case.

The toxicity of fluorescent light for V-79 Chinese hamster lung (CHL) cells incubated during irradiation in either complete α-MEM (CM) or balanced saline solution (BSS) is shown in Fig. 1. Both survival curves are slightly shouldered, implying a saturable repair process. Evidently light is toxic to these cells whether they are irradiated in CM or BSS, although toxicity after 2 h of irradiation is greater for cells in CM. This result is in contrast to those of Stoien and Wang[2], who found no killing of human D98/AH2 cells irradiated with fluorescent and near-ultraviolet light in phosphate-buffered saline.

We tested whether pre-irradiation of CM, toxic for some cells[2,7], would kill V-79 cells subsequently incubated in it. Table 1 shows that medium that has been pre-irradiated for 3 h in the same conditions as the cells does not reduce the colony-forming ability of V-79 cells. The final colony diameter after 1 week of growth, however, was decreased and the cellular morphology was altered by pre-irradiated CM (Table 1).

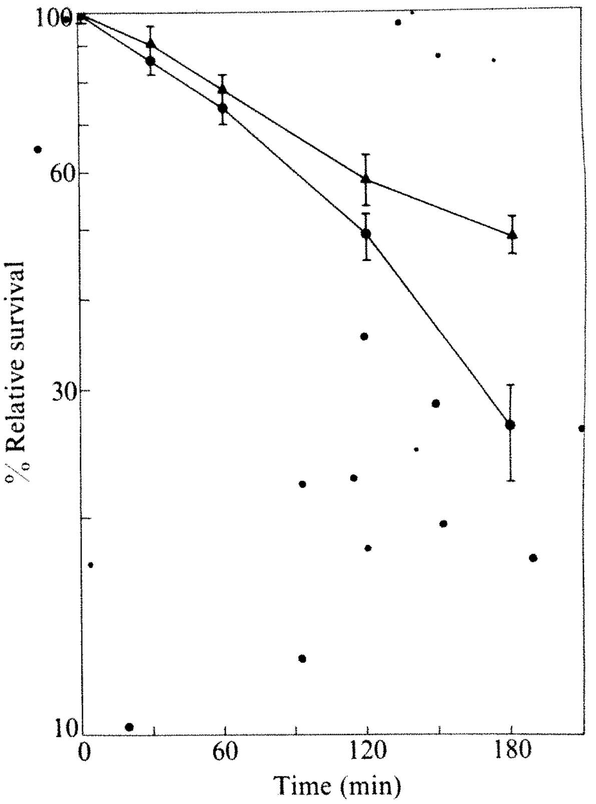

Fig.1 Toxicity of fluorescent light to V-79 CHL cells incubated in medium or saline. Three hundred exponentially growing V-79 cells were inoculated into 10 ml of CM (α-MEM[8], minus purines and pyrimidines, containing 5% FCS (Flow Laboratories) and 25 mM HEPES in 100-mm Falcon plastic Petri dishes). The cells were allowed to attach to the dishes at 37 °C in a 7.5% CO$_2$/air incubator. Four hours after inoculation, some plates were rinsed three times with BSS (without phenol red) containing 25 mM HEPES and incubated at 4 °C in the same solution. Plates containing CM or BSS were placed in a room at 4 °C and irradiated with fluorescent light for the times indicated. All plates were kept in the cold room for 3.5 h. Irradiation was by four Sylvania Cool White F15T8-CW bulbs held in two desk lamps. The bulbs were 8 cm above the surface of the cells and the intensity of illumination at that distance was 1,700 foot candles as measured with a Weston Foot Candle Meter Model 614. Irradiation was from above through both the plastic dish top and the overlying medium. The temperature in the dishes never exceeded 10 °C. After 1 week of incubation, the colonies were rinsed with BSS, fixed in methanol for 10 min, stained with Giemsa and counted. A colony was defined as more than 64 cells in close proximity. The plating efficiency of the unirradiated chilled control cells in CM was $86\pm3\%$ (six plates) and in BSS it was $82\pm7\%$ (six plates). The number of colonies surviving after light treatment is normalised to the survival of the controls. The mean relative survival $\pm$ % s.d. is plotted. When the standard deviations overlap, the upper and lower limit bars are for the upper and lower points, respectively: ●, cells irradiated in CM; ▲, cells irradiated in BSS.

These data suggest that the basis of the toxicity of fluorescent light to V-79 cells is primarily a direct action of light on the cells themselves, because toxicity occurs in BSS alone (Fig. 1) and because preirradiated medium does not reduce colony-forming ability (Table 1). Nevertheless, complete medium can potentiate the action of light as shown by the slightly greater killing of cells in medium compared with saline (Fig. 1) and the reduced colony diameter and altered cell morphology caused by pre-irradiated CM (Table 1).

The effect of fluorescent light on the frequency of mutants in V-79 cells is shown in Fig. 2. Resistance to 6-thioguanine was used as a marker for inactive hypoxanthine-guanine phosphoribosyl transferase and as an assay for mutant colonies. The method is described in the legend to Fig. 2. The number of 6-thioguanine-resistant, presumably mutant, colonies increased linearly as the time of exposure to cool white fluorescent light

Table 1 Toxicity of pre-irradiated medium to V-79 Cells

Time of pre-irradiation (h)	% Colony formation relative to controls	Mean colony diameter (mm)	Cellular morphology
0	100±7	0.96±0.38	Normal
1.3	101±5	0.66±0.29	Abnormal
3.0	99±3	0.57±0.36	Abnormal

Three hundred V-79 cells were plated in 100-mM Petri plates as described in the legend to Fig. 1, except that no HEPES was included in the medium. Fifty ml of CM in a closed Corning 150-cm² flask in a room at 4 °C were irradiated with the fluorescent lights described in Fig. 1. To test the effect of irradiating CM on cloning efficiency, the original seeding medium was replaced after 4 h with the same volume of irradiated medium. After 7 d of incubation, colonies were fixed with methanol and stained with Giemsa. The plating efficiency of the controls was 78±3%. The values shown represent the mean survival relative to the controls ± s.d. for three plates. The mean colony diameter and s.d. were determined by measuring 50 colonies on three plates. The differences between the light-treated and untreated means are significant by a *t* test with a *P* value of 0.01. Cellular morphology was examined along the edges of clones with a phase contrast microscope. Morphology was considered abnormal if the cytoplasm was elongated and vacuolated in many clones.

increased (Fig. 2). After 3 h of irradiation in α-MEM the frequency of mutants was 166 times greater than in unirradiated controls. The single point above the line in Fig. 2 shows that after 3 h the frequency of mutants was greater for cells irradiated in BSS than for cells irradiated in CM. This is confirmed by the data in Table 2, which show that fluorescent light was 1.9 times more mutagenic for cells irradiated for 1 h in BSS than for cells irradiated for 1 h in CM.

If 50 ml of CM was used as a filter in a 150-cm² flask placed over the cells in another 150-cm² flask containing 50 ml of BSS, the frequency of mutants was not significantly changed from cells irradiated in CM without a filter (Table 2). This experiment implies that irradiation in CM is less mutagenic than irradiation in BSS because CM is partially filtering mutagenic portions of the fluorescent lamp emission.

Assuming that a linear dose–response relationship exists for mutagenicity with shorter exposures to light (Fig. 2), it can be calculated from the data presented here that a 1-h exposure to the incident fluorescent light in our tissue culture room (60 foot candles) will double the frequency of mutants in V-79 cells. In most laboratories this amount of exposure or more would occur intermittently on a daily basis. For example, we have found that after killing pre-existing 6-thioguanine-resistant mutants with HAT medium, the frequency of spontaneous mutants will increase progressively during a period of weeks (our unpublished results). This observation might be explained by the mutagenic action of the fluorescent light in our tissue culture hood and culture room that causes the frequency of mutants to increase with each exposure. Therefore it is possible that other genetic instabilities seen in cultured cells, such as malignant and karyotypic alterations, might be accounted for in part by the action of fluorescent light on the cellular DNA.

Table 2 Mutagenicity of fluorescent light for cells irradiated in CM or BSS

Medium	Filter	Time of irradiation (h)	Frequency of mutants* $\times 10^{-6}$
CM	—	0	1.42± 0.21
CM	—	1	38.6± 6.4
BSS	—	1	71.9±12.4
BSS	50 ml CM	1	34.1± 5.1

The frequency of mutants was determined as described for Fig. 2.
*Mean value±s.d. of three determinations.

From the data presented here, we conclude that exposure to fluorescent light should be limited during virtually any study with cultured cells. It is important that all exposure to light in our work was through the plastic tops of the culture vessels. Plastic absorbs more than 99% of any ultraviolet wavelengths less than 295 nm, so that the active wavelengths are presumably

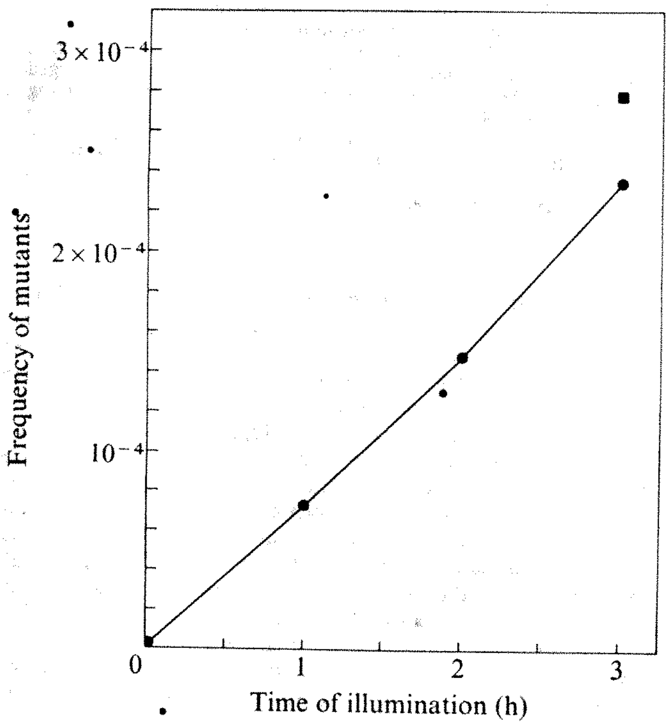

Fig. 2 Mutagenicity of fluorescent light to V-79 CHL cells incubated in CM or BSS. The frequency of mutants in V-79 cells after various treatments was measured by a modification of a method described by Myhr and DiPaolo[9]. Briefly, cells were cultured in α-MEM with 5% FCS at 2.5×10^5 cells per 150-cm² Corning plastic flask or per Falcon 15-cm Petri dish. Stock cells were subcultured every Monday and Thursday. On Thursday of each week, 2.5×10^5 stock cells were placed in HAT medium (CM containing 10^{-5}M hypoxanthine, 3.2×10^{-6}M aminopterin and 5×10^{-6}M thymidine,) and subcultured into HAT medium on the next Monday. On the following Thursday, having been in HAT medium for 1 week, cells were trypsinised and incubated in HT medium (CM containing 10^{-5}M hypoxanthine and 5×10^{-6}M thymidine). On Friday the medium was changed to CM; on Monday HAT-HT-CM cells were inoculated (10^6 cells each) into 150-cm² flasks in 50 ml of CM. On Wednesday there were usually 3×10^7 cells in log phase in each flask. One flask was trypsinised, and the cells were inoculated into 100-mm Petri dishes to determine the toxicity of the light treatment. The other flasks were irradiated in a room at 4 °C with fluorescent lights as described for Fig. 1. All flasks including controls were pre-incubated at 4 °C for 15 min before irradiation and remained in the cold room for 3.5 h until irradiation was complete. After irradiation the medium was removed and replaced with fresh CM at 37 °C. Two days later cells from the treated and control flasks were subcultured into 150-cm² flasks at 2×10^6 cells per flask to allow further time for mutations to be expressed. The flasks were incubated for at least another 3 d, until cultures were about to become confluent (at about 5–10× 10^7 cells) and had undergone at least four population doublings. If the cultures were not approaching confluency within 5 d of treatment, they were incubated until confluency was almost achieved. The fraction of mutant cells in the population at this time was assayed by seeding a total of 2.7×10^6 treated and recovered cells among nine 100-mm Petri dishes (3×10^5 cells per dish), in 15 ml of CM containing 6-thioguanine (11 μg ml⁻¹). At the same time, the plating efficiency of these cells was determined by seeding 300 cells each in six 100-mm Petri dishes in CM. Plates were incubated for 1 week before fixing and staining. A colony was defined as containing more than 64 cells. The data for the cultures incubated in CM during exposure to light were analysed statistically using linear regression by the method of least squares. The coefficient of determination for these data is 0.9975; this value is so close to 1.0 that these data can be said to fit a linear equation of the form $y = a_1x + a_0$, where a_1 and a_0 are constants. ■, Culture incubated in BSS during 3 h exposure to light; ●, cultures incubated in CM during 1, 2 or 3 h exposures to light.

longer than 295 nm. Exposure to excessive fluorescent light might produce artefacts in studies of *in vitro* toxicity, mutation, transformation, chromosome variation, ageing, effects of radiation, drug interactions and biochemistry. Whether or not our findings with V-79 Chinese hamster cells will extend to human and other mammalian cells remains to be determined. If human cells are also caused to mutate by fluorescent light, then the advisability of limiting human exposure to fluorescent light should be considered.

Skin fibroblasts from a D-deletion type retinoblastoma patient are abnormally X-ray sensitive

RETINOBLASTOMA is a rare malignant eye tumour which appears spontaneously or occurs in genetically predisposed persons[1-3]. The latter group is composed of patients who inherit the tumour with a dominant mode of transmission (80–90% penetrance) (referred to as the familial type) or those who bear a deletion in the long arm of chromosome 13 (13q-) (referred to as the D-deletion type). When this deletion is present, it is observed in many somatic cells and is often associated with structural defects such as microcephaly, micropthalmia and several skeletal and genitourinary abnormalities[3,4]. Survivors of the genetic forms of retinoblastoma have an increased risk for the development of cancers at other sites, while patients who survive the sporadic type do not[2-6]. A single genetic locus is unlikely to predispose many somatic cells to tumour formation unless a fundamental molecular defect—for example, related to DNA repair—is present. To investigate this hypothesis, we have examined the *in vitro* X-ray sensitivity of skin fibroblast strains derived from three retinoblastoma patients—a pair of twins with the familial type accompanied by no gross chromosome abnormalities, and a patient with the D-deletion type. We also used two normal fibroblast strains and a strain from a patient with ataxia telangiectasia. We found that the strain derived from the D-deletion retinoblastoma patient was significantly more radiosensitive than the two normal strains, but not as sensitive as that from the ataxia patient.

Figure 1 shows the X-ray survival curves obtained with skin fibroblasts derived from both a normal individual and a patient with a D-deletion type retinoblastoma[3]. Also included for comparison is a survival curve for cells from a patient with ataxia telangiectasia; this autosomal recessive disease is associated with marked cellular radiosensitivity *in vitro*[7], presumably due to an X-ray repair defect[8]. As Fig. 1 shows, the retinoblastoma cells were significantly more sensitive to killing by X rays than were the normal fibroblasts, but not as sensitive as the ataxia cells.

Table 1 presents a comparison of X-ray survival curve parameters for the three retinoblastoma cell strains, two normal strains and the ataxia strain. The experiments were all performed within 10 weeks using the same lot of serum. Some variations were seen in survival parameters with different serum lots, but the sensitivities of these strains relative to each other remained constant. In nine experiments, including those in Table 1, the D_0 (inverse of the slope) for GM1142 ranged from 70 to 98 rad. The two familial retinoblastoma strains showed radiosensitivities intermediate between the D-deletion retinoblastoma strain and the normal strains, but it is not clear whether these retinoblastoma strains are significantly more radiosensitive than normal controls. As we have found before[9], the n values of the survival curves bore no relationship to radiosensitivity as measured by D_0. We have no explanation for the possible differences in n among the cell strains in Table 1. In preliminary experiments, all three retinoblastoma strains appeared normally sensitive to 254 nm ultraviolet irradiation.

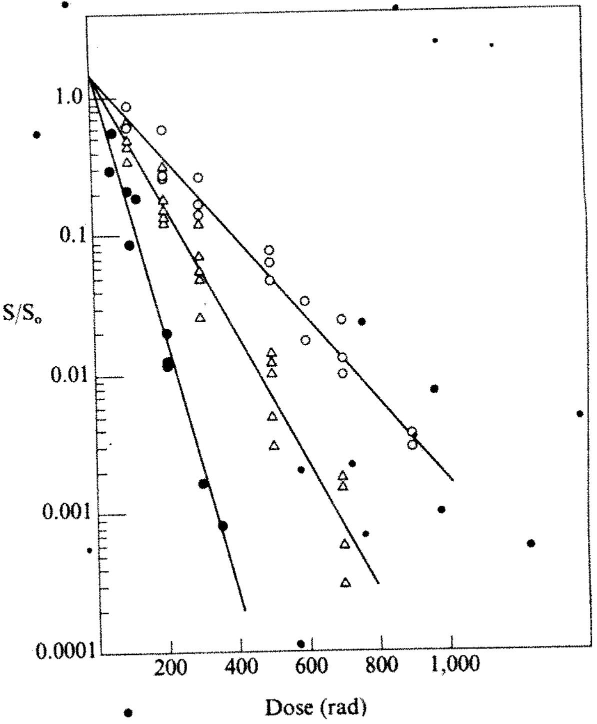

Fig. 1 X-ray survival curves for exponentially growing cultures. △, GM1142, skin fibroblasts from a female retinoblastoma patient with a deletion in the long arm of chromosome 13 (46, XX (13q-)); ●, CRL1343, skin fibroblasts from a patient with ataxia telangiectasia; ○, Li106, normal skin fibroblasts. Cultures were maintained at 37 °C in Eagle's minimal essential medium (Gibco F-15) supplemented with 15% foetal calf serum (Flow) D-glucose (900 mg l^{-1}), sodium pyruvate (0.66 mg l^{-1}) and Aureomycin (50µg ml^{-1}, Lederle) in a 5% CO_2 atmosphere. Cells from each strain were studied at similar passage levels in culture (ranging from 4th to 22nd mean population doubling). For experiments, exponentially growing cells were detached with 0.25% trypsin and seeded at appropriate numbers into 100-mm plastic Petri dishes. Dishes were X-irradiated 18 h later using a 220 kVp GE Maximar unit operated at 15 mA and yielding a dose rate of 80 rad min^{-1}. Dishes were returned to the incubator, the medium was changed after 7 d and the colonies were fixed and stained after 14 d. Cloning efficiencies ranged from 1 to 16%; radiosensitivity was not related to cloning efficiency (Table 1), and previous results have shown no relationship between cloning efficiency and survival curve parameters in several strains of human skin fibroblasts[9]. Points represent the average of triplicate plates. Curves represent a least squares linear regression analysis of the points shown. S/S₀, surviving fraction.

As more fibroblast strains from D-deletion retinoblastoma patients become available, it will be interesting to examine their responses to radiation in order to establish whether the radiosensitivity of the retinoblastoma strain described here relates to the fundamental disease process itself or to its

Table 1 X-ray sensitivities of human diploid fibroblast strains

Strain (source)	Clinical classification	Age/sex of donor	No. of experiments	Cloning efficiency	n*	D_o*
GM1142 (IMR)	Retinoblastoma D-deletion type	2 yr/F	6	0.7–6.5%	1.41±0.3	94±5
GM1131 (IMR)	Retinoblastoma familial type	9 mon/F	3	3.0–16.5%	0.87±0.09	132±4
GM1123 (IMR)	Retinoblastoma familial type (twin of GM1131)	9 mon/F	3	1.2–12.4%	1.03±0.1	121±4

association with an abnormal karyotype involving a specific chromosomal region and perhaps a specific gene product. Patients with familial retinoblastoma may bear a much smaller deletion not detectable by available karyotypic and banding methods.

It is tempting to speculate that a specific X-ray repair function is governed by a portion of chromosome 13. Thus the predisposition to cancer in these patients might be related to a fundamental defect in a particular DNA repair system, analogous to the relationship between a deficiency in ultraviolet light repair and the predisposition to skin tumours in patients with xeroderma pigmentosum[10].

We conclude that skin fibroblasts derived from a patient with the D-deletion variant of retinoblastoma are abnormally radiosensitive. Perhaps future investigations will delineate a specific defect in molecular repair of DNA that will explain the predisposition of these patients to develop second primary tumours.

We thank Dr Warren Nichols for helpful discussions. This work was supported by grants from the NCI and NIEHS.

Inhibition by sera and soluble antigens of T-cell-mediated cytotoxicity against leukaemia-associated antigens

INTEREST in the regulation of T-cell-mediated cytotoxicity by the major histocompatibility complex (*MHC*) genes stems from the discovery of (1) an H–2 restriction of T-cell-mediated cytotoxicity, that is sensitising cells, effector cells and target cells need to be syngeneic at the *H-2* locus, especially at the D and or K regions of the MHC[1–5] for effective killing and (2) inhibition of T-cell-mediated cytotoxic reactions against syngeneic tumours with alloantibodies to H–2 antigens specific for the tumour cells[6,7]. Different origins have been proposed for the tumour-associated antigens (TAA), and the most favourable model is a modified H–2 antigen or an adaptor–antigen complex[4–7]. This issue has important implications for tumour immunology, and so we have evaluated the validity of the inhibition of cytotoxicity by serum at the effector phase level; investigated afferent interference by serum of the cell-mediated cytotoxic response, and studied the inhibition of cell-mediated cytotoxic reactions with soluble antigens. We report here that there is a lack of H–2 restriction of T-cell-mediated cytotoxicity to TAA, and that TAA seems to differ from H–2 antigens. This implies that T-cell recognition is not entirely regulated by the *MHC* genes.

A 20-h ^{125}IUdR release assay (IRA) (ref. 8) was used to measure cell-mediated cytotoxic response to FBL-3 (ref. 9), a syngeneic Friend virus-induced lymphocytic leukaemia in C57BL/6 (B6) mice. The cytotoxic reactions were found to be primarily directed against the Friend Moloney-Rauscher (FMR) leukaemia-associated antigens[10–12]. Both the induction phase and the effector phase of these cytotoxic reactions were entirely T-cell-dependent. Pretreatment of the responding cells[10] or the effector cells[11,12] with anti-θ antibody plus complement eliminated cytotoxicity. Furthermore, removal of adherent cells and macrophages by passage of the effector cells through a rayon column or incubation in a Petri dish did not affect the level of cytotoxicity[11,12]. Thus the reactions were apparently not macrophage-mediated. When various antisera and normal sera were used to study their effects on these cytotoxic reactions (Table 1), we found that effector cells which were generated in B6 mice (H–2^b) by immunisation with syngeneic FBL-3 cells killed both the syngeneic target FBL-3 and an allogeneic target HFL/d-tc, a non-producer line of Friend virus-induced leukaemia in BALB/c (H–2^d) mice[13]. In other experiments, effective killing of FBL-3 and HFL/d-tc cells could also be achieved by lymphocytes obtained in BALB/c mice which were immunised with syngeneic HFL/d-tc cells[14]. These lymphocytes gave even higher levels of cytotoxicity against the allogeneic target FBL-3 than against the syngeneic target HFL/d-tc. In our experiment, an alloantiserum with the appropriate specificity, and the syngeneic serum produced against FBL-3 both inhibited cytotoxicity. In addition normal mouse serum (NMS) gave inhibition against FBL-3 targets.

If NMS or normal rabbit serum were used as a baseline for calculations of cytotoxicity, various other sera, for example, anti-FBS, which bound to the foetal bovine serum coated on the surface of target cells and rabbit anti-mouse cell serum, also inhibited the reactions against both FBL-3 and HFL/d-tc. Anti-Ia, and rabbit anti-mouse Ig, inhibited the reaction against FBL-3. None of the last four sera in Table 1 should contain antibody against H–2 antigens. Thus, it seems that any antibodies that bind to the cell surface can interfere with the cytotoxic reactions, perhaps by steric hindrance. This conclusion was also suggested by the following results. (1) Pretreatment of either the target cells or effector cells

Table 1 Inhibition of cell-mediated cytotoxic reactions with sera

Serum	FBL-3 Net % lysis	FBL-3 Net % lysis(s)	FBL-3 P	HFL/d-tc Net % lysis	HFL/d-tc Net % lysis(s)	HFL/d-tc P
None	49			18		
NMS	32			15		
Anti-H-2^b	4	−28	< 0.01	17	2

Anti-FBL-3	19	−13	< 0.01	10	−5	< 0.01
Anti-FBS	14	−18	< 0.01	7	−7	< 0.01
Anti-Ia	27	−5	< 0.05	ND		
NRS	46			18		
RAM	−5	−51	< 0.01	8	−10	< 0.01
RAG	10	−36	< 0.01	23	5	

^{125}IUdR release assay was performed in Microtest II plates. E/T (ratio of effector : target cells) = 500/1, incubation time was 20 h. Effector cells were the pooled lymph node and spleen cells obtained from B6 mice immunised by subcutaneous inoculation of 5 × 10^6 FBL-3 cells 10 d before assay. Various sera were added to the test wells at final dilutions of 1/5. NMS, normal mouse serum. Anti-H-2^b was from BALB/c immunised with B6 skin grafts and spleen cells. Anti-H-2^d was from B6 immunised with BALB/c skin graft and spleen cells. Anti-FBL-3, B6 immunised with FBL-3. Anti-FBS, B6 immunised with foetal bovine serum. Anti-Ia was from (B10.A ×)F; immunised with B6 spleen, absorbed with B6 tumour EL-4 cells (given by Dr David Sachs, NIH). NRS, normal rabbit serum. RAM was from rabbit immunised with mouse tumour (SV40 tumour mKSA in BALB/c). RAG, rabbit anti-mouse Ig. Net % lysis = (total % lysis obtained with immune lymphocytes) − (total % lysis obtained with normal lymphocytes). Net % lysis(s) = (net % lysis obtained with immune lymphocytes plus antiserum) − (net % lysis obtained with immune lymphocytes plus normal serum). Welch distribution t test was used to determine statistical significance. The results were compared to net percentage of lysis obtained with immune lymphocytes plus normal serum (NMS or NRS).

with antisera for up to 4 h followed by a single wash did not reduce cytotoxicity (data not shown); whereas significant antibody binding to the FBL-3 cells could still be demonstrated after five washes (Fig. 1). This indicates that excess antiserum is needed for inhibition. (2) The degree of inhibition by the serum was in approximate proportion to the amount of the antibody bound to the cell surface (Fig. 1). The isotopic antiglobulin technique (IAT)[15], which measures the amount of antibody bound to the cell surface indicated that the four mouse sera tested gave relative binding to FBL-3 cells in the order anti-H–2^b > anti-FBS > anti-FBL-3 > anti-Ia. When these sera were used in the IRA to assay for their ability to inhibit the cytotoxicity against FBL-3, the same order of effectiveness was found, that is anti-H–2^b was most inhibitory, and anti-Ia was least inhibitory. The anti-H–2^d serum which did not bind to FBL-3 cells also gave no inhibition of cytotoxicity. These results suggest that inhibition by serum need not depend on binding to specific structures, but only on binding to the cell surface, and they are consistent with inhibition being due to non-specific steric hindrance. The effective inhibition of the cytotoxic reaction obtained with rabbit anti-mouse Ig serum supports this possibility although it is not clear why this serum binds to the target cells. In addition, the inhibition of the killing of H–2^d target (HFL/d-tc) by anti-H–2^d seems to be non-specific, because the killer cells were generated by syngeneic immunisation with FBL-3 (H–2^b) and therefore presumably are not directed against any H–2^d-associated antigens.

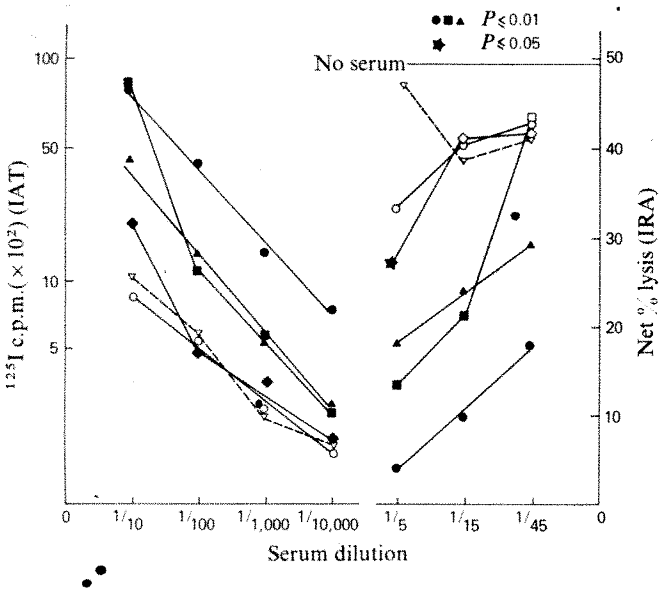

Fig. 1 Reaction of various sera to FBL-3 cells in the isotopic antiglobulin technique (IAT), and their effects on the cell-mediated cytotoxic reaction in the ^{125}IUdR release assay (IRA). In IAT, 0.1-ml samples of sera at various dilutions were incubated with 1 × 10^5 FBL-3 cells, then washed five times, followed by incubation with ^{125}I-labelled goat anti-mouse Ig. They were washed five times, and the radioactivity of the cell pellets were counted in a γ scintillation counter. The relative amounts of antibody bound to the cell surface were indicated as ^{125}I c.p.m. and were relative to that of normal mouse serum (NMS). In IRA, effector cells were obtained from B6 mice immunised with syngeneic tumour FBL-3 and tested against FBL-3 in Microtest II plates with E/T = 500/1 and incubation for 20 h. In this experiment, 0.1-ml samples of sera at various dilutions were added to the test wells to determine their effects on the inhibition of cytotoxicity. The statistics were evaluated by the Welch distribution t test. The results were compared to net percentage of lysis obtained with effector cells with addition of NMS. The mouse sera were the same as for Table 1. ∇, Anti H–2^d; ○, NMS; ★,⧫,◊ anti-Ia; ▲, anti-FBL-3; ■, anti-FBS; ●, anti-H–2^b.

We have shown that specific afferent interference of transplantation immunity to FBL-3 could be produced by pretreatment of the immunising cells with specific anti-tumour antiserum[16]. It follows that if TAA is truly modified H-2, then anti-H-2 antibody should produce similar interference. Therefore various sera were used to determine their effect on the induction of cell-mediated cytotoxic response to FBL-3 in the syngeneic B6 host (Table 2). Only pretreatment with syngeneic anti-FBL-3 serum could specifically reduce the cytotoxic response. Neither anti-H-2^b, nor anti-FBS had any effect, providing further evidence that TAA is not associated with H-2 antigen.

Table 2 Afferent interference of cell-mediated cytotoxic response with sera

Anti-H-2^b	43	20
Anti-FBS	46	23

*1 × 10^5 of 10,000-R X-irradiated FBL-3 cells were incubated with 0.5 ml of undiluted serum at 37 °C for 60 min. Then 1 × 10^4 untreated or serum-treated cells were inoculated intraperitoneally into B6 mice. ^{125}IUdR assay was performed with peritoneal exudate cells 7 d after immunisation.

†$P \leq 0.01$: statistical significance was evaluated by the Welch distribution t test. The results were compared to net percentage of lysis obtained from mice immunised with untreated cells or normal serum-treated cells.

Finally, three different soluble antigens were tested for their effects on the cell-mediated cytotoxic reactions to FBL-3: papain-solubilised FBL-3 membrane antigen, papain-solubilised H–2^b antigen obtained from dissociated B6 spleen cells, and purified viral protein, gp70, prepared from Rauscher virus (given by Dr S. Oroszlan, Flow). The results are summarised in Table 3. Soluble FBL-3 antigen at concentrations as low as 7.5 μg ml^{-1} gave complete inhibition of the cytotoxicity; no inhibition could be obtained with H–2^b antigen even at 50 μg ml^{-1}. The purified gp70 gave 20–30% inhibition at 2.5–12.5 μg ml^{-1}. A mixture of gp70 and H–2^b antigen produced the same inhibition as gp70 alone. These data indicate that unaltered H–2^b antigenic specificities are not present on the receptor site recognised by these cytotoxic lymphocytes although modified H–2^b is not excluded as a target. The viral antigen gp70 is a cytotoxic target, but the fact that partially purified H–2^b does not enhance its inhibitory activity suggests that H–2^b-gp70 complexes are not usually targets, although such a complex might not be obtained easily in a cell-free system. The observation that the soluble FBL-3 preparation can totally inhibit cytotoxicity argues against the existence of H–2–tumour antigen complexes since this material is prepared by papain digestion and such non-covalent complexes would be unlikely to survive such harsh treatment.

Table 3 Inhibition of cell-mediated cytotoxic reactions with soluble antigens

Antigens	Concentration* (μg ml^{-1})	Net % lysis	% Reduction†
None		61	
FBL-3	25.0	−2	103
FBL-3	7.5	5	92
FBL-3	2.5	35	43

H–2^b+gp70	(10+ 2.5)	50	19

^{125}IUdR assay was performed as for Table 1.

*Final concentration of soluble antigen in test wells.

†% of reduction $= \dfrac{\text{(net \% lysis obtained with immune lymphocytes alone)} - \text{(net \% lysis obtained with immune lymphocytes plus soluble antigen)}}{\text{net \% lysis obtained with immune lymphocytes alone}}$

‡H–2^b was solubilised with papain and purified 200-fold from B6 spleen cells (M.J.R., unpublished data). When labelled, 40% of the preparation can be specifically precipitated with anti-H–2^b alloantisera.

We have demonstrated that efficient killing of allogeneic targets by T lymphocytes is generated by syngeneic immunisation (Table 1); that efferent inhibition of cytotoxicity by alloantisera can be non-specific (Fig. 1); that specific afferent inhibition of the cytotoxic response is only provided by syngeneic anti-tumour serum, not alloantisera (Table 2); that complete inhibition of cytotoxic reactions can only be obtained with soluble tumour antigen, not H–2 antigen (Table 3) and that cytotoxicity against syngeneic targets can be generated by allogeneic immunisation[14,17].

These data strongly suggest that there is no H–2 restriction of T-cell-mediated cytotoxicity to specific leukaemia-associated antigen(s) in this system. The findings are also contrary to the hypothesis of the TAA measured by our cytotoxicity assay being an (H–2) adaptor-(tumour) antigen complex. The discrepancy between these results and other reports of H–2 restriction could be due to differences in the assays. We have found that a 4–10 h ^{51}Cr release assay which was used by others[1–7], fails to detect the killing of allogeneic targets which may require longer incubation (20–40 h) (ref. 14). The explanation for this discrepancy is that *MHC* genes can play some role in the initial recognition phase of the cytotoxic reaction, thus enhancing short term killing in syngeneic target effector combination. The *MHC* genes are not essential, however, because recognition of specific, non-MHC antigens by allogeneic effector cells can produce effective cytotoxicity which becomes evident with longer incubation time.

We thank Mr B. Smith for technical assistance and Ms Linda Brunson for help with the preparation of the manuscript.

Active site of bovine factor XI (plasma thromboplastin antecedent)

FACTOR XI (plasma thromboplastin antecedent) is a plasma glycoprotein which participates in the early stages of blood coagulation[1]. A deficiency of this protein leads to a haemorrhagic disease in which the intrinsic pathway of blood coagulation is partially or completely blocked[2]. During normal coagulation, factor XI is converted to a serine protease (factor XI$_a$)[3], and this enzyme in turn activates factor IX (Christmas factor) by limited proteolysis[4]. Factor XI$_a$ is inhibited by serine protease inhibitors such as diisopropyl phosphorofluoridate, and this inhibitor is bound to a serine residue in the active site of the enzyme[3]. We recently purified bovine factor XI approximately 28,000-fold in 30% yield. The final preparation was

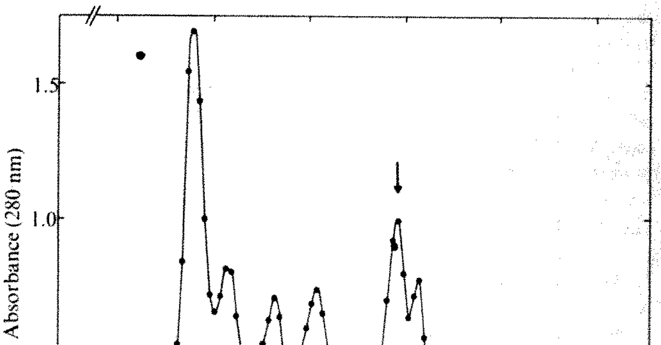

Fig. 1 Gel filtration pattern of the cyanogen bromide digest of *S*-pyridylethyl bovine factor XI. Factor XI, 40 mg, was pyridylethylated by the method of Friedman *et al.*[15] and the protein was separated from the salt and excess reagent by gel filtration on Sephadex G-50 (1.8 cm × 50 cm column) in the presence of 9% formic acid. Cyanogen bromide digestion was carried out by dissolving 40 mg of the salt-free *S*-pyridylethyl factor XI and 80 mg of cyanogen bromide in 2 ml of 70% formic acid, and the reaction was allowed to proceed for 24 h at 4 °C. After lyophilisation, the digest was fractionated by gel filtration on Sephadex G-75 (1.6 cm × 90 cm column) in the presence of 9% formic acid. The flow rate was 4.2 ml h^{-1} and fractions were collected in 1.4 ml per tube. The solid bar shows the fractions of peak 6 that were combined and lyophilised.

Fig. 2 Active site sequence of bovine factor XI and several other blood coagulation proteins. Amino-terminal sequence analysis was performed on 1.2-mg samples of peak 6, Fig. 1, with a Beckman sequencer Model 890A. The operation of this instrument and the methods used are adaptations[16] of Edman and Begg's technique[17]. Phenylthiohydantoin amino acids were identified by gas chromatography after silylation or directly by high-pressure liquid chromatography[18]. Amino acid residues in factor XI that are identical with other plasma serine proteases are shown in blocks. —, spaces inserted to bring the five proteins into alignment for better homology. The numbering system is that of chymotrypsin where the active site serine is residue 195. * Ref. 19; † ref. 20; ‡ ref. 21; § ref. 22.

homogeneous as measured by sodium dodecyl sulphate polyacrylamide gel electrophoresis and immunoelectrophoresis[5]. It has a molecular weight of 124,000 as determined by sedimentation equilibrium and is composed of two similar or identical polypeptide chains held together by a disulphide bond(s). We present here data showing that bovine factor XI contains an amino acid sequence which is very similar to the active site region of many other serine proteases involved in the coagulation process.

S-pyridylethyl factor XI was digested with cyanogen bromide and the polypeptide fragments were fractionated by gel filtration on Sephadex G-75 (Fig. 1). Twelve ultraviolet-absorbing peaks were obtained. Peak 6 (shown by the arrow) migrated as a single band on sodium dodecyl sulphate polyacrylamide gel electrophoresis and had a molecular weight of approximately 5,500. The amino-terminal sequence of this polypeptide chain is shown in Fig. 2, with the active site regions of several other coagulation proteins from bovine plasma. Twenty residues were identified in this peptide. The amino-terminal residue was valine and no other amino acids were detected. The active site serine, corresponding to serine 195 in chymotrypsin, appeared in position 17 of the peptide. The yield of this residue, however, was poor. For the remaining amino acids, the repetitive yields for the degradations were about 95% and over 80% of the expected quantities of the phenylthiohydantoins based on the weight of the lyophilised peptide. It is clear from these data that bovine factor XI contains an amino acid sequence which is characteristic of the active site regions of a number of plasma serine proteases. This sequence is also homologous to that found in pancreatic trypsin[6] and is consistent with the fact that factor XI_a has esterase activity towards benzoylarginyl ethyl ester[3] and participates in blood coagulation by splitting an arginyl valyl peptide bond in factor IX (P. Lindquist, K. Fujikawa and E. W. Davie, in preparation). A specificity toward basic amino acids is also consistent with the fact that residue 189 in factor XI is aspartic acid. This residue is in the bottom of the binding pocket in trypsin and forms an ion pair with an arginine or lysine residue in the substrate[7–12].

Bovine factor XI, like factor XII (Hageman factor), factor IX_a, factor X_a (activated Stuart factor) and thrombin, also contains an aspartic acid residue in position 194 next to serine 195. When trypsinogen and chymotrypsinogen are converted to enzymes, aspartic acid 194 forms an ion pair with the newly formed α-amino group of isoleucine which is generated during the activation reaction[13,14]. It seems likely that a similar mechanism may occur when factor XI is converted to a serine protease by limited proteolysis.

Factor XI contains 12 methionine residues per 124,000 g of glycoprotein[5]. This should yield 14 cyanogen bromide peptides for a molecule composed of two non-identical chains, or seven peptides for a molecule composed of two identical chains. Approximately 12 cyanogen bromide fractions were detected by gel filtration on Sephadex G-75 (Fig. 1). Examination of each of these peaks by sodium dodecyl sulphate polyacrylamide gel electrophoresis indicated, however, that many of these peaks were not homogeneous. Thus, the question as to whether factor XI is composed of two identical chains or two very similar chains remains to be answered.

Depression: a new animal model sensitive to antidepressant treatments

A MAJOR problem in the search for new antidepressant drugs is the lack of animal models which both resemble depressive illness and are selectively sensitive to clinically effective antidepressant treatments. We have been working on a new behavioural model in the rat which attempts to meet these two requirements. The method is based on the observation that a rat, when forced to swim in a situation from which there is no escape, will, after an initial period of vigorous activity, eventually cease to move altogether making only those movements necessary to keep its head above water. We think that this characteristic and readily identifiable behavioural immobility indicates a state of despair in which the rat has learned that escape

Table 1 Effects of various psychotropic drugs on the total duration of immobility induced in rats forced to swim in a narrow cylinder for 5 min

The rats had previously received three intraperitoneal injections 24, 5 and 1 h before testing. The doses, expressed in terms of the salt, are those given at each injection. The drugs were dissolved or suspended in 0.9% NaCl and injected in a constant volume of 5 ml kg^{-1}. Differences from control values were assessed for statistical significance using the Dunnett test (two-tailed)[15].

is impossible and resigns itself to the experimental conditions. This hypothesis receives support from results presented below which indicate that immobility is reduced by different treatments known to be therapeutic in depression including three drugs, iprindole, mianserin and viloxazine which although clinically active[1–3] show little or no 'antidepressant' activity in the usual animal tests[4–6].

Naive male Sprague–Dawley (Charles River) rats weighing between 160 and 180 g are plunged individually into a vertical plexiglass cylinder (height 40 cm; diameter 18 cm) containing 15 cm of water maintained at 25 °C. After 15 min in the cylinder they are removed and allowed to dry for 15 min in a heated enclosure (32 °C) before being returned to their individual cages. This treatment produces long periods of immobility in the water (10–12 min total duration) and the rats on removal are mildly hypothermic (−3 °C) and are hypoactive for periods up to 30 min. 24 h later the rats are replaced in the cylinder and the total duration of immobility is measured during a 5-min test. Rats submitted to this procedure will remain immobile for 75% of the duration of the test (see Table 1) thus providing a suitable baseline for measuring the effects of drugs which decrease or even increase immobility.

Drugs and doses investigated are shown in Table 1. To optimise the pharmacological effect[7] and at the same time to imitate more closely clinical usage, we administered the drugs in a series of three intraperitoneal injections 24, 5 and 1 h before testing on day 2, the first injection being given immediately before replacing the animals in their cages on day 1. Electroconvulsive shock (ECS; 30 mA, 50 Hz, 1 s) was delivered through ear-clip electrodes according to the same time schedule as for drug injections.

Table 1 shows that all the antidepressants tested as well as ECS significantly reduced immobility. With the tricyclic compounds, particularly amitriptyline, this 'antidepressive' effect was accompanied by lowered muscle tonus and diminished motor activity outside the test situation suggesting sedation. Biphasic effects were observed with mianserin and iprindole: a reduction in immobility at lower doses followed at higher doses by a return to control levels and a marked loss of muscle tonus. Viloxazine decreased immobility without apparent sedative effects. The monoamine oxidase inhibitor, nialamide, reduced immobility but induced small repetitive body movements which were not observed with the tricyclic antidepressants; loss of muscle tonus was noted at 100 mg kg^{-1}. The two psychostimulants (+)-amphetamine and caffeine also reduced immobility but in contrast to the tricyclic compounds induced a marked hyperactivity; with (+)-amphetamine stereotyped head movements were observed at 1.5 and 3 mg kg^{-1}. Neither chlordiazepoxide nor diazepam affected the duration of immobility even at doses which produced noticeable ataxia. In contrast, both chlorpromazine and the reserpine-like compound RO4-1284 increased mobility; with RO4-1284 a ceiling effect was already observed at 1 mg kg^{-1}, a non-cataleptic dose.

We conclude from the results obtained that the immobility induced in these experiments reflects a state of lowered mood in the rat. Immobility was reduced by antidepressant drugs and ECS, was unaffected by anxiolytics, and was increased by drugs known to be capable of inducing depressive states in man[8,9]. The positive findings obtained with amphetamine and caffeine do not stand in contradiction to this conclusion as both compounds do possess some clinical antidepressant activity[10] and besides, the effects observed could be distinguished qualitatively from those of the non-stimulant antidepressants.

The results obtained with mianserin deserve comment because this compound, although clinically active[2], possesses a profile of pharmacological and biochemical activity which is almost the mirror image of that expected of a classical tricyclic antidepressant: it potentiates the effects of reserpine and antagonises the effects of amphetamine[11]. It does not inhibit the re-uptake of monoamines[12] and is moreover a potent blocker of central 5-hydroxytryptamine receptors[13]. Although providing no explanation for the mechanisms of action of mianserin, it is noteworthy that the present procedure, which is based on behavioural rather than biochemical concepts, is the first animal test model which would predict an antidepressant action for this compound. Furthermore the bimodal effect observed strikingly parallels clinical observations showing an optimal antidepressant effect at intermediate doses[14].

These positive findings, together with those obtained with the two other atypical compounds, iprindole and viloxazine, raise the intriguing possibility that the method described here might be capable of discovering new types of antidepressant agents hitherto undetectable using classical screening tests.

Benzodiazepine receptors in rat brain

HIGH affinity binding of tritium labelled morphine and morphine-like drugs to membranes in brain homogenates[1–3] was a decisive advance in the characterisation of opiate receptors and the discovery of enkephalines and endorphines. We report here experiments which suggest that another important group of psychoactive drugs, the benzodiazepines, bind to specific receptors on the membranes of rat brain cells. This suggests that there may be an unknown endogenous neurotransmitter which is the natural ligand for the benzodiazepine receptor. The binding sites are distributed unevenly through the brain, and displacement potencies of benzodiazepines correlate with pharmacological effects predictive of anxiolytic activity.

Whole forebrains (excluding cerebellum and pons-medulla) of 150 g Wistar rats were homogenised gently in 20 volumes of ice-cold 0.32 M sucrose, centrifuged at 1,000*g* for 10 min and recentrifuged at 30,000*g* to give a crude P_2-synaptosomal fraction. The P_2-fraction was rehomogenised in an equal volume of hypotonic, 50 mM, Tris-HCl (*p*H 7.5). The binding assay consisted of 500 µl test drug solution and with ^{3}H-diazepam as the radioactive ligand, usually at 1.6 nM (^{3}H-diazepam (*N*-methyl-^{3}H) 14, 4 Ci mmol^{-1}; provided by Dr Willy Haefely, Hoffmann-La Roche). The mixture was preincubated for 5 min at 37 °C before addition of ^{3}H-diazepam followed by a 15 min additional incubation. The samples were cooled for 30 min in an ice bath and membranes with bound ^{3}H-diazepam were isolated on Whatman GF/C glassfibre filters. At the end of the incubation 10 ml of iced buffer (50 mM Tris-HCl, *p*H 7.4 was added, immediately before filtering, and the filter was washed with an additional 10 ml iced buffer and bound diazepam was estimated by conventional scintillation counting.

The amount of nonspecific binding, defined as binding in the presence of excess unlabelled ligand, was very low. Addition of diazepam at 3 μM to the binding assays displaced 91–93% of the total ^{3}H-diazepam binding. Specific ^{3}H-diazepam binding was saturable (Fig. 1) and maximal binding was obtained with about 50 nM ^{3}H-diazepam. A Scatchard analysis of the results in Fig. 1 yielded a single straight line in the concentration range below 50 nM, indicating the presence of a single binding site. The affinity constant, K_D (concentration of ^{3}H-diazepam giving half-maximal binding) was 2.6 nM and the total number of binding sites was 18 pmol per g original tissue. Hill plots (not shown) had a slope of 1.0–1.1 indicating absence of cooperativity.

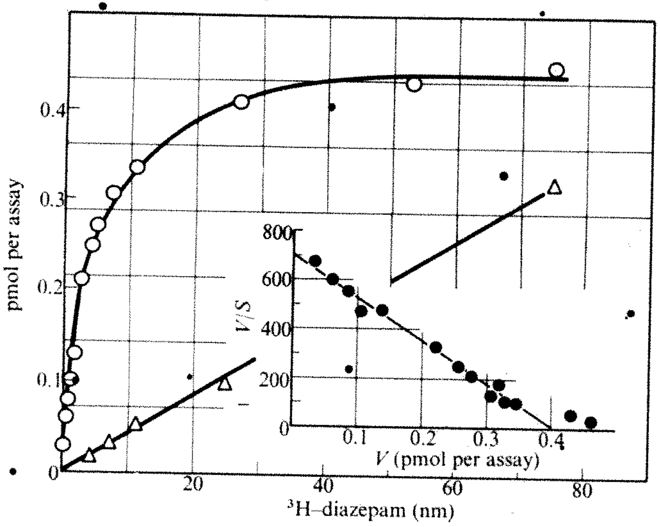

Fig. 1 Binding of ^{3}H-diazepam to membranes from 25 mg rat forebrain. ^{3}H-diazepam, 0.24–75 nM was incubated in triplicate with or without excess cold diazepam. Specific binding (○) is the total binding minus the binding which is not displaced by excess (3 μM) diazepam (●). Insert shows the same data transformed to Scatchard plots (V, specific binding in pmol per 25 mg tissue; S, ^{3}H-diazepam concentration in pM). The Scatchard plot indicates one binding site with affinity constant, $K_D = 2.6$ nM (reciprocal of the slope value) and maximal binding of 18 pmol per g original tissue (intercept on abscissae). The experiment was repeated, giving closely similar results. Counting efficiency was 44%.

Measurement of specific ^{3}H-diazepam binding (at 1.6 nM) in 10 rat brain regions showed an uneven regional distribution. The greatest binding was found in the frontal and occipital cortex where the binding was three to fourfold higher than the lowest binding in the pons-medulla. The hippocampus, which may be an important site of action for benzodiazepines in the limbic system[4], had intermediate binding levels.

The ^{3}H-diazepam binding site was highly selective for benzodiazepines. Twenty one benzodiazepines (Table 1) displaced ^{3}H-diazepam with IC_{50} values in the range of 3×10^{-9} to 10^{-4} M while some other 'minor tranquillisers', such as meprobamate, barbiturates and ethanol, were inactive at 0.1 mM. Several presumed neurotransmitters were tested as ^{3}H-diazepam displacers. None of these (acetylcholine, noradrenaline, dopamine, serotonin, GABA, L-glutamate or glycine, all at 0.1 mM) or their antagonists (phenoxybenzamine, propranolol, pimozide, clozapine, methysergide, bicuculline, picrotoxin or strychnine, all at 3×10^{-6} M) exhibited any displacement activity. Various other compounds, including etorphine, nalorphine and muscimol (all at 3×10^{-6} M) were also inactive.

Even though the binding of a compound may be saturable and show remarkable selective displacement properties it may not occur at meaningful recognition sites[5]. The diazepam receptor which we describe here, however, seems to be physiologically significant since it can be correlated to pharmacological activities. Efficacies in several pharmacological tests are available for most of the benzodiazepines used in the present study[6]. Excellent correlations ($P > 0.001$) were observed between ^{3}H-diazepam displacement potency on the one hand and cat muscle relaxant effect, impairment of mouse rotarod performance, inhibition of electric shock induced fighting in mice and antagonism of pentazol induced convulsions in mice, on the other. Weak correlation was found to taming of cynomolgus monkeys ($P = 0.01$, $r = 0.655$). Displacement of ^{3}H-diazepam binding correlates best with the cat muscle relaxant effect (Fig. 2). While the pharmacologial tests listed above are predictive of anxiolytic and anticonvulsant activity we found no correlation with the non-predictive conditioned avoidance tests (either shock increase or escape failures) in the rat.

Table 1 Inhibition of specific ^{3}H-diazepam binding (1.6 nM) to rat brain membranes by benzodiazepines

Compound*	IC_{50}(nM)†
RO 5–4023 (clonazepam)	5
RO 5–4200 (flunitrazepam)	5
Lorazepam	7
RO 5–3027	9.2
RO 5–3590	13.1
RO 5–6901 (flurazepam)	28
RO 5–2807 (diazepam)	34
RO 5–3059 (nitrazepam)	34
RO 5–3350 (bromazepam)	48
RO 6–6616 (chlorazepate)	62
RO 5–2904	76
Oxazepam	80
RO 5–2181	135
RO 5–4528	389
Chlordiazepoxide	1,072
RO 5–5807	4,487
RO 5–3785	5,686
RO 5–4556 (medazepam)	6,217
RO 5–3636	8,270
RO 5–4933	<30,000
RO 5–4864	163,522

Serial dilutions of benzodiazepines (in duplicate experiments) were added to the high affinity binding assay (see text).

*Chemical structures given in ref. 6.

†IC_{50}, concentration causing 50% inhibition of specific ^{3}H-diazepam binding.

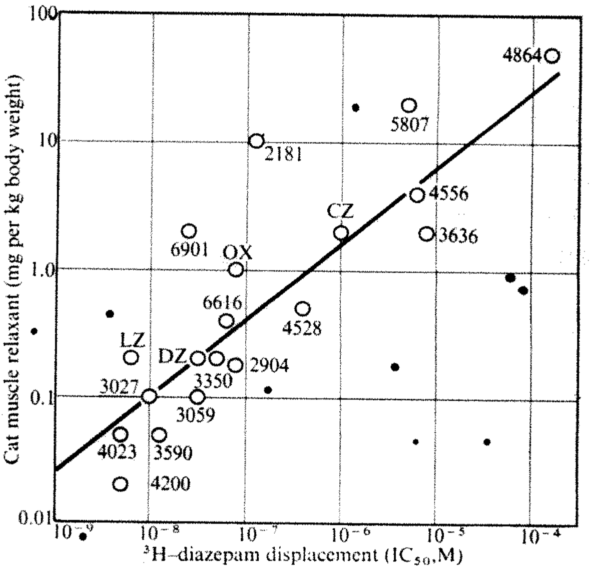

Fig. 2 Correlation between IC_{50} values for ^{3}H-diazepam displacement by 19 benzodiazepines (from Table 1) and cat muscle relaxant (oral dosage) effect. The best curve fit was assessed by linear regression analysis ($r = 0.891$; $P < 0.001$). Numbers on graph indicate RO code number, OX, oxazepam; DZ, diazepam; LZ, lorazepam; CZ, chlordiazepoxide.

In a comprehensive review, Randall *et al.*[6] concluded that the 'actions of benzodiazepines cannot be related in a direct manner to the action of neurotransmitters in the brain'. The proposal[7] that benzodiazepines act on glycine receptors seems now unlikely in view of electrophysiological data[8,9] and our finding that neither glycine nor its antagonist strychnine displace ^{3}H-diazepam binding. Further, the benzodiazepines were about 10,000 times more potent as displacers of ^{3}H-diazepam binding than ^{3}H-strychnine binding. And ^{3}H-diazepam does not apparently bind to GABA-receptors, since GABA itself, its potent agonist muscimol and its antagonists picrotoxin and bicuculline were completely inactive as ^{3}H-diazepam displacers. The failure of benzodiazepines to block ^{3}H-GABA binding to brain membranes[10] further indicates the lack of direct benzodiazepine interactions with GABA receptors. These results, however, are not inconsistent with the proposal that benzodiazepines exert their physiological effects through GABA[11], since such effects may be indirect (for example, benzodiazepines might facilitate GABA release).

Our findings strongly suggest that the brain possesses specific receptors for benzodiazepines which may mediate their pharmacological actions. The exact mechanisms by which benzodiazepines exert their characteristic pharmacological and clinical effects remain unknown. A search for a hitherto undiscovered endogenous transmitter substance, acting on the benzodiazepine receptor therefore seems worthwhile.

Axotomy causes loss of muscarinic receptors and loss of synaptic contacts in the hypoglossal nucleus

MUSCARINIC receptors in the brain and ileum can be studied by means of the binding of radiolabelled cholinergic antagonists[1,2]. The basic criteria for receptor-specific labelling are that there should be a saturable component of binding and that the binding of the radiolabelled ligand should be inhibited by pharmacologically effective concentrations of drugs which are known to act at muscarinic receptors and not by drugs that act at different receptors. In addition, the saturable binding component should be restricted to tissues known from pharmacological experiments to contain muscarinic receptors. These criteria are satisfied by tritiated propylbenzilylcholine mustard (^{3}H-PrBCM)[3], a potent irreversible muscarinic antagonist the binding of which to rat brain sections can be demonstrated autoradiographically. The evidence which suggests that the bulk of tissue radioactivity is associated with muscarinic receptors is that in autoradiographs the regional variation of autoradiographic grain density parallels the intensity of specific ^{3}H-PrBCM binding observed by *in vitro* assay on brain homogenates from selected regions, and that in the homogenates 65–85% of the bound radioactivity is blocked by pretreatment with the classical muscarinic antagonist, atropine (10^{-6} M). In the forebrain the general features of the distribution of ^{3}H-PrBCM binding to thin sections correspond closely with the findings of Kuhar and Yamamura[4,5] who used the non-covalently bound antagonist ^{3}H-3-quinuclidinylbenzilate. We report here, however, that in the brain stem the hypoglossal nuclei are heavily labelled with ^{3}H-PrBCM. In light microscopic autoradiographs (Fig. 1*a*, left side) the grains are distributed throughout the neuropil of the hypoglossal nucleus. The cytoplasm and nuclei of the large hypoglossal neuronal somata (Fig. 1*b*) are unlabelled. The density of the silver grains falls abruptly at the borders of the hypoglossal neuropil. This clear demarcation of the labelled hypoglossal neuropil is abolished by atropine pretreatment (Fig. 1*c*).

The present results are based on a total of 48 adult female Wistar rats in which the hypoglossal nerve was cut on one side in the neck. In 30 animals the brains were prepared for light microscopic autoradiographic study of receptor binding, and in a further 18 animals the brains were prepared for an electron microscopic study of synapse numbers.

Several studies[6-9] of the effects of axotomy on the hypoglossal nucleus have shown that by 1 week after operation there is a loss of about 50% of the synapses on the hypoglossal motoneurones. If the hypoglossal axons are able to regenerate and re-establish neuromuscular contacts, synapses reappear in the hypoglossal nucleus, indicating that the synaptic 'disjunction' is reversible. We have examined the hypoglossal nucleus at various times after section of the hypoglossal nerve on one side, and the preliminary series of experiments indicated that two changes are detectable within 2 d after axotomy, and seem to have reached completion by 7–10 d after operation.

There was a marked decrease in the intensity of binding of ^{3}H-PrBCM. Since the nerve arises almost exclusively from the hypoglossal nucleus of the same side, and the two nuclei lie immediately adjacent to each other on either side of the midline, the opposite nucleus can be used as a control in the same coronal section. A representative indication of the magnitude of the changes may be seen from the grain counts taken from the sections shown in Fig. 1*a* and *c*. The numbers of silver grains per $10^{4}\ \mu m^{2}$ of section were 305±5 over the unoperated hypoglossal nucleus, 209±4 over the hypoglossal nucleus of the operated side (6 d after axotomy), and 123±3 over the hypoglossal nucleus of the unoperated side in the adjacent section (Fig. 1*c*) pretreated with atropine. Subtracting the atropine counts, this indicates that section of the hypoglossal nerve had caused a fall in the intensity of labelling of the hypoglossal nucleus of the operated side to 47% of its intensity on the unoperated side.

At the electron microscopic level, we counted the total numbers of synapses per unit area of section. As in the studies of Sumner[7] we found that there was an almost 50% reduction in the total numbers of synapses by 1 week after operation.

If the hypoglossal nerve is able to regenerate and re-establish contact with an appropriate peripheral target tissue, these changes are reversed. The hypoglossal motoneurones re-acquire a normal complement of afferent synapses[6-9] and our observations on the rats with the longer survival times showed that in those cases where the hypoglossal nerve had grown back, binding of ^{3}H-PrBCM in the hypoglossal neuropil had also recovered to normal levels. In some animals, the regenerating

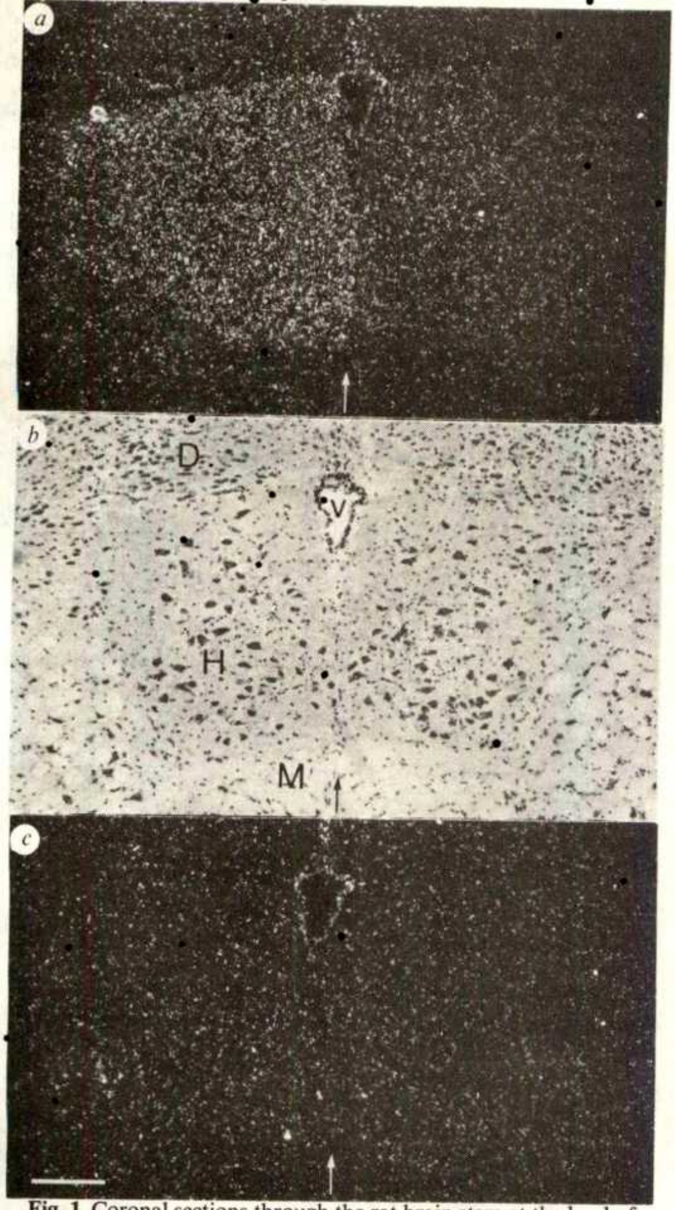

Fig. 1 Coronal sections through the rat brain stem at the level of the caudal medulla, where the hypoglossal nucleus has its major cross sectional area. The arrows show the midline. *a*, Dark field photomicrograph showing the intense deposition of autoradiographic silver grains over the hypoglossal nucleus on the left side of the picture (side of the intact hypoglossal nerve). Labelling falls abruptly at all the boundaries of the hypoglossal neuropil. On the opposite side, where the hypoglossal nerve had been sectioned 6 d previously (right side of the picture), the labelling is 47% of its intensity on the unoperated side. *b*, Bright field photomicrograph of the same section to show the cytoarchitectonic areas. H, hypoglossal nucleus, D, dorsal vagal nucleus, M, medial lemniscus, v, caudal ('closed') part of the fourth ventricle. *c*, Dark field photomicrograph of the adjacent section, which had been pretreated with 10^{-6} M atropine to abolish specific muscarinic antagonist binding. The hypoglossal nucleus shows no labelling above the level of the surrounding areas. Scale bar, 200 μm. For autoradiographic study of muscarinic receptor binding, the animals were anaesthetised with ether and perfused briefly with ice-cold Krebs–Henseleit medium. The brains were dissected out, frozen in solid carbon dioxide, and mounted on cryostat chucks. Coronal sections (12 μm thick) were cut at −15 °C, thaw-mounted on to gelatinised slides and pre-fixed in 0.1% glutaraldehyde in Krebs–Henseleit medium at 5 °C for 15 min. Pre-incubation was carried out for 15 min at 30 °C in Krebs–Henseleit medium with or without 10^{-6} M atropine, followed by addition of cyclised ^{3}H-PrBCM (40 Ci mmol^{-1}) to a final concentration of 2.4 nM for a further 15 min; these conditions lead to a more than 98% saturation of the receptors. The incubation was terminated by a quick wash in distilled water and post-fixation in Carnoy's fluid followed by several extensive washes in absolute alcohol. Slides were dipped in a 1:1 dilution of Ilford G5 nuclear emulsion, exposed at 6 °C for 14 d, developed in Ilford Phen-X, and counter-stained with cresyl fast violet.

proximal nerve stump had reconnected only incompletely, or not at all to the distal trunk. In these cases, the binding of ^{3}H-PrBCM had returned only in patches. Sumner[10] has shown that if the cut hypoglossal nerve is not allowed to re-establish peripheral contacts, there is no recovery of synapse numbers. Taken together, these observations indicate that in the case of the hypoglossal motoneurones axotomy causes both loss of synaptic contacts and loss of binding of ^{3}H-PrBCM, and both these changes are reversed if the axons regenerate appropriate terminal contacts, but not if they fail to do so.

In several sites in muscle[11,12] and nerve[13], experimental destruction of the presynaptic element causes postsynaptic cholinergic (nicotinic) receptors to increase in number, and a new population of receptors to appear outside their normally restricted subsynaptic location, indicating that the maintenance of normal receptor number and distribution depends on the presence of the presynaptic element. Although we know of no direct electrophysiological evidence for the occurrence of cholinergic transmission using postsynaptic muscarinic receptors in the hypoglossal nucleus, the occurrence of specific muscarinic antagonist binding strongly suggests the presence of such a mechanism. In the present experiments, damage to the postsynaptic neurone caused a decrease in the amount of binding of muscarinic antagonist, and a loss of synaptic contacts, and our preliminary results from a closely timed series of experiments suggest that the binding loss may preceed the loss of synapses. Our method of applying the PrBCM directly to the cut sections makes it likely that the decreased binding is due to a loss of receptors, and not to changes in the accessibility of the receptor (for example by the interposition of a glial barrier).

Taken together with the observation that axotomy causes a decrease in sensitivity to transmitter in several types of neurones (for example see refs 14 and 15), the findings in the hypoglossal nucleus suggest that there could be a converse regulatory relationship—namely that the presence of receptors may be necessary for the maintenance of the physical contact between the pre- and the postsynaptic elements.

Specific long-lasting potentiation of synaptic transmission in hippocampal slices

SHORT bursts of tetanic stimulation (10–50 Hz for 10–15 s) give rise to long-lasting potentiation (LLP) of synaptic transmission in the intact hippocampal formation[1] and in hippocampal slices[2]. The potentiation may last several hours. Because of the time course and the small number of conditioning impulses required, the process may have general interest as a model for long-term plasticity in the nervous system. Studies of the mechanisms underlying LLP have been hampered, however, by lack of control with the size of the input volley and of data on membrane potential changes of the participating cells. Further, it is not known whether the potentiation is specific for the tetanised input. Schwartzkroin and Wester[2] found an unchanged antidromic field potential, and concluded that there were no general postsynaptic changes. Lynch *et al.*[3], however, found a reduction in glutamate sensitivity during the potentiated stage, and suggested that a reduction in excitability had taken place. We report here experiments on transverse hippocampal slices[4] of guinea pigs in which we have monitored the size of two independent afferent inputs, one of which is tetanised to produce LLP, leaving the other as a control line to check for non-specific changes in excitability. Furthermore, intracellular recordings support our suggestion that LLP is caused by a specific augmentation of transmitter release.

Figure 1 shows the location of a typical CA1 neurone with reference to the layers of the hippocampal slice, and the arrangement of the stimulating and recording electrodes used to study two independent pathways, one in the layer of basal dendrites (str. oriens) and the other in the layer of apical dendrites (str. radiatum). Both excite the CA1 pyramidal cells through fibres running parallel to the pyramidal layer. The fibres have *en passage* boutons which synaptically excite dendrites at the same level as the corresponding stimulating cathode (Fig. 1*b*). Field potentials were recorded with three electrodes, two placed at the same level as the two stimulating cathodes, and the third in the pyramidal layer, all three being placed on a line normal to the pyramidal layer, and recording from the same population of pyramidal neurones. In some experiments, the pyramidal electrode was used for intracellular recording.

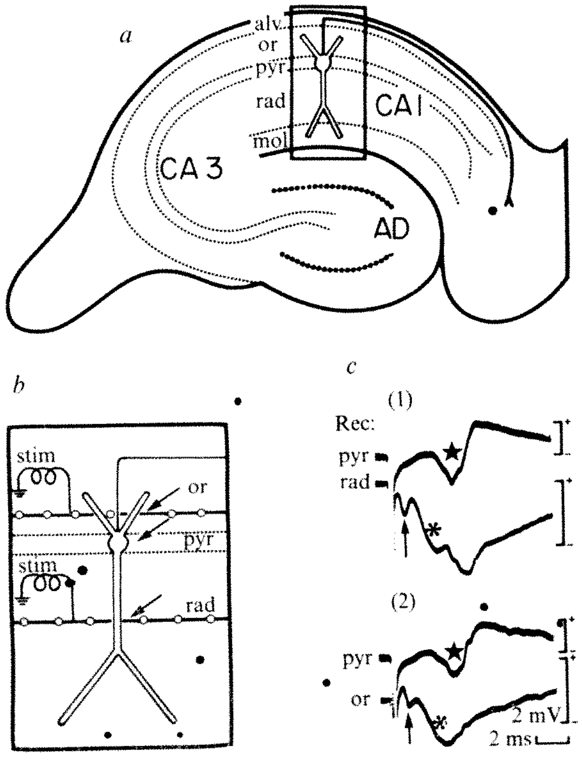

Fig. 1 *a*, Schematic drawing of the hippocampal slice. alv, alveus; or, str. oriens; pyr, str. pyramidale; rad, str. radiatum; mol, str. moleculare. *b*, Enlargement of box in *a* to show the arrangement of stimulating cathodes (stim) and recording electrodes (→) along two independent pathways, one in str. oriens and one in str. radiatum; *c*, Example of recorded potentials showing presynaptic volley (↑), extracellular EPSP (*), and population spike (★) in response to stimulation of a radiatum (1) and an oriens pathway (2). Left-hand labels indicate recording sites.

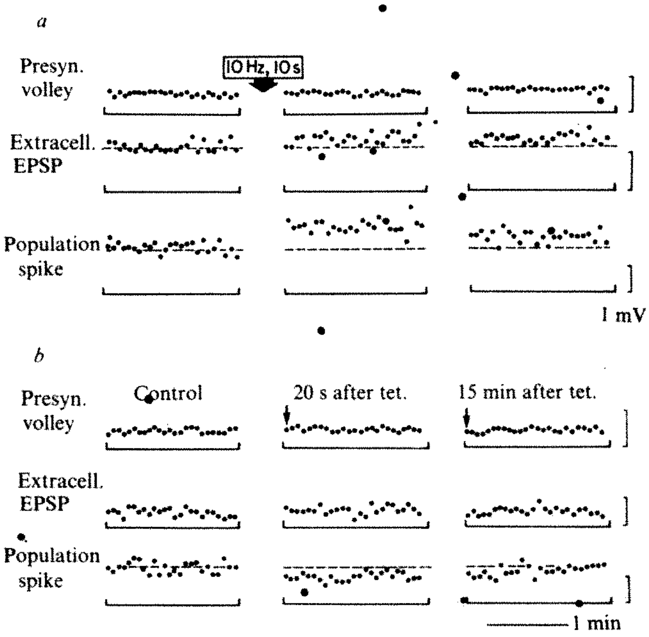

Fig. 2 Left-hand columns in *a* and *b* give control responses before a tetanus of 10 Hz for 10 s was delivered to the radiatum pathway. The middle column shows the responses obtained between 20 and 120 s and the right-hand column shows responses recorded between 15 and 16.7 min after the cessation of the tetanus. *a*, Increased amplitude of the extracellular EPSP in str. radiatum and of the population spike in the pyramidal layer in response to a constant radiatum fibre volley (0.25 Hz, 29 μA). A small increase of the presynaptic volley is seen in the right-hand plot. *b*, Lack of consistent changes of the amplitude of the presynaptic volley, extracellular EPSP recorded from str. oriens and of the population spike recorded from the pyramidal layer in response to stimulation of oriens fibres (0.25 Hz, 15 μA).

When a group of fibres was stimulated, the dendritic electrode at the same level recorded an initial diphasic deflection followed by a negative wave with an irregularly shaped peak (Fig. 1*c*). The initial diphasic deflection (↑) is taken as the sign of the presynaptic fibre volley for the following reasons: it was located strictly to the activated level, was linearly related to the EPSP amplitude, showed a conduction velocity of about 0.3 m s^{-1}, followed high-frequency stimulation, and was not changed by removal of Ca^{2+} from the bathing fluid (Andersen, Silfvenius, Sundberg and Wigström, unpublished observations). The following negative extracellular field potential (*) was directly correlated to intracellularly recorded EPSPs and is taken as the extracellular sign of EPSPs from a group of neighbouring cells. Finally, a population spike (★), which represents an envelope of unit discharges[5], was recorded from the pyramidal layer. The two pathways were stimulated alternately so that each line was tested every fourth second. We measured continuously the size of the presynaptic volley and the corresponding extracellular EPSP. Both may serve a measure of the input strength[6]. Further, we measured the size and peak latency of the population spike. After a control period of 15–30 min, a brief tetanisation was given to one of the pathways (10 Hz for 10 s or 50 Hz for 5 s).

Figure 2 shows synaptic transmission in the radiatum pathway to be greatly facilitated after tetanic stimulation of the same pathway, as indicated by an increased extracellular EPSP and a greatly enhanced population spike with reduced latency. Further, the probability of single unit discharges increased during the period of the enhanced extracellular EPSP. These effects subsided only gradually and could last > 1 h. It proved necessary to monitor the size of the presynaptic volley. In eight of 16 trials a transient increase of this deflection (< 10 min) occurred post-tetanically. Further, in some experiments, distinct and seemingly spontaneous changes of the presynaptic volley developed. Therefore, to assess the potentiation effects, input–output graphs were produced before and at various times after the tetanisation. Comparing the input–output curves taken before and after the tetanisation, a given afferent volley along the tetanised line gave rise to a larger extracellular EPSP (13 of 16 trials) and a larger (13/13) and shorter latency (12/13) population spike (Fig. 3). In none of the seven trials in which control line responses were measured, were there any observable changes in the latter, except a transitory and small change of the population spike, usually lasting < 3 min. The LLP, therefore, seems to be an input-specific effect.

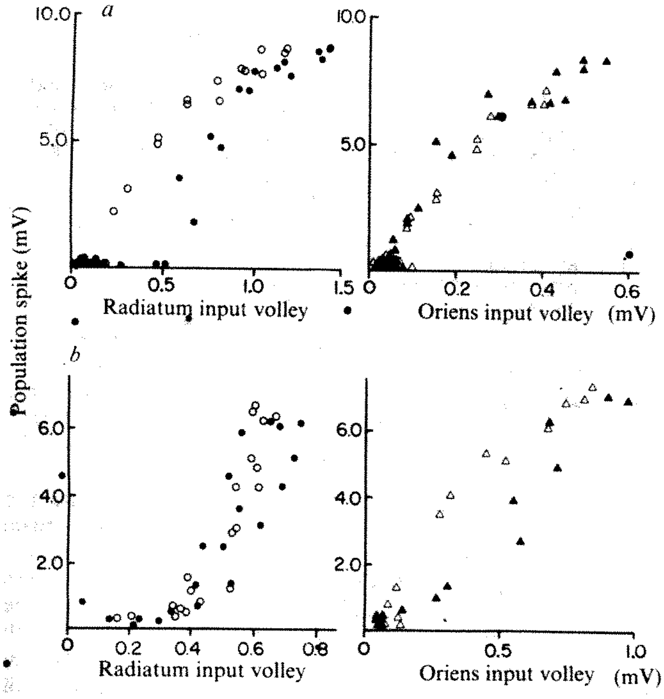

Fig. 3 Input–output graphs for radiatum line (left) and oriens line (right) in two slices. *a*, Slice in which tetanisation (50 Hz, 5 s) was given to str. radiatum. Responses to radiatum stimulation before (●) and after (○) tetanisation and to oriens stimulation before (▲) and after (△) tetanisation. *b*, Symbols as in (*a*) but a different slice and tetanisation (50 Hz, 5 s) now delivered to str. oriens.

We also compared the size of the presynaptic volley and the probability of discharge of single CA1 neurones. The input–output graphs changed after the tetanus in the same way as for the population spike. With intracellular recording the membrane potential, the size of the EPSP and the firing threshold of the spike were compared pre- and post-tetanically. In Fig. 4, three afferent volley sizes produce a larger EPSP after the tetanisation than before. The increased EPSP caused the spike to occur in response to a smaller input volley and with a shorter latency compared to the pre-tetanised values. The fact that the membrane potential did not change suggests that the increased EPSP is due to an augmented transmitter release. In these experiments we did not systematically test the spike threshold by injecting depolarising current pulses in the soma because this threshold was found to be the same as the threshold for synaptically activated spikes.

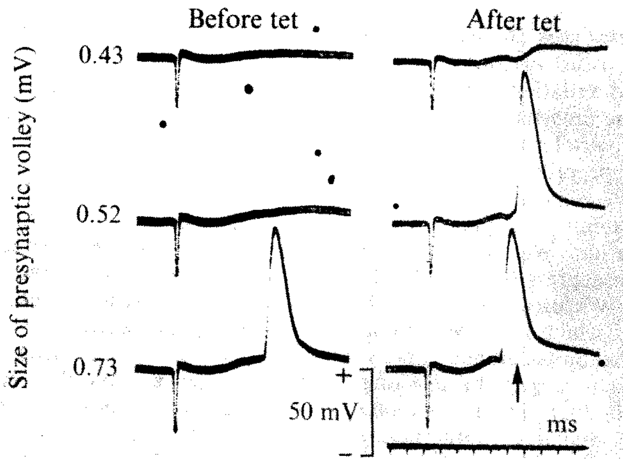

Fig. 4 Intracellular recording of responses to three differently sized radiatum fibre volleys. The peak-to-peak size of the volleys are given in mV on the left. Left-hand column were taken before, right-hand column 15 min after a 50 Hz, 5 s tetanus was delivered to the same radiatum fibres. After the tetanus a given input volley gives a larger and faster rising EPSP and increased probability of firing and a reduced latency. No significant change in the membrane potential occurred except during and shortly after the tetanus. Neither was there any change in the firing level of the action potential. The arrow indicates the latency of the control spike.

The claim for an input-specific process underlying the LLP rests on our observation of unchanged control line responses. Admittedly, small changes of these were seen, but an increase in excitability were as likely as a decrease, and both were unrelated to the tetanisation. Our failure to observe systematic changes in the control line responses makes it difficult to ascribe the reduced glutamate sensitivity seen during LLP to a general depression of post-synaptic excitability as done by Lynch *et al.*[3].

In conclusion, we believe the presented evidence suggests that short tetani of fibres having dendritic synapses on CA1 hippocampal pyramids lead to an input-specific and long-lasting potentiation (LLP) of synaptic transmission. The effect is hardly due to changes in the afferent volley since our method allows control of the latter. Because unwanted changes in the input volley can occur, we feel that experiments on LLP require adequate input control.

Heterosynaptic depression: a postsynaptic correlate of long-term potentiation

BRIEF trains of electrical stimulation delivered to any one of several hippocampal pathways often result in immediate and long-lasting enhancement of subsequent postsynaptic responses elicited by that pathway[1–5]. The unusual characteristics of these effects suggest that theories of long-term potentiation (specifically changes in transmitter release by the presynaptic terminal) which have evolved from work on invertebrate and neuromuscular preparations may not be appropriate to explain synaptic plasticity in hippocampus. We report here the results of experiments intended to examine the postsynaptic consequences of repetitive stimulation. We found that potentiation of one afferent tended to depress the target cell's responses to a second test input.

We used the *in vitro* hippocampal slice technique, details of which have been published[6,7]. Briefly, rats were stunned, the hippocampus rapidly dissected free, and then sliced at right angles to its longitudinal axis on a Sorvall tissue chopper. The slices (500 μm thick) were then transferred to a small recording chamber of our design[7] and immersed in a slightly modified glucose–Ringer solution. All experiments were run at 33 °C.

Figure 1 shows the experimental design. The CA1 field was chosen for the analysis because it receives two different inputs to completely different dendritic subfields—namely, the apical and basal dendritic fields. Because of this anatomical arrangement, it is relatively easy to study the interaction of two spatially separate afferents on the same postsynaptic neurones. One bipolar stimulating electrode (twisted 62-μm wire) was placed in the trajectory of the Schaffer collateral-'apical' commissural projections to the stratum radiatum of the CA1 pyramidal cells. A second bipolar electrode was localised in the stratum oriens of the CA1, a zone which contains a massive commissural projection to the basal dendrites of the CA1 cells[8,9]. A recording micropipette was then guided by visual landmarks and physiological responses (cell spikes) into the pyramidal cell body layer (stratum pyramidale). The distances between stimulating and recording electrodes were typically 1–3.0 mm. A total of 28 slices was tested.

Low voltage stimulation to these pathways produced the responses characteristic of the laminated hippocampal projections—a monophasic negative-going potential in the dendritic zone innervated by the stimulated afferent and a monophasic positive potential in the stratum pyramidale. The response was similarly positive but considerably attenuated in the dendritic zone across the cell body layer from the stimulated afferent. As voltage was increased the 'dendritic' negative potential grew larger and a prominent sharp negative deflection appeared in the positive response recorded from the cell bodies. This negative potential is likely to be generated by the synchronous spike discharge of several pyramidal cells, as shown by Anderson *et al.*[10], and, following their terminology, we refer to it as a 'population spike'.

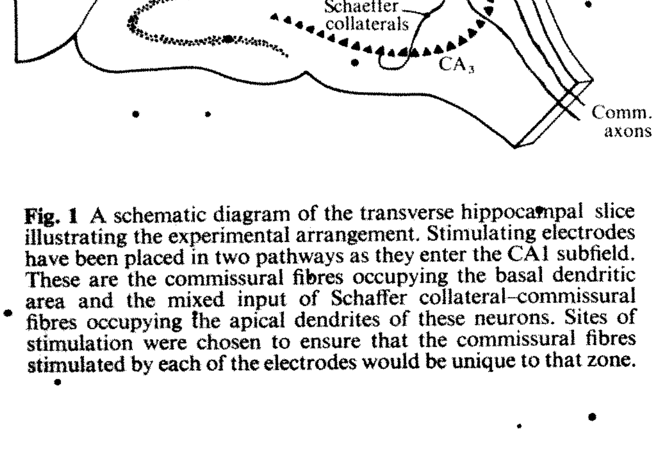

Fig. 1 A schematic diagram of the transverse hippocampal slice illustrating the experimental arrangement. Stimulating electrodes have been placed in two pathways as they enter the CA1 subfield. These are the commissural fibres occupying the basal dendritic area and the mixed input of Schaffer collateral–commissural fibres occupying the apical dendrites of these neurons. Sites of stimulation were chosen to ensure that the commissural fibres stimulated by each of the electrodes would be unique to that zone.

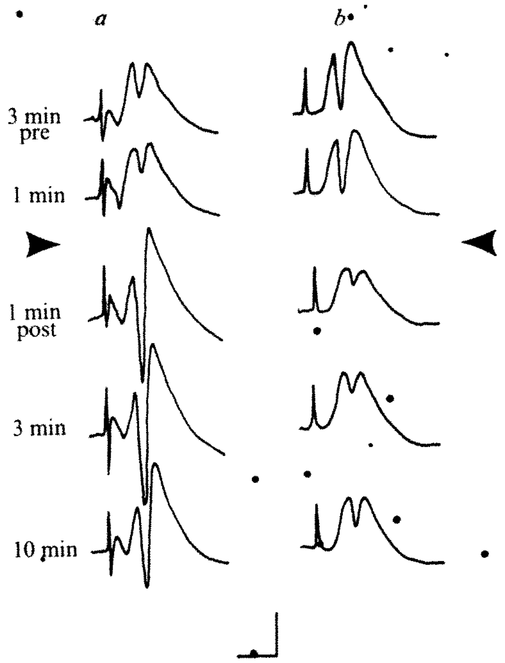

Fig. 2 An example of the depression seen in the commissural response (*b*) concommitant with post-tetanic potentiation of the Schaffer response (*a*). Note that all aspects of the commissural evoked response exhibit depression. The component most drastically reduced is the negative population spike, while the Schaffer population spike shows the greatest degree of potentiation following tetany. The potentiation stimulus consisted of a 15-Hz, 15-s train delivered (at test voltage) through the Schaffer electrode at the arrows. All records are an average of four responses; the test frequency was 0.2 Hz, pulse duration was 0.1 ms. Vertical scale, 1 mV; horizontal scale, 5 ms.

Following the placement of the three electrodes, the size of the responses evoked by the two electrodes was made approximately equal by adjustments of the stimulating voltages (usually 5–10 V). The voltages selected were adequate to generate a small (1 mV) population spike. The responses in both pathways were periodically tested with trains of four pulses presented at 0.2 Hz during a 5–10-min pretest. If these remained stable, a brief train (2–15 s) of 15-Hz stimulation was delivered to one of the two electrodes, then the frequency was returned to 0.2 Hz. In most experiments, the magnitude of the conditioning and test responses was sampled at 1-min intervals post-potentiation by averaging trains of four pulses given at 0.2 Hz. The potentiation train was delivered to the 'Schaffer' electrode in 13 slices and to the 'commissural' electrode in 15 cases.

During the stimulation train both the conditioning and test responses (that is, the responses to the electrodes which received the 15-Hz train and to the one which did not, respectively) were greatly augmented. After the termination of the train the two responses behaved quite differently. In 26 of 28 of the slices, the response elicited by the electrode which had delivered the high-frequency train was potentiated, particularly with regard to the population spike. This facilitation usually was evident within one or two pulses after the train and persisted for at least 15 min. Responses to stimulation in the non-potentiated pathway declined rapidly (over 15 s) towards baseline following repetitive stimulation of the other electrode, and in 22 of the cases entered a period of persistent depression (mean size of the population spikes tested at 2 min post-conditioning train was 68% of the control value ($P<0.001$) (Fig. 2 and see

Fig. 3). As was the case for potentiation, the depression was more evident in the population spike than in the slower field potentials.

Thirteen of the slices were tested for longer post-tetani periods and both potentiation and depression lasted for at least 15 min (Table 1). To test for effects longer than this it would be necessary to establish control procedures to insure that the status of the preparation remained stable for longer periods.

In these 13 slices we also delivered a tetanic train of stimulation to the depressed pathway, usually at 16 min after the first potentiation train. In all but one of these cases the depressed response showed marked potentiation, whereas in every case the previously potentiated responses were depressed (averages were 327% and 76% of the immediate pre-tetanus response 2 min following the reversal train).

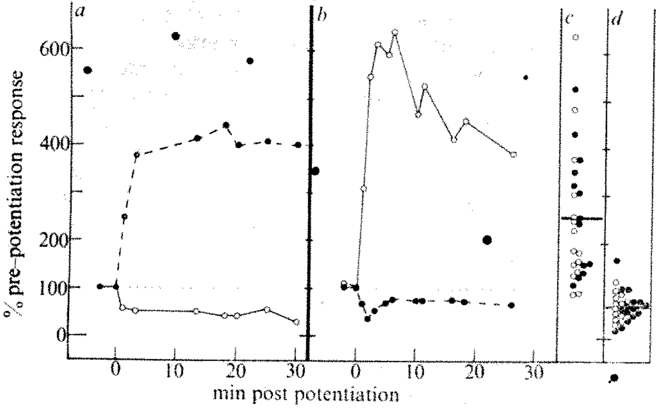

Fig. 3 Amplitude plot of the population spike evoked by both stimulating electrodes during 0.2-Hz 'test' stimulation. The figure shows the size of the population spikes both before and after a 15-Hz, 15-s train was delivered to either the Schaffer (*a*) or commissural (*b*) afferents at time 0 (different slices). *c* and *d* show potentiation and depression, respectively, of a group of slices whose responses were tested at 2 min after the potentiating train. Amplitudes are plotted as the percentage of the last non-potentiated response. Schaffer responses indicated by solid circles and commissural responses by open circles. Bars indicate means.

It seemed that, for most slices, long-term potentiation of one input to the pyramidal cells was accompanied by an unusually persistent depression of the response to remaining inputs. As the anatomical arrangements of the slice and the afferents used in this experiment are such as to make any axo-axonic interactions highly unlikely, our results suggest that brief trains of 10–15 Hz stimulation lead to two effects: (1) a local enhancement or potentiation of the driven afferent and (2) a generalised depression of the postsynaptic neurones.

Other lines of evidence also suggest that repetitive stimulation leads to some type of persistent and generalised depression of the postsynaptic cells. We have reported elsewhere[11] that long-term potentiation is accompanied by a persistent decrease in cell firing in response to glutamic acid applied by iontophoresis to the dendrites of the CA1 pyramidal cell.

Table 1 Comparison of population spike amplitude before and after tetanic stimulation

		Minutes post tetanus		
	Pre	5	10	15
Tetanised pathway	100%	390%	380%	332%
Control pathway	100%	74%	67%	73%
	$N = 17$	$N = 17$	$N = 17$	$N = 13$

All post-tetanic values were significantly different ($P < 0.05$) from immediate pre-tetanus values, as determined by a matched-pairs signed-ranks test.

In the absence of intracellular recordings we cannot dismiss the possibility that two intermingled sets of neurones are involved in the two effects, that the potentiation is localised to one set of cells and the depression to another. This seems unlikely, as it is quite evident from extracellular recordings that the same cells are driven by the two afferents used in our experiments. But whether we are considering opposing effects on a single neurone or in a small population of cells the present findings suggest that a kind of physiological modelling may go on in the hippocampus in which one afferent through repetitive firing gains at least a temporary priority at the expense of its neighbours. Finally, our results indicate that potentiation or depression of a pathway does not diminish the capacity of that system to undergo further plastic changes in response to subsequent episodes of repetitive stimulation.

Ethanol reduces excitatory postsynaptic current duration at a crustacean neuromuscular junction

ETHANOL potentiates the postsynaptic voltage response to acetylcholine at mammalian and amphibian neuromuscular junctions[1–4], by prolonging the duration of the postsynaptic conductance change[5–7]. At these synapses, hyperpolarisation also increases the time constant of decay (τ) of end-plate currents[8–14]. Because of this voltage sensitivity, it was proposed[15] that the rate-limiting reaction in the decay of end-plate currents involves the relaxation of membrane proteins, which undergo a change in dipole moment normal to the field direction as they change conformation. The magnitude and direction of the change in dipole moment then determines the effect of electric field on α, the reaction rate. α ($=\tau^{-1}$) would be proportional to $\exp(V\mu)$ (ref. 15) where V is membrane potential and μ the dipole moment change normal to the field direction. It has been suggested that the prolonged decay of end-plate currents produced by ethanol is due to increase by ethanol of the dielectric constant of the environment of receptors[6], which lowers the rate of reactions involving a decrease in dipole moment[16] and hence increases τ. In some arthropods, including crayfish, crab and locust, there is evidence that glutamate acts as an excitatory transmitter at neuromuscular junctions[17,18]. Also, the decay of excitatory postsynaptic currents in crayfish[19] and locusts[20] has the opposite voltage sensitivity to that found at amphibian neuromuscular junctions: hyperpolarisation reduces τ, suggesting that the rate-limiting reaction in the decay of conductance at these 'glutamate' synapses could be associated with a change in dipole moment which is opposite to that seen at amphibian neuromuscular junctions. Ethanol could then have an opposite effect at these two types of synapse, and depress synaptic transmission at glutamate synapses. We report here results of our study of spontaneous miniature excitatory junctional currents (MEJCs) in the crab, which confirm this hypothesis.

We studied the opener muscle (abductor of the dactyl) of the walking legs of the crab (*Scylla serrata*). Dissected muscles were continuously perfused with crab solution containing 466 mM NaCl, 8 mM KCl, 20 mM $CaCl_2$, 12 mM $MgCl_2$ and 10 mM $NaHCO_3$, *p*H 7.45 (ref. 21). Temperature was controlled to within 0.5 °C in the range 10–22 °C. The time course of decay of MEJCs was determined by recording extracellular potentials with low resistance (0.2–1 MΩ) electrodes (filled with 1 M NaCl) which were located focally over junctional regions. In some experiments, intracellular microelectrodes (3 M KCl) were used simultaneously to record membrane potential. MEJCs, which occurred at a low frequency (sometimes $> 1\ \text{min}^{-1}$) were recorded (using a Neurograph-N3 digital transient recorder), displayed on an oscilloscope screen and photographed.

Although the shape and duration of MEJCs varied, two distinct types were recorded. The 'fast' MEJCs examined here had a rapid growth phase (0.2–0.5 ms), then a slower decay lasting 2–5 ms at 20 °C (Fig. 1*A*). The other, 'slow' MEJCs, not studied here, had a variable, slower growth phase followed by a much slower, non-exponential decay phase lasting < 50 ms. The decay of most of the fast MEJCs could be described by a single exponential function, as at amphibian neuromuscular junctions (Fig. 1*B*)[11,12,22]. Similar MEJCs recorded from crab neuromuscular junctions have been described previously[23,24].

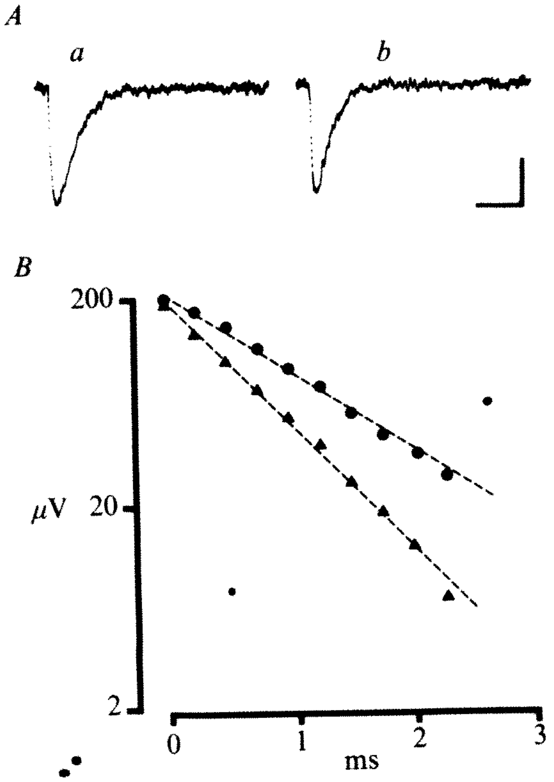

Fig. 1 Ethanol increases the rate of decay of MEJCs. *A*, MEJCs recorded in normal crab solution (*a*) and in the presence of 0.25 M ethanol (*b*). Calibrations: vertical, 100 μV; horizontal, 2 ms. *B*, semilogarithmic plot of the decay of MEJCs in control solution (●) and in 0.25 M ethanol (▲).

Recordings of these MEJCs were obtained in six preparations from cells with resting membrane potentials of −65 to −75 mV. The mean time constant of decay (τ) at 20 °C was 1.2±0.05 ms (mean±s.e.m.). The time constant of decay was temperature-sensitive, having a Q_{10} of approximately 2.0 in the temperature range 12–22 °C. The latter observation suggests that the decay of MEJCs is not rate-limited by diffusional loss of transmitter, a process which would be expected to have a lower Q_{10}. Ethanol (0.25 M) caused an obvious and reversible decrease in τ which is illustrated (trace (*b*) in Fig. 1*A*. The decay of MEJCs in ethanol remained exponential (Fig. 1*B*). In 0.25 M ethanol, τ was reduced from 1.2±0.05 to 0.5±0.02 ms, a 58% reduction. Lower concentrations of ethanol produced a smaller reduction in τ. The concentrations tested did not significantly change the membrane potential of the muscle fibres. Concentrations of ethanol, which at amphibian and mammalian neuromuscular junctions cause a significant increase in the duration of postsynaptic currents[5–7], produce a significant decrease in the duration of postsynaptic currents at crab neuromuscular junctions.

The results are consistent with the idea that effect of ethanol on the time course of postsynaptic currents is related to the change in dipole moment of the receptor during the reaction. The opposite voltage sensitivity of τ seen at glutamate-sensitive synapses[19,20] could reflect opposite changes in dipole moment, and this could be the explanation for the opposite effects of ethanol. There is no direct evidence for the same voltage sensitivity at the crab neuromuscular junction, but in preliminary experiments we observed that the rate of decay of MEJCs is slowed when the membrane is depolarised by increasing extracellular potassium concentration. It can be calculated[6] that an increase in dipole moment of about 40 debye in relaxing receptors would give the voltage sensitivity of τ seen at locust neuromuscular junctions[20]. This is similar in magnitude but in the opposite direction to the change in dipole moment calculated for amphibian neuromuscular junctions[6]. At toad neuromuscular junctions, 0.1 and 0.25 M ethanol increase τ by factors of 1.4 and 2.1, respectively[6]. It is interesting that at the crab neuromuscular junction we find that these concentrations of ethanol reduce τ by factors of 1.7 and 2.3, respectively. This agreement further supports the idea that ethanol could have a similar action at the two synapses, but that the sign of the change in dipole moment determines whether τ is increased or decreased. This explanation is not unique, and there are other possible ways in which ethanol could influence the rate of decay of synaptic currents differently at the two sites, for instance, by affecting differently the rate of dissociation of acetylcholine and glutamate from receptors if these reactions are rate-limiting.

The observation that ethanol can decrease τ at some synapses is interesting, as varied and selective actions of ethanol have been described previously in vertebrate and invertebrate nervous systems: ethanol potentiates cholinergic transmission at the amphibian and mammalian neuromuscular junction[1–4], and, conversely, has been shown to depress excitatory postsynaptic potentials in molluscan neurones[25,26]. It may be relevant that hyperpolarisation has been reported to increase the rate of decay of excitatory postsynaptic currents at some synapses in molluscan ganglia[27]. Ethanol also selectively depresses certain excitatory synapses in the central nervous system of goldfish without affecting other inhibitory and excitatory inputs[28], and depresses both inhibition and excitation of cat spinal motoneurones[29]. These depressant effects could arise from an increase in the rate of decay of postsynaptic currents, as seen at the crab neuromuscular junction. The reduction in amplitude of excitatory postsynaptic potentials caused by ethanol in molluscan neurones is associated with a reduction in their time to peak[26], probably due to an increase in the rate of decay of the underlying currents[30].

It is recognised that ethanol has anaesthetic properties. As many general anaesthetics reduce the time constant of decay of end-plate currents in amphibia and mammals, it has been suggested[31–33] that they may cause anaesthesia through a similar action in the central nervous system, that is, depression of synaptic transmission caused by a decrease in the duration of synaptic currents. A difficulty with this hypothesis has been that ethanol prolongs postsynaptic currents at the motor end-plate. We have now shown, however, that ethanol can reduce the duration of postsynaptic currents and hence depress transmission at a synapse where the transmitter is other than acetylcholine.

Asymmetrical currents and sodium currents in Ranvier nodes exposed to DDT

THE non-linear component of the capacity current (asymmetrical 'displacement current') of nerve membranes has been thought[1–3] to result from the movement of intrinsic membrane charges gating the specific pathways for sodium ions ('Na channels'). This interpretation is partly based on the observation that the voltage-dependent relaxation time constants of the sodium activating mechanism roughly agree with those of the displacement currents. According to this hypothesis, a similar correlation should be demonstrated when the kinetics characteristics of the Na system are modified under controlled experimental conditions. In this respect, the insecticide DDT is a useful tool as it slows down the turning-off of the Na-permeability of the nodal membrane[4,5] without changing the rate of its turning-on. We have therefore compared the relaxation time constants of both the sodium current activation and the displacement current on DDT-treated Ranvier nodes. The results suggest that the intramembrane charge movement is not the sole transition involved in the gating process of the Na channels.

Experiments were carried out on voltage clamped myelinated fibres of the frog *Rana esculenta*. The delayed K current was abolished by tetraethylammonium (TEA, 10 mM) and by replacing the axoplasmic K content by caesium. The displacement currents (I_d), recorded in the presence of tetrodotoxin (TTX, 10^{-6}M), were obtained by subtracting the linear (leakage and capacity) current components in response to hyperpolarising voltage pulses from the responses to symmetrical depolarisations. Fifteen identical pulses were alternatively applied in both directions (starting from a holding potential of $E = -100$ mV) and the corresponding currents were digitised and averaged. DDT, first dissolved in ethanol, was diluted to 10^{-4}M in Ringer solution. Ethanol was present in the final DDT-test solution at a concentration of 2%, so was added at the same concentration, to the 'control solution' (Ringer + TEA + ethanol 2%). As a rule, the sodium current (I_{Na}) and the displacement currents (I_d) were first recorded in the reference solutions (control solution without and with TTX respectively). The nodes were then superfused with DDT-test solution for 20 min and the I_{Na} records were taken. Immediately afterwards, the TTX-control solution was re-admitted into the chamber and I_d was recorded. Taking advantage of the irreversibility of the DDT effects[5], this latter procedure permitted measurement of both I_{Na} and I_d after the same time of exposure to DDT. At the end of the experiment, the ability of the nodes to conduct I_{Na} and the persistence of the DDT effects were verified in the control solution.

In our experimental conditions, the effects of DDT on I_{Na} were in good agreement with those previously reported[4,5]. For reference, Na current records are presented in Fig. 1 *a* and *b*. They confirm that a long-lasting tail of Na current remains after repolarisation, indicating that in DDT-poisoned nodes a fraction of the Na channels remain activated for a long time. The time course of both the turning-on and the turning-off of the I_{Na} activation were plotted against time, assuming that I_{Na} is proportional to the m^3h product (Hodgkin–Huxley variables). The turning-on of the sodium activation is described by a single exponential function with a time-constant

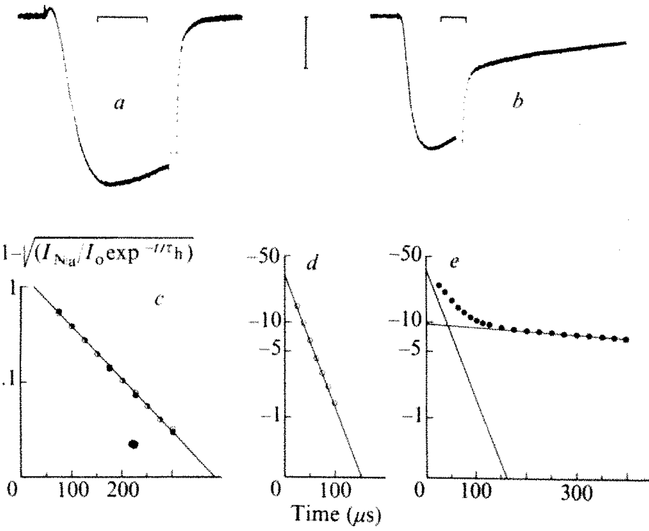

Fig. 1 Sodium current during 100 mV depolarising pulses from a holding potential of −100 mV. *a*, Before DDT and *b*, after exposure to DDT. Capacity and leakage currents were compensated analogically. Vertical and horizontal bars represent 5 nA and 200 µs respectively. Note the large tail of inward current in (*b*). The difference in the Na-current peak amplitude in (*a*) and (*b*) was not regularly observed. Graphs *c*, *d*, *e* are semilogarithmic plots obtained from the current records (*a*) and (*b*). At the onset of the depolarisation (*c*), before DDT (○) and after DDT (●). At repolarisation to the holding level, before DDT (*d*), after DDT (*e*). The straight lines in (*b*) represent the two exponential components giving the best fit to experimental points. Time constants of the single exponential functions: $\tau_m = 85$ µs (*c*); $\tau Na_{off} = 31$ µs (*d*); $\tau Na_{off,1} = 32$ µs (fast component in *e*); $\tau Na_{off,2} = 1390$ µs (slow component in *e*). Temperature 12 °C.

$\tau_m = 85$ µs which is unaffected by DDT (Fig. 1*c*). Under normal conditions (Fig. 1*d*) the turning-off can also be described by a single exponential with another time constant $\tau Na_{off} = 31$ µs. When DDT is added to the external medium (Fig. 1*e*), the tail of Na current is fitted by the sum of two exponentials: a fast one ($\tau Na_{off,1} = 32$ µs) very similar to that of Fig. 1*d*, and a much slower one ($\tau Na_{off,2} = 1390$ µs). This indicates that a fraction of the channels is unaffected by DDT whereas the rate of turning-off of the other fraction is nearly 45 times slower. From the extrapolated values of I_{Na} to time zero (t_0) in Fig. 1*e*, it may be deduced that, at the end of the depolarising pulse, 21.4% of the channels were affected in this experiment.

Figures 2 *a* and *b* represent the displacement currents obtained from the same fibre and at the same membrane potential as in Fig. 1. The analysis of these currents reveals that DDT does not affect the on-response of the displacement current (Fig. 2*c*) as expected from the results presented in Fig. 1*c*. However, the time constant $\tau d_{on} = 113\ \mu s$ is 1.3 larger than τ_m. Furthermore, the amount of displaced charges $[Q_{on} = I_{d,to}\,\tau d_{on}\,(1-e^{-t/\tau d_{on}})]$ is estimated to be 71 fC and is unaffected by DDT. In the absence of this agent (Fig. 2*d*) the time constant τd_{off} of the displacement current at the repolarisation is 42 μs (that is, 1.3 times larger than the corresponding Na_{off}). The amount of transferred charges ($Q_{off} = I_{d,to} \times \tau d_{off} = 55$ fC) is smaller than that transferred at the onset of the depolarisation. After exposure to DDT (Fig. 2*e*), two exponential components can be distinguished in the I_d off-response: a fast one ($\tau d_{off,1} = 42\ \mu s$), similar to that obtained from the control experiment, and a second one, markedly slower, with a time constant $\tau d_{off,2} = 190\ \mu s$. This second component is supposed to correspond to the fraction of charges affected by DDT. The best fit to the averaged points in the record of Fig. 2*b* leads to an estimate of the fractions of transferred charges ($Q_{off\infty,1}$ and $Q_{off\infty,2}$) of 28 fC (unaffected) and 27 fC (affected by DDT) respectively. The sum of both (55 fC) is identical to the amount of charges displaced at repolarisation under normal conditions.

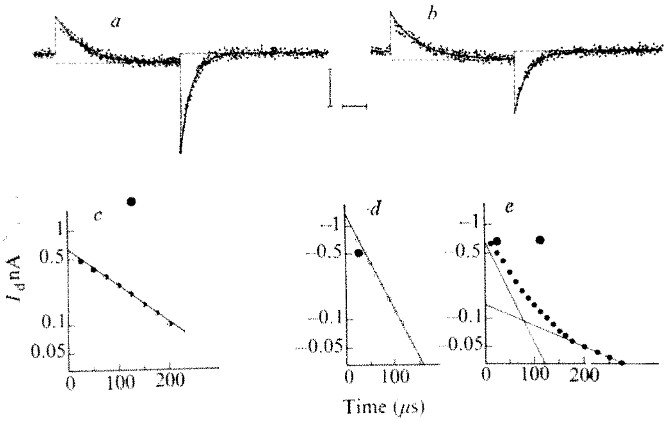

Fig. 2 Averaged displacement currents obtained from the same fibre as in Fig. 1 in response to 100 mV depolarising and hyperpolarising pulses from a holding potential of −100 mV. *a*, Before DDT and *b*, after DDT. Vertical and horizontal calibrations: 0.5 nA and 100 μs. The lines through the points represent the mean values taken as reference for the analysis presented in (*c*), (*d*) and (*e*). The small inward current component during the pulses is probably due to non-linearity of the leakage current between $E = 0$ and $E = -200$ mV or to discrete anodal breakdown during the hyperpolarising pulses; for this reason the zero-current reference for the on-response was taken at the end of the pulses. Graphs *c*, *d* and *e* are semilogarithmic plots of the I_d on (*c*) and off (*d*, *e*) responses, before DDT (○) and after DDT (●). The straight lines in (*e*) represent the two exponential functions: $\tau d_{on} = 113\ \mu s$ (*c*); $\tau d_{off} = 42\ \mu s$ (*d*); $\tau d_{off,1} = 42\ \mu s$ (fast component in *e*); $\tau d_{off,2} = 190\ \mu s$ (slow component in *e*). Estimated amount of displaced charges: $Q_{on} = 71$ fC (*c*); $Q_{off} = 55.3$ fC (*d*); $Q_{off\infty,1} = 28$ fc (fast component in *e*); $Q_{off\infty,2} = 27.2$ fC (slow component in *e*). Temperature 12 °C.

From a qualitative point of view, the effects of DDT on the displacement currents are those expected from the analysis of the sodium current, in particular when considering that DDT leaves the on-responses unchanged while the off-responses are altered. Thus, our results support the idea that the displacement current reflects the movement of charges involved in the activation process of the Na-conductance. Moreover, it appears that DDT acts only on charges previously displaced by depolarisation and at the time of reversion to their resting state (or position).

The fact that the fraction of charges affected by DDT (50% of the total amount in the experiment reported here) is larger than the fraction of affected channels (21%) is consistent with the assumption that at least two independent charges are involved in the gating subunit of each channel. If one assumes two particles per channel, only the channels in which both charged particles are affected by DDT will close slowly; those in which only one particle is affected will close at the same rate as intact channels.

A striking result is the observation that DDT increases the relaxation time constant of the I_d off-response by a factor of only 4.5 whereas it enhances that of the Na current by a factor of about 45. This indicates that the channels remain open for an appreciable time after the reversion of the gating charges to their resting configuration. This may be due to a specific effect of DDT. Disagreements between τd_{off} and τNa_{off} have been also observed, however, in squid axons submitted to external solutions made with heavy water[6]. Furthermore, discrepancies between the voltage dependence of the m-process and the displacement current have been reported for the squid axon[6] as well as for the Ranvier node[7] under normal conditions. There is thus good reason to suppose that DDT exaggerates the relaxation time of a further transition[6,8], complementary to the charge displacement and necessary for the closing of the Na channels.

We thank Dr B. Rudy for suggesting DDT experiments. This work was supported by the DGRST and CNRS.

Effect of transplantation of pancreas on development of hypothalamic obesity

HYPOTHALAMIC obesity is a syndrome of hyperphagia and obesity that follows destruction of the ventromedial region of the hypothalamus. This syndrome is associated with loss of normal nocturnal rise in food intake and with several endocrine changes of which increased concentrations of insulin are the most important. It remains to be settled, however, whether the hyperphagia or hyperinsulinaemia is the primary factor in the development of hypothalamic obesity. The aim of the present experiment was to distinguish between these possibilities by freeing the insulin-secreting islets of Langerhans from neural control. This was done by implanting foetal pancreatic tissue under the kidney capsule of diabetic rats. This experiment prevented the characteristic hyperphagia and obesity seen in the control animals with normally innervated pancreatic tissue.

Obesity can be produced by several experimental procedures[1]. Among the most widely studied is the one due to damage to the ventromedial region of the hypothalamus[2,3]. For many years, hypothalamic obesity was ascribed to the destruction of a 'satiety centre' which was thought to coincide anatomically with the ventromedial nucleus of the hypothalamus[4]. Ablation of this 'satiety centre' was believed to remove the inhibitory influences from a primary feeding centre in the lateral hypothalamus and allow excess feeding.

Recent investigations have suggested, however, that this interpretation may be incorrect[5,6], and alternative hypotheses have been proposed. One of these suggests that the increase in food intake and obesity are both secondary to the rise in insulin levels which follow ventromedial hypothalamic (VMH) injury. The present studies were designed to critically examine this hypothesis.

An increase in the concentration of serum insulin after a VMH lesion is among the earliest observed changes[7,8], and occurs even when the food intake is limited and the increase in body weight is prevented[9,10]. If the increase in insulin is inhibited by destroying the β cells in the pancreas which produce insulin, the effects of a ventromedial hypothalamic lesion on food intake and body weight are abolished or largely reduced[11,12]. In addition, it is well known that injections of insulin will increase food intake and body weight[13]. This constellation of findings suggests an important role for insulin, but leaves unsettled the mechanism for its increase. Two possible hypotheses may be advanced. One is humoral, postulating that a 'hypothalamic factor' is released into the circulation and directly stimulates the release of insulin[14,15]. The other hypothesis proposes a neural mechanism[16]. A critical test of these two hypotheses might result from placing hypothalamic lesions in rats whose pancreatic islets were no longer under the neural influences of the pancreatic bed.

Female rats of the highly inbred Lewis strain weighing approximately 200 g were injected with streptozotocin (65 mg kg^{-1}). Four to seven days later, the diabetic rats (overnight fasting blood glucose levels >250 mg dl^{-1}) received transplants of pancreatic tissue from six foetuses which averaged 16–17 d old[17]. These transplants were placed beneath the renal capsule and the animals were observed for 4 weeks. The rats with effective transplants showed a gradual decline in serum and urine glucose and the insulin requirement disappeared. After 3 weeks of normal serum glucose, the recovered rats were tested for the function of the transplanted pancreatic tissue by giving them an intraperitoneal challenge with glucose (1 g kg^{-1}). The increase in serum glucose was similar in transplanted and control animals. Bilateral ventromedial hypothalamic lesions or sham-operations were introduced in the transplanted and control animals. Bilateral ventromedial hypothalamic lesions were produced using previously described coordinates[18] (at the Bregma anteriorly; ±0.7 mm lateral to midsagital line; and 1.0 mm above the base of the skull). Six of the eight control (non-transplanted) rats and five of the seven rats with pancreatic transplants had adequate hypothalamic lesions as confirmed by histological examination of stained sections of the brain. Data on body weight, the Lee index for body fatness at the final week and food intake measured two weeks after VMH lesions were compared using an analysis of variance with multiple range comparisons.

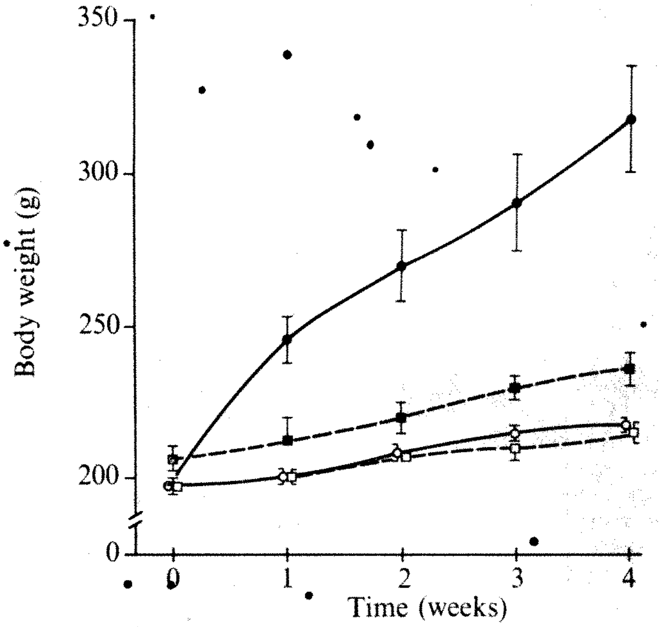

Fig. 1 Body weight of transplanted (■, □) and intact rats (●, ○). Body weight was followed for 4 weeks after VMH (●, ■). ○, □, Sham-operated. The increase in the lesioned rats without pancreatic transplants was statistically significant. The rats with pancreatic transplants and VMH lesions gained slightly, but not significantly more weight than the sham-transplanted animals. All data are presented as the mean ± s.e.m.

Body weight rose an average of 120 g in the lesioned rats with normal pancreatic tissue (Fig. 1) and reached an average of 319 g 4 weeks after the VMH lesions. The two groups of sham-operated rats (both with and without transplanted pancreatic tissue), showed a significantly smaller rise in weight than the VMH-lesioned rats with normal pancreatic tissue. There were no significant differences in the weight gain between VMH-transplanted rats and sham-operated animals. The Lee index, when the animals were killed, was used to measure fatness. It showed a significant increase in body fat in the control rats with VMH lesions, but no differences in body fat in the other groups, including the lesioned rats with transplants (Table 1). Food intake increased 71% in the lesioned rats with the normal pancreases but only 23% in the lesioned rats with transplanted tissue. The diurnal pattern of food intake was also measured during the third week after VMH operation. The ratio of food intake between 0900 and 1800, and between 1800 and 0900, was 3.3/14.5 and 3.1/14.3 for the two sham-lesioned groups. In the VMH-lesioned rats with normal pancreas, this ratio was 10.1/18.9. In the VMH-lesioned rats with transplants, the ratio was 6.0/14.9.

The results of the present experiment show that: removal of the pancreas from its usual neural influences markedly reduced the effect of ventromedial hypothalamic lesions on body weight and food intake; and that release of a humoral factor directly from the hypothalamus is not a sufficient

Table 1 Food intake and fatness of rats with transplanted pancreatic tissue, with or without hypothalamic lesions

explanation for the high food intake and weight gain in rats with VMH lesions.

The vagus and sympathetic nerves both provide neural connections to the pancreas. The finding of gastric hypermotility and hyperacidity in rats with hypothalamic obesity suggests that the firing rate of the vagus nerve may be enhanced either directly or indirectly after VMH injury[19]. Further support for a role of the vagus nerve was provided by Powley and Opsahl who showed that vagotomy reversed the hypothalamic obesity[16] and by the fact that stimulation of the vagus increases insulin secretion[20,21]. The finding of a correlation between the level of acid in the stomach and the concentration of insulin in the serum of rats which had VMH lesions and varying degrees of vagotomy also suggest that the enhanced activity of the vagus nerve plays an important role in the syndrome of hypothalamic obesity[18].

The sympathetic nerves are also known to modulate insulin secretion from the pancreas[22,23]. Whether lesions in the ventromedial hypothalamus modify both components of the autonomic nervous system or only one remains to be established. What seems clearly demonstrated by the present experiment is that primary neural innervation of the pancreas plays a central role in the development of the increased food intake and obesity that follow ventromedial hypothalamic injury.

We thank Dr Donald Novin, Department of Psychology, UCLA, for assistance with the histological preparation of the brains. This work was supported in part by the NIH.

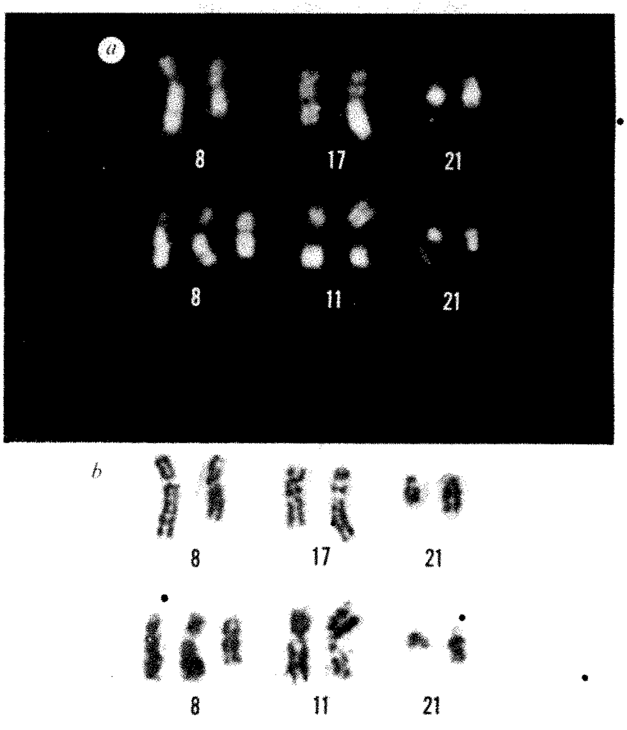
Comparable complex rearrangements involving 8;21 and 9;22 translocations in leukaemia

FOR many years chromosomal abnormalities in tumours seemed to be so variable that it seemed most reasonable to view them as epiphenomena. But banding techniques have revealed non-random chromosomal abnormalities in several human and mammalian malignancies. The observation of relatively consistent translocations in several types of leukaemia and lymphoma lends credence to Boveri's hypothesis[1] that chromosomal alterations are among the fundamental changes that result in malignancy. For example, the Philadelphia (Ph^1) translocation[2] is observed in 85–90% of patients with chronic myelogenous leukaemia (CML), and the 8;21 translocation is observed in 10–15% of patients with acute myelocytic leukaemia (AML)[3,4]. We report here that, when more complex structural changes occur, comparable patterns of rearrangements are found for both the 9;22 and the 8;21 translocations. This provides further support for Boveri's hypothesis.

The common rearrangement in AML involves a translocation of about one-third of the long arm of chromosome no. 8 to the end of no. 21 [t(8;21)(q22;q22)] (ref. 3). This rearrangement is often associated with loss of a sex chromosome, an X in female or a Y in male patients, which is otherwise a very rare occurrence in acute leukaemia. Whereas the original report[3] and subsequent confirmations[4] identified rearrangements involving only nos 8 and 21, we observed a variant translocation in a female patient with AML, in whom the translocation from no. 8 involved the end of the long arm of no. 17, and in whom there was an associated loss of an X chromosome (Fig. 1)[5]. Analysis with fluorescence revealed this abnormality in 22 of 26 cells (85%) obtained from the initial pretherapy sample and in 5 of 10 cells (50%) in a sample obtained 2 weeks later, while the patient was receiving chemotherapy.

A second female patient with a variant has been identified; the translocation from 8q involved the end of the short arm of no. 11 without loss of one X, but with the addition of one no. 8. In this patient, one no. 21 appeared larger than normal because of the presence of a narrow dull band of fluorescent material, presumably band 11p15 [47,XX,+8,t(8;11;21)(q22;p15;q22)] (Fig. 1). The complex

Fig. 1 Partial karyotype of cells from two patients. *a*, Stained with quinacrine; *b*, stained with Giemsa. Top row, chromosome nos 8, 17 and 21, showing the deletion of 8q22, transfer of this material to 17q23?, and the additional material on 21q presumably representing the end of 17q(q23→qter). Bottom row, chromosome nos 8, 11 and 21, showing the presence of two normal chromosomes no. 8 and the deletion of the third at 8q22, transfer of this material to 11p15, and the additional band on 21q presumably representing 11p15→pter.



translocation was seen in 4 of 18 cells (22%) in the pretreatment sample and in 13 of 14 cells (93%) in the sample obtained 10 d later.

Re-examination of the previous patient with the 8;17 translocation showed an analogous aberration of no. 21, compatible with a translocation from 17q (band 23?); the corrected karyotype should be 45,X,t(8;17;21)(q22;23?;q22). The break points in nos 8 and 21 in these two cases were similar to those in the standard 8;21 translocation.

The relevance of these observations to the role of chromosomal changes in leukaemia becomes apparent when one considers variant translocations in patients with Ph^1 positive CML. In most of these patients, a portion of the long arm of no. 22 (Ph^1 chromosome) is translocated to the end of the long arm of no. 9; this type of translocation was observed in 413 of 440 patients whose cells have been examined with banding[6]. Of the 27 cases with other rearrangements, 15 had translocations affecting three chromosomes; in each instance, two of the three chromosomes involved were nos 9 and 22, with the standard break points. Most of the remaining patients showed a translocation between no. 22 and some chromosome other than no. 9. Thus a parallel exists between the chromosomal changes in CML and in AML. In each case, two chromosomes are preferentially involved in a translocation; in some cases three chromosomes are affected, two of which are those involved in the typical translocation.

The mechanism producing such specific chromosomal rearrangements remains an enigma. Whether it is related to proximity in the nucleus or to homologous sequences of DNA, or whether it is the result of some selective advantage, is unknown. The observation of similar 'rules' governing two different translocations in two different types of leukaemia suggests that these changes are subject to precise, although as yet undetermined controls, and lends support to Boveri's hypothesis that chromosomal changes are among the fundamental alterations associated with malignancy.

Derepression of *E. coli trp* operon on interfamilial transfer

THE P-group R factor RP4 originally isolated from *Pseudomonas aeruginosa* can be transferred to many Gram-negative bacteria[1–3]. In spite of its large molecular weight, RP4 has only one site susceptible to each of *Eco*RI (ref. 4), *Hind*III (ref. 5) and *Bam*NI (data not shown) restriction endonucleases. We have constructed an RP4-*trp* plasmid consisting of RP4 DNA and the complete tryptophan operon of *E. coli* obtained from bacteriophage λ*trpE-A*$_{60\text{-}3}$ *in vitro*[6]. We reported that the tryptophan synthetase activity in the strain carrying RP4-*trp* plasmid was repressed by exogenous tryptophan[7]. Manson and Yanofsky have reported that the *E. coli trp* operon on the colVB plasmid was similarly regulated in other enteric species[8]. We show here that the RP4-*trip* plasmid in *E. coli* can be transferred by conjugation to *Pseudomonas aeruginosa* which belongs to a different family from *E. coli*, converting *Pseudomonas* Trp$^-$ phenotype to Trp$^+$. The levels of tryptophan-synthesising enzymes in *P. aeruginosa* carrying RP4-*trp* plasmid are much higher than those in the wild strain, and they are not controlled by the repression system in *P. aeruginosa* cells.

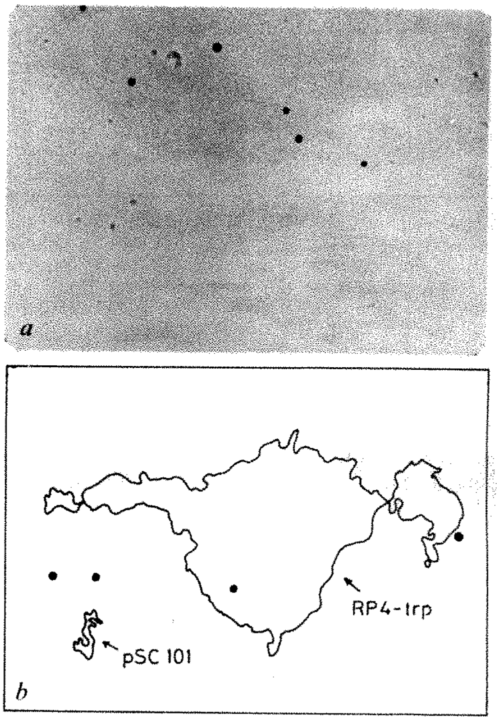

Fig. 1 Electron micrograph of RP4-*trp* DNA obtained from *P. aeruginosa* M12. pSC101 (molecular weight 5.8 × 10^6) was shown as internal standard. RP4-*trp* DNA was calculated to be of 48 × 10^6 molecular weight.

Table 1 shows that the transfer frequency of RP4–*trp* plasmid from *E. coli* cells to *P. aeruginosa* cells was lower by two orders of magnitude than that between *E. coli* $r^-_K m^-_K$ strains, whereas the transfer frequencies of RP4–*trp* from *E. coli* to *P. aeruginosa* for Trp$^+$ and Carb^R markers are almost equal (Table 1), implying that the low frequency is due to the presence of a restriction systems or some other mechanisms in *P. aeruginosa* cells but not to the inactivity of *trp* operon of *E. coli* in *P. aeruginosa*. So far, all the transformants selected for resistance to carbenicillin were also tryptophan independent and vice versa.

Activities of two enzymes belonging to tryptophan operon, anthranilate synthetase (ASase) and the β subunit of tryptophan synthetase (TSase) were measured in crude extracts of cells grown in non-repressed or repressed condition (Table 2). The levels of both enzymes in the *P. aeruginosa* M12 strain (PAO subline) carrying RP4–*trp* plasmid were markedly elevated compared with those in a wild *P. aeruginosa* PAO strain which has chromosomally-located *trp* genes, and showed almost equal enzyme activities in both non-repressed and repressed conditions.

Calhoun *et al.*[9] reported that in wild-type *P. aeruginosa*, the presence of exogenous L-tryptophan during growth in a minimal salts–glucose medium had no influence on the specific activities of ASase, 5-phosphorylribose 1-pyrophosphate phosphoribosyl transferase, N(5′-phosphoribosyl) anthranilate isomerase and indoleglycerol 3-phosphate synthetase in the cells, whereas their real repressibility by

Table 1 Transfer frequency of RP4-*trp* plasmid

Donor	Recipient	Selection	Transfer frequency
E. coli C600 $r^{-}_{\mathrm{k}}m^{-}_{\mathrm{k}}trp^{-}$ (RP4-*trp*)	*E. coli* C600 $r^{-}_{\mathrm{k}}m^{-}_{\mathrm{k}}trp^{-}str^{\mathrm{R}}$	Trp^{+}	1.7×10^{-2}
		Carb$^{\mathrm{R}}$	1.3×10^{-2}
E. coli C600 $r^{-}_{\mathrm{k}}m^{-}_{\mathrm{k}}trp^{-}$ (RP4-*trp*)	*P. aeruginosa* M12 str^{R}	Trp^{+}	1.8×10^{-4}
		Carb$^{\mathrm{R}}$	1.2×10^{-4}

Donors and recipients were middle log-phase cultures grown in nutrient broth supplemented with 0.4% KNO_3 without shaking at 37 °C. 0.5 ml of a donor culture was mixed with 2.5 ml of a recipient culture with 2.0 ml of fresh broth and this mixture was incubated at 37 °C for 2 h without shaking, then an aliquot was plated on the streptomycin (100 µg ml^{-1}) containing Vogel and Bonner's minimal medium in the absence of tryptophan, or in the presence of tryptophan (Trp, 50 µg ml^{-1}) and carbenicillin (Carb, 500 µg ml^{-1}) for transfer to *E. coli*. Appropriately supplemented (as above) glutamate minimal medium[10] was used for transfer to *P. aeruginosa*. The frequency of transfer was calculated as number of transfers per donor cell. Strains used were *E. coli* C600 $r^{-}_{\mathrm{k}}m^{-}_{\mathrm{k}}trp^{-}$ (RP4-*trp*), restriction and modification minus *E. coli* C600 $leu^{-}thr^{-}thi^{-}trp^{-}$ containing RP4-*trp*; *P. aeruginosa* M12 (ref. 10), *trp*.

exogenous tryptophan were revealed only in tryptophan auxotrophic mutants which caused the strict deprivation of intracellular tryptophan in depressed culture condition. In contrast the TSase activities in *P. aeruginosa* were much reduced in the presence of exogenous tryptophan and induced by their substrate indoleglycerophosphate. Our data on PAO (wild type) strain are consistent with their observations, but a striking difference exists in the specific enzyme activities of strain M12, which has received the complete *E. coli* tryptophan operon in the form of RP4–*trp* plasmid DNA. Strain M12 carrying RP4–*trp* showed much higher levels of both ASase and TSase activity, and neither enzyme was repressed by exogenous tryptophan.

The amount of RP4–*trp* DNA in *P. aeruginosa* measured on a CsCl–ethidium bromide density gradient was almost equal to that of RP4 DNA in the same host strain (data not shown), indicating that RP4–*trp* was limited in number as RP4. This confirms our assumption that the expression of the *E. coli* tryptophan operon was out of the control of the *P. aeruginosa* repression system.

The molecular weight of RP4–*trp* in *P. aeruginosa* was 48×10^{6} (Fig. 1), which was the sum of the RP4 DNA (38×10^{6}) and the tryptophan fragment (10.8×10^{6}) derived from $\lambda trpE$–$A_{60\text{-}3}$ DNA. The two bands, one corresponding to 10.8×10^{6} and the other presumably to 38×10^{6} daltons could be seen in agarose gel electrophoresis of *Eco*RI-digested RP4–*trp* DNA obtained from *P. aeruginosa* M12 cells (data not shown), showing that the complete *E. coli* RP4–*trp*[7] was transferred to *P. aeruginosa*. Together with the transfer experiments this shows that the RP4–*trp* DNA has not been changed by deletion or insertion during conjugation.

These results imply that the *trp* repressor protein of *P. aeruginosa* cannot bind to the *trp* operator region of *E. coli* and so the *trp* gene products are expressed constitutively. The *P. aeruginosa* Trp^{-} phenotype has been converted to Trp^{+} by the effective transcription and translation of the *E. coli trp* operon by the *Pseudomonas* system.

Manson and Yanofsky discussed the suggestion that the identical regulation of the *E. coli trp* operon in many of the Entero-bacteriaceae is proof of their common ancestry. The Family Pseudomonadaceae, however, seems to have diverged from the Family Enterobacteriaceae further back in evolution.

Table 2 Specific activities of tryptophan-synthesising enzymes in *P. aeruginosa* PAO1 wild type and M12 carrying RP4-*trp*

Strain	Trp	ASase	TSase β
PAO1	+	1.41	0.38
	−	1.53	2.17
M12 (RP4-trp)	+	6.59	19.0
	−	6.11	21.2

Cells were grown in glutamate minimal medium with or without tryptophan (100 µg ml^{-1}) and harvested in late exponential phase. The preparation of crude cell extracts and the assays for anthranilate synthetase and β subunit of tryptophan synthetase activities have been described[8].

These experiments were carried out using precautions corresponding to the P3 containment level suggested by the US National Institutes of Health. *P. aeruginosa* and *E. coli* are natural hosts of the RP4 plasmid, and the fact that the *E. coli trp* operon is translated effectively in *P. aeruginosa* prove that the translation codes are identical in these two organisms suggests that possibly dangerous 'unknown' proteins would not be produced by this combination.

We thank Miss T. Koshikawa for technical assistance. We also thank Dr M. Kageyama of this institute for discussions and for supplying *P. aeruginosa* PAO1 and M12 strains.

Correlation between the X-ray structure of melanostatin and its conformation in solution

THE establishment of correlations between solid-state (for example, X-ray) conformations and conformations in solution (monitored by spectroscopic methods such as nuclear magnetic resonance (NMR)) is essential for the understanding of structure–function relationships in biologically active molecules. The relative functional importance of static and dynamic structures is of particular interest for peptide hormones which reach their site(s) of action on the receptor via a fluid medium. We describe here a comparative study of melanostatin (Pro–Leu–Gly–NH_2) which acts as a melanocyte stimulating hormone release-inhibiting factor[1].

Melanostatin was chosen for study because its X-ray structure is known[2], its minimum energy conformations have been computed[3], and ^{1}H NMR studies in deuterated dimethylsulphoxide[4] and in aqueous solution[5] provide information about the time-averaged values of the dihedral angles in the backbone and side chains. We used ^{13}C NMR spin–lattice relaxation times[6] (T_1) of the proton-bearing carbons of melanostatin, in conjunction with a plausible theoretical model of molecular reorientation, to elicit dynamical information about the conformation in solution. The model for reorientational relaxation is stochastic rotational diffusion, with parameters optimised by a nonlinear least-square procedure[7,8]. From these one can estimate both the overall molecular tumbling rate in solution, and the rates of internal motion about individual bonds. Thus the T_1 data facilitate study of the relative flexibilities of the various molecular fragments.

We first attempted to correlate the ^{13}C NMR T_1 values obtained for melanostatin in aqueous solution with theoretical values calculated for the rigid X-ray structure. This rigid conformation was assumed to tumble about the three principal axes of its moment of inertia tensor with the optimal diffusion rate constants D_i. Even fully anisotropic ($D_1 \neq D_2 \neq D_3$) overall rotation of the rigid X-ray structure cannot account for all the observed T_1 values. This conclusion is unchanged even if the molecule is assumed to take on the unlikely fully extended conformation. Furthermore, the least-squares fit is not improved if the reorientation axes are chosen optimally rather than forced to coincide with the principal axes of the moment of inertia tensor. It was necessary to invoke internal motion for various molecular fragments in order to reproduce the observed T_1 values of melanostatin.

^{13}C T_1 values were measured in aqueous solution (50 mg ml^{-1}) using the inversion-recovery technique[9]. Complete nuclear Overhauser enhancements (NOE) were obtained for all proton-bearing carbons[10]. Table 1 shows ^{13}C T_1 values determined for Pro–Leu–Gly–NH_2 in which the prolyl residue is uncharged. Fig. 1 depicts molecular models of the folded and extended forms of the tripeptide we used in the calculation. The models are viewed along the C and B principal axes of the moment of inertia tensor for the folded and extended forms, respectively. The moments of inertia were calculated from the Cartesian coordinates of all the atoms[11]. The ORTEP thermal-ellipsoid plot programme for crystal structure illustration[12] was used to draw the figures. A nonlinear least-squares procedure[7,8] was used to determine optimal sets of anisotropic rigid body rotational diffusion constants D_i, using experimentally obtained T_1 values and the computed direction cosines of the corresponding C–H vectors. C–H distances were assumed to be either 1.09 Å, or the actual values deduced from the X-ray data; the qualitative conclusions do not depend on the choice of the C–H distances. Table 1 lists the optimal effective correlation times τ_i ($\tau_i = 1/6D_i$) for overall rigid anisotropic molecular reorientation about the principal axes of the moment of inertia tensor, as well as the T_1 values calculated with these correlation times. Results are shown both for the X-ray structure and the fully extended form.

When all proton-bearing carbons are included in the least-squares fitting, the T_1's of the α–carbons are matched reasonably well (within ±40%). T_1 values for the CH_2 groups in the proline ring and for the CH_3 groups of the leucyl residue, however, were only within a factor of 2–3 of the experimental values. It is reasonable to ascribe these discrepancies to flexibility within the pyrrolidine ring of proline[13] (probably puckering motion), and to rapid internal rotation of the CH_3 groups[14]. We repeated the calculations in the absence of these carbons. This led to τ_i values qualitatively the same as in the all-carbon case and which produced T_1 values for the α carbon of the prolyl, and the α, β, and γ carbons of the leucyl residue that were within the experimental uncertainties (±10%) of the measured T_1 values. Of special interest is the discrepancy between observed and calculated T_1 values for the glycyl residue. This is attributed to increased flexibility of this residue with respect to the remainder of the peptide backbone, a feature which is emerging as characteristic of glycyl residues[7].

The overall molecular tumbling of the X-ray conformation is not markedly anisotropic, having effective correlation times of 5.9, 7.5 and 3.0×10^{-11} s for rotation about the principal axes A, B and C of the moment of inertia tensor. Because the overall motion is nearly isotropic, displacement of the principal axes of the rotational diffusion tensor from corresponding axes of the inertia tensor would have little effect on calculated T_1. Calculations were repeated for a fully extended conformation in order to test the sensitivity of the calculated T_1 values to

conformational differences. Even though the overall fitting errors are comparable for the two conformations, the optimal sets of τ_i values are physically less reasonable for the extended form (in some instances spanning three orders of magnitude).

Having established that only internal flexibility can account for the observed T_1 values, we estimated optimal rates of internal rotation about individual C–C bonds. This was done both for the CH_3 groups and for the $C_\alpha^{(Leu)}$–$C_\alpha^{(Gly)}$ pseudo-bond[16] in the backbone. The values for the effective correlation times τ_A, τ_B, τ_C describing overall molecular reorientation of the X-ray conformation were the optimal values obtained fitting the backbone carbons only. Using an ellipsoid of rotation for the overall molecular shape, the effective correlation times we calculate for the CH_3 rotation ($\tau_{int} = 5 \times 10^{-12}$ s) and for rotation about the pseudo-bond ($\tau_{int} = 5.9 \times 10^{-11}$ s) are physically reasonable, further confirming the postulate of internal mobility. No attempt was made to estimate the rate and amplitude of puckering in the proline ring.

Correlating the X-ray structure with ^{13}C NMR relaxation data has shown that in solution Pro–Leu–Gly–NH_2 is not rigid on the NMR time scale. The T_1 data seem to be good qualitative monitors of internal mobility in linear peptides, and when interpreted on the basis of simple theoretical models of rotational reorientation, can identify and locate flexibility within the molecule. The overall molecular shape of peptides the size of melanostatin (and up to molecular weight ~1,000) has minor influence on the calculated rates of internal rotation about individual C–C bonds[15]. Thus side chain–side chain interactions and their influence on the mobility of adjacent residues in peptides and peptide hormones can be profitably studied using ^{13}C NMR relaxation measurements in solution, without the need for precise information on the overall molecular shape. Such studies, coupled with experiments on the influence of solvents on T_1 (which probe changes in mobilities or structure due to the changing environment), with rotamer population data derived from spin–spin coupling measurements, with proton–proton relaxation results, and with predictions from conformational calculations, can provide consistent dynamical information about peptides in solution and may enhance our understanding of structure–function or conformation–function relationships in peptide hormones.

We thank Dr P. L. Johnson for providing X-ray coordinates of melanostatin, and Drs W. M. Murphy, C. P. Huber and G. I. Birnbaum for computer programs.

matters arising

The 17-d periodicity of Cygnus X-3

ARIEL V observations have indicated[1] a possible 16.75-d periodicity in the flux of Cygnus X-3. I report here that the primary data (from ref. 1) have been digitised and power-spectrum analysed; the results are shown in Fig. 1. (Analysis details available from the author.) The power spectrum shows a broad continuum of fluctuations, with an r.m.s. variation ~ 40% of the average flux for periods $\gtrsim$ 3 d and a power law spectrum, $P(f) \propto f^{-1.5}$. This is not the spectrum expected from a shot-noise source[2].

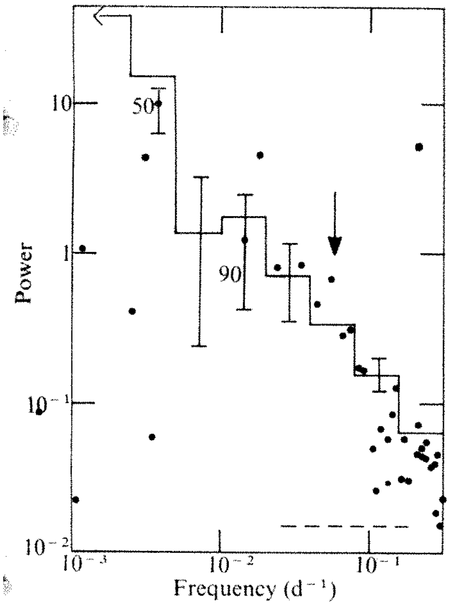

Fig. 1 Relative power spectrum of the flux of Cygnus X–3. Circular points are spectrum using FFT method (typical 50% and 90% confidence intervals are shown). The histogram gives spectrum using nested variance technique (90% confidence intervals shown). Dashed horizontal line represents noise level.

The arrow in Fig. 1 indicates a small peak in the power spectrum at the 16.75-d periodicity discussed in ref. 1. The significance of the peak is estimated from the excess power above the background fluctuation level (rather than above the Poisson noise level)[2]. There is about 50% likelihood that there exists a 16.75-d periodicity. This periodicity, if real, accounts for ~10% of the fluctuations and has an r.m.s. amplitude ~4% of the total flux.

HOLT REPLIES—Owens implies that the ~17-d periodicity reported in ref. 1 may be artefactual, in view of the broad continuum of fluctuations evident in the raw data. We have no quarrel with such a qualification; indeed, ref. 1 explicitly pointed out that the high degree of source variability, variable gaps in coverage, and no explicit correction for the known 4.8-h source modulation could be expected to result in artefactual frequency components in the data analysis.

The ~17-d effect was not, therefore, reported solely on the basis of it being the most significant (statistically) period in the search we performed on the Ariel V All-Sky Monitor data. We felt that the apparent presence of the same effect in the Ariel V Sky Survey Experimental data, which were corrected for 4.8-h variations and which were obtained during extended gaps in the All-Sky Monitor exposure (so that the two sets of data were completely independent), was sufficient justification for alerting the scientific community to the possibility of its reality. We regret that the quality of our data cannot support a stronger statistical argument for the presence (or absence) of a persistent ~17-d modulation of the variable Cyg X-3 intensity.

No new limit on size distribution of γ-ray bursts

Carter *et al.*[1] derived an upper limit to the (balloon) intensity of small γ-ray bursts at ≈ 100 below the extrapolated known size spectrum, and concluded that γ-ray bursts are of galactic origin. But we claim, for the following reasons, that their results are entirely consistent with the −1.5 index power-law extrapolation. There is, therefore, no conclusion regarding the nature or the origin of γ-ray bursts to be drawn from their measurements.

(1) Their selection criterion for candidate events was that of three successive 0.6-s increases in the γ-ray count rate. A study of all known bursts (data kindly supplied by R. W. Klebesadel) shows that this requirement ignores 75% of events due to their widely varying temporal nature.

(2) The total energy sought in 1.8-s does not represent the entire energy that would be found, for the same reason. The missing energy due to fluctuations is incorporated by reassigning the event size by a factor of ≈ 2.

(3) Observed γ-ray burst size spectra have been published[2,3] with the measured flux of each known event multiplied by 1.4 to 2, to include the emission below the satellite energy threshold, knowing the typical spectra[4–6]. Comparison data must normalise equivalently.

(4) The authors knowingly employed a 1-s.d. upper limit[1]. Small-number statistics demand the usual confidence limit of 95%, raising their upper limit by three.

(5) The observed fraction of the sky was apparently taken to be 0.5, ignoring atmospheric absorption at large zenith angles which would give an unobscured sky fraction of 0.25–0.3. This point is incorporated within the following considerations.

(6) The response of a horizontal, flat detector must distort the measurement of the burst size spectrum, even from an isotropic source distribution. For a totally absorbing detector it can be shown[7] that the average burst size $\overline{S}$ that contributes to the smallest events of apparent size $Z = S \cos\theta$, given an intrinsic spectrum $N(S)\,\mathrm{d}S = kS^{-\gamma}$, is

$$\overline{S} = Z\,[(\gamma-1)/(\gamma-2)]$$

$$\times\ [(1-\cos^{(\gamma-2)}\theta_0)/(1-\cos^{(\gamma-1)}\theta_0)], \quad (2)$$

with θ_0 the maximum equivalent unobscured zenith angle θ. Using their published detector characteristics[1], we find a required vertical shift of 2.2 and a horizontal shift of 1.3 on the size spectrum, including point 5.

The total combined effect is that the upper limit rederived from the data of Carter *et al.*[1] is raised up by two orders of magnitude, entirely consistent with the −1.5 index power-law extrapolation of the known size spectrum (Fig. 1). In fact, it is exactly an analogous threshold effect of lack of observation which depresses the Vela size spectrum low end by up to three orders of magnitude.

Even if (on the basis of no single-event observation) an upper limit below the −1.5 index extrapolation were found, this alone would not prove either the size spectrum model or the origin hypothesis suggested[1]. Such a result would imply only that the source distribution is not infinite in extent, assuming that the average absolute magnitude of emitters is independent of distance.

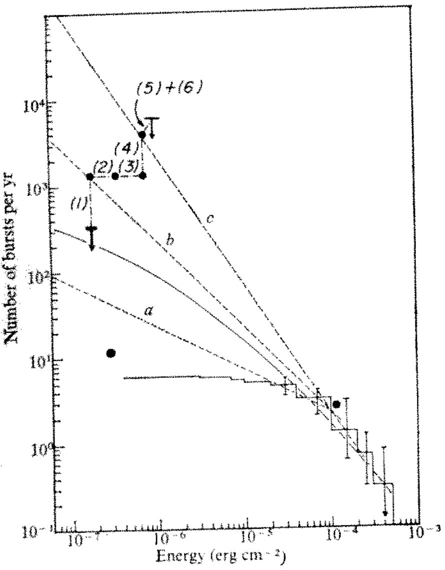

Fig. 1. The γ-ray burst results of *Carter et al.*[1], adjusted by six factors, numbered accordingly. Compare with Fig. 1 of ref. 1.

CARTER ET AL. REPLY—Cline and Schmidt[1] have presented a series of subjective arguments in an effort to show that our earlier reported upper limit to the rate of γ-ray bursts[2] can be made to conform with a hypothetical number–size spectrum with an index of −3/2. We believe that they have become too attached to this hypothesis. In fact, the data from the Vela satellite is equally consistent with an index of −2, although this does not have the same cosmological attraction. If the power-law index were −3/2 then a detector with an energy of 10^{-7} erg should record a burst approximately every 2 h or so. No such evidence exists.

Our criterion for the recognition of γ-ray bursts was that the counting rate in each of three consecutive, and independent, measurements should exceed the background by 3σ. Unless one has a coincidence in a second, remote, sensor it would seem imprudent to claim excesses in a single measurement interval to be a genuine γ-ray burst. There is evidence of some poorly understood events in which anomalous increases arise in a single resolution element as well as effects which lead to the occasional saturation of a complete telemetry frame[3,4]. Since the basic resolution time in our particular experiment was 0.6 s, an intrinsic limit of 1.8 s is set in our burst search. Although our main data analysis was confined to the above selection criterion, we did in fact search for possible shorter events. In this case, however, we required a coincidence in the counting rate from at least two of the differential energy channels. No evidence for γ-ray bursts was detected using this criterion either.

We had not discussed the rationale of our selection criterion nor the details of our analysis methods, in our original brief contribution since they are fairly standard procedures.

In the following sections we comment on the numbered points raised by Cline *et al.*

(1) From the existing published data[5,6] it may be seen that the typical size for a γ-ray burst is 3–5 s and the first peak lasts ~2 s. The temporal variations seem to be of the same magnitude as the basic time resolution of the particular experiment. Our selection criterion, therefore, will be met by a substantial majority of these events. We will, admittedly, lose those events having a duration ⩽1 s but we estimate this loss to be about 20% of the total.

(2) The limit shown in our figure corresponds to the selection criterion outlined above. We could have set a lower energy limit had we considered only longer bursts. But, since the typical length of γ-ray bursts is longer than our measurement interval and since the average intensity represents the first moment of the generating function, the upper limit deduced on this simple average basis is an adequate representation of the burst energy.

(3) The correction factor suggested here seems rather naive. First, there is no experimental evidence that the spectra of all bursts extend below 100 keV. From a comparison of the OGO and Vela results we estimate that only 60% of the events would meet this criterion[7]. Second, if the burst spectrum did, in each case, extend below 100 keV, the correction factor for the missing energy would be a function of the particular experiment. The use of a constant factor as suggested by Cline and Schmidt is absurd. The correction factor in our case was estimated to be 1.3.

(4) This point was adequately discussed in our text which we had expected to have been regarded as an integral part of our presentation.

(5) When atmospheric effects, including multiple-Compton scattering had been taken into account we estimated that the effective field of view of our detector was ~1.5π sr.

(6) The comments raised in this section have been discussed in the past in the context of cosmic-ray physics. Deductions from the mathematical treatment suggested by them is unwarranted in the absence of any established power-law index. The expression suggested by Cline and Schmidt is clearly erroneous since the value $\overline{S}/Z$ can be seen to be independent of the zenith angle for $\gamma = 3/2$. The expected number of bursts with a detector floating in the atmosphere can be written as

$$N_B = \Sigma_i\, w_i\, N(E_i)$$

where w_i is the solid angle and E_i the average threshold energy in the ith element. The expression can be solved to the required degree of accuracy with a knowledge of $N(E)$, the integral size spectrum of γ-ray bursts which is as yet unknown. Alternatively, the correction may be evaluated approximately, in a more practical way, independent of the size spectrum. For a given detector the energy deposited by a γ-ray burst must lie between E and $3E$ for zenith angles ranging between $\theta = 0$ and $\theta = 75°$. This is due to a decrease in the effective area by a cosine factor. The detection efficiency at large zenith angles, however, increases due to increased path length in Na I by sec θ. Therefore the detector can be regarded as being less sensitive by a factor of about two. Such a consideration will make our earlier results an absolute upper limit for bursts with energy greater than 5×10^{-7} erg.

We conclude that the second-order refinements discussed above can, at most, contribute a factor of about two, both in burst energy and in burst rate. Cline and Schmidt are entitled to make their own assessment of our results but we maintain that these corrections do not materially change our conclusions and that, at this stage, we see no compelling reason to reconcile our results with their hypothesis.

Beginning Model Theory

The Completeness Theorem and Some Consequences

Jane Bridge

Model theory is an important area of mathematical logic, and Gödel's Completeness Theorem and its corollary, the Compactness Theorem, form its core. These results are fundamental to understanding the relationship between mathematical theories and the mathematical structures realizing these theories. The text concentrates on first-order predicate logic and a proof of the Completeness Theorem and its main consequences, and finishes with a selective introduction to model-theoretic applications of the results. £4.50 *Oxford Logic Guides forthcoming*

Choice Sequences

A. S. Troelstra

This monograph presents a coherent and virtually complete account of the conceptual side of the theory of choice sequences. An introductory chapter is followed by an extensive discussion of the motivation and the axioms for lawless sequences, the simplest case. The formal elimination of lawless sequences and the universes that can be constructed from them by continuous operations are then treated. Finally other theories of choice sequences are detailed, as well as applications, mathematical consequences, and the connection with intuitionistic validity for the predicate calculus. £4.50 *Oxford Logic Guides forthcoming*

Pesticides and Human Welfare

Edited by D. L. Gunn and J. G. R. Stevens

This book seeks to provide objective information on the uses of pesticides in agriculture and for human and animal health, and to weigh the possible risks, and effects on the environment, against the benefits to mankind. Economic aspects, regulatory controls, and possible alternatives to pesticides are discussed. The editors have provided a survey, sponsored by a number of European chemical companies, which is both scientifically accurate and at the same time intelligible to a wide audience. Illustrated £5 paper covers £1.75

Kinetics of Chemical and Enzyme-Catalyzed Reactions

Dennis Piszkiewicz

This volume is intended to serve as a means of teaching kinetics to advanced undergraduate and graduate students. It presupposes a background in organic chemistry and some knowledge of calculus, while a familiarity with biochemistry and chemistry would be useful, though not essential. Paper covers £5.75

Irrigation Science

Editor-in-Chief: **Gerald Stanhill**, Agricultural Research Organization, The Volcani Center, Institute of Soils and Water, P.O.B. 6, Bet Dagan, Israel

Editors: **J.F. Bierhuizen**, Department of Horticulture, Agricultural University, Haagsteeg 3, Wageningen, The Netherlands; **Th.C. Hsiao**, Department of Water Science, University of California, Davis, CA 95616, USA; **M.E. Jensen**, The Director, Soil and Water Conservation Laboratory, A.R.S., U.S.D.A., Kimberly, ID 83341, USA; **St.L. Rawlins**, U.S. Salinity Laboratory, P.O.B. 672, Riverside, CA 92501, USA; **C.W. Rose**, School of Australian Environmental Studies, Griffith University, Nathan, Queensland 4111, Australia; **D. Shimshi**, Agricultural Research Organization, Regional Experiment Station, Mobile Post Negev 2, Gilat, Israel; **B. Slavik**, Czechoslovak Academy of Siences, Institute of Experimental Botany, Department of Plant Physiology, Flemingovo Nám. 2, Praha 6, Czechoslovakia

Irrigation Science will publish original contributions and short communications reporting the results of irrigation research, including relevant contributions from the plant, soil and atmospheric sciences as well as the analysis of field experimentation. Special emphasis will be given to multi-disciplinary studies dealing with the problems involved in maintaining the long term productivity of irrigated lands and in increasing the efficiency of agricultural water use.
Aspects of particular interest are:
- Physical and chemical aspects of water status and movement in the plant-soil-atmosphere system.
- Physiology of plant growth and yield response to water status.
- Plant-soil-atmosphere and water management in irrigation practice.
- Measurement, modification and control of crop water requirements.
- Salinity and alkalinity control by soil and water management.
- Ecological aspects of irrigated agriculture.

reviews

Nutrition and the developing brain

John Dobbing

Malnutrition and Intellectual Development. Edited by J. D. Lloyd-Still. Pp. 194. (MTP: Lancaster, 1976.) £8.95.

A SMALL epidemic of recent books on or around this topic imposes a special need to justify the addition of any new one to the bookshelves. Dr Lloyd-Still's is an edited volume of six reviews or essays, dealing in turn with: effects of undernutrition on the growth of the physical brain and on "mental competence"; techniques of psychological testing in this context; some studies of the subsequent physical and intellectual development of children inevitably malnourished in the course of certain clinical conditions in affluent society compared with eleven major studies from the underprivileged world; and finally the "social ecology" of malnutrition in childhood. It is nicely produced, and there is certainly enough excellence to justify its place alongside other recent books (for review, see *Nature*, **262**, 521, 1976).

After a very thoughtful introductory chapter by the editor in which he gives a very balanced description of the whole subject, there is a disappointing second chapter by Peter Chase on the physical effects of undernutrition on the growing brain. I think my dissatisfaction with it largely derives from Chase's total lack of humility before the amazing complexity of the developing brain. Where the rest of us use curves of brain weight, cell number, myelin lipid and so forth as crude indicators of the timing of developmental events so as to identify hypothesised periods of enhanced vulnerability. Chase seems to think of such parameters as of specific significance in themselves. They are, of course, merely the things we can conveniently measure. Some of his graphs of their accumulation in whole brain are misleadingly wrong in places. And who is interested in whole brain quantities anyway, except in the limited sense mentioned above?

The third chapter by epidemiologists Zena Stein and Mervyn Susser draws heavily on their fascinating study of the effects on fetal growth and 19-yr-old achievement following the Dutch wartime famine during the winter of 1944–45. This is a beautifully written, distilled account of their findings, cleverly described in the setting of many other epidemiological studies, including some in which there is experimental nutritional intervention. The book deserves to be bought for this chapter alone.

The Hurwitz chapter on psychological testing in studies of malnutrition is very useful in a different way. Assuming his descriptions of the test methodology are reliable (and I cannot judge that), I was most impressed with his account of the limitations of such tests in the present context. The problems of cross-cultural validity together with the difficulties of drawing "growth-curves" against age in longitudinal studies, seem even more formidable than one had imagined, to say nothing of the hazards in using infant tests as predictors of long term performance.

Lloyd-Still returns in Chapter 6 to discuss "Clinical Studies", by which he means direct studies on children. His tabulated condensation of 13 major studies includes 11 of socioeconomic or cultural malnutrition and two in which malnutrition was secondary to clinical conditions in our own privileged communities. The breadth of his discussion is impressive and partly derives from his conspicuously profound experience as a children's doctor. One day, however, we shall have to abandon discussion of some of the earliest field studies since it is now too easy and somewhat redundant to criticise them. Their place is in historical introductions to theses.

The last chapter on the social ecology of childhood malnutrition unfortunately returns to the rather lower standard of the second. It may well be true that the "Soviet Union, which was able to purchase . . . grain with devalued dollars at prices subsidised by the United States Government, realised further profit, both economic and political, by selling, lending and granting of American grain to other countries"; but such statements are below the generally very high standards of objectivity in the remainder of this book. □

John Dobbing is Professor of Child Growth and Development in the Department of Child Health at the University of Manchester, UK.

Electrons in liquid ammonia

Electrons in Liquid Ammonia. By J. C. Thompson. Pp. xii+297. (Clarendon: Oxford; Oxford University: London, 1976.) £14.50.

THIS book is a gold mine of information for anyone working in any area of electrons in fluids. It is written by a person who has contributed to all of the many areas represented in this monograph. Professor Thompson has not only collected all of the major experimental and theoretical work on the subject but has presented it in a very critical but very fair manner. After reading this book everyone should have a better feeling for our present state of understanding as well as the remaining problems.

The major topics include "metal–ammonia solutions as liquid metals", "metal–ammonia solutions as electrolytes", "the metal–nonmetal transition", "liquid–liquid phase separations", "solutions of alkaline earth and rare Earth metals", "solid metal–ammonia compounds", and "solutions in other solvents". Each chapter contains material which will prove useful to even the most well informed reader on the present status of each topic. The presentations are remarkably up to date and inclusive.

The strongest single point of this book is its emphasis on those areas in which our understanding of experimental data is very incomplete. In this regard one might mention spin pairing and the "metal–nonmetal" or conductivity transition. In these cases the author has made a special effort to quote all of the essential experimental facts as well as to make the stongest possible case for all of the alternative theoretical models (pointing out in addition that all fail on some other points).

This book is so vital that any researcher in any related field would be negligent if this book were not actively used as part of his routine research. **Neil R. Kestner**

Neil R. Kestner is Professor of Chemistry at Louisiana State University, Baton Rouge, Louisiana.

Human immunology

Immunology of Human Reproduction. Edited by J. S. Scott and W. R. Jones. Pp. xviii+476. (Academic: London; Grune and Stratton: New York, 1976.) £15.

THIS is a fascinating book for all those who have an interest in immunology and development. The book begins with a glossary and a primer of immunology that has freed later chapters from the need to define and explain. This introductory section is oversimplified in places and occasionally patronising, but these faults are outweighed by the good it does in summarising and ordering a field overgrown with observations and special terminology.

Although no formal break is made, I would divide the remaining chapters into two sections: chapters 2–6 dealing with basic aspects of immunology in development, and drawing on both clinical material and animal, model, experiments; and chapters 7–13, dealing largely with clinical aspects of human immunology and development. The chapters are of varied length, quality and distance from the stated topic of the book, but they all elaborate their topics in considerable detail, and it is this detail that is the book's strength.

The authors themselves are often moved by the complexities and uncertainties of the topics, to use phrases like "the tip of the iceberg of confusion" or to make statements such as "existing knowledge concerning the role of immunological factors in gestosis is fragmentary . . ." or "the picture . . . as in so many areas of reproductive immunology is confused . . ." This confusion is, however, the result of contradictory or insufficient clinical and experimental observations, and by detailing these the authors have done a great service, allowing others to speculate on, and experiment over, the data presented here.

The fields of immunology and reproduction are connected at many points. Chapter 2, by M. H. Johnson, makes a connection between the two by discussing the stages of early mammalian development (exemplified by the mouse embryo) and some ways in which immunological techniques may be used to characterise these stages. In this chapter the problem is raised of the maternal immune response to antigens of the embryo, either to alloantigens, or to stage-specific antigens. This problem, still unsolved, is reiterated in later chapters, notably that by Billington on the immunology of trophoblast, and in a chapter by Medenhall, which considers all aspects of maternal–foetal immunology, transfers of maternal immunoglobulins and cells, and the problem of the foetal allograft. A further comment on the problem is made by Gusdon, in a chapter on the effects of pregnancy on all maternal immune responses. The first section closes with a chapter by W. Jones on the phylogeny and ontogeny of the immune response. This chapter considers development of foetal immune responses in its own right. It is perhaps too broad and contains a few notable factual errors (the mouse is assigned a 30-d, not a 20-d gestation period), but the section on the maturation of the immune responses of the human foetus is thorough, including the immunological aspects of breast feeding, and quite interesting.

In the second section we are given extended treatments of particular topics. Some, such as that of chapter 7 on the consequences of maternal infection for the foetus, cut across the divisions set up in the earlier chapters. Others, such as a chapter on the effect of pregnancy on immunological diseases of the mother, analyse a limited topic within the larger one already set. Maternal–foetal immunological interactions are prominent in Rh disease, and this topic receives full treatment in a chapter which emphasises clinical aspects of the disease, although failing to discuss the molecular aspects of Rh antigens and of the transfer of Rh antibodies across the placenta. Gestosis (eclampsia/preclampsia), a condition involving the immune response in some obscure manner is also given a chapter of its own. If we are not convinced at the end of this chapter that the condition is due to immune responses, neither are we put off further exploration of the problem. Similarly, the role of the immune system and of cell surface antigens is unclear in cases of trophoblastic neoplasms. Again, the question cannot be answered but it is well set out and elaborated. Other chapters cover non-gestational reproductive tract neoplasms, and immunological aspects of infertility as well as the prospects for immunology in the control of fertility. All of the chapters carry long lists of references: the average is about 130; and one chapter, that by Edwards on immunology and fertility control contains 390.

The immunology of reproduction is a vast subject and, as will be seen from the individual subjects mentioned, may be taken in many senses. It would be too much to expect a consistent exposition of the subject; indeed, such an exposition would certainly be highly biased, if not false. The opposite approach taken here, if it occasionally daunts the authors, stimulates their readers.

Michael Edidin

Michael Edidin is Professor of Biology at Johns Hopkins University, Baltimore, Maryland.

Volcanic picture book

Volcanoes and Impact Craters on the Moon and Mars. Pp. 463. By P. Leonardi. (Elsevier Scientific: Amsterdam and NewYork, 1976.) Dfl.166; $59.75.

AT a first glance this book is very impressive; it is beautifully presented and contains large numbers of high quality pictures, both in colour and in black-and-white. For a subject which relies much on interpretation of photographs taken of other planets, this is highly commendable. The author has not only reproduced the standard NASA and Soviet pictures taken from spacecraft but has also included many extremely interesting pictures of geological phenomena on Earth.

Although the book was originally written in Italian it has generally speaking been well translated into English and reads easily. The author has obviously read widely around this subject and there can be few planetary scientists who will be disappointed at not finding their name in the index.

In view of these comments the reviewer would have liked to have recommended this book. But although pictorially the book is very much up-to-date (even containing Viking pictures), many of the ideas expressed in the text are reiterations of ideas current among some scientists in this field more than ten years ago, before spacecraft exploration of the Moon and planets. Much of the book is devoted to the old argument of impact as against volcanic craters on the Moon, and although the author presents the 'impactists' case fairly, his conclusions lie well within the 'volcanic' camp and would not be accepted by most planetary workers who have studied the evidence obtained during the past ten years.

Sadly, although recommended for its presentation and picture quality, this book will be of little interest to scientists in the field and can only be recommended to students for the historical interest of the text.

J. E. Guest is Lecturer in the Department of Physics and Astronomy at University College, London, UK.

Membrane enzymes

The Enzymes of Biological Membranes. Vol. 1: Physical and Chemical Techniques. Pp. xiii+257. £10.50; $20. Vol. 2: Biosynthesis of Cell Components. Pp. xvii+654. £28; $55. Vol. 3: Membrane Transport. Pp. xv+459. £21; $39. Vol. 4: Electron Transport Systems and Receptors. Pp. xv+431. £20; $37. Edited by A. Martonosi. (Wiley: London, 1976.) (US edition published by Plenum: New York, at slightly different prices.)

THESE volumes form the first four of a series which sets out to collect together and evaluate information on membrane enzymes. Most of the information is concerned with the relationship of enzymes to their membrane, and with their involvement in membrane phenomena. Very detailed information on the structure of each enzyme is usually lacking, since the purification and structural analyses of most membrane enzymes have not advanced as far as for their soluble counterparts.

Some membrane enzymes are dealt with singly, others appear as part of enzyme systems. It is clear from the volume titles that the word 'enzyme' has been interpreted very loosely. Thus, in addition to proteins with clear enzymic activity, the coverage includes binding proteins of various persuasions, transport components without enzymic activity, and light-trapping systems; in short, membrane proteins with clearly documented biological function. This is a reasonable extension in the context of an attempt to provide an insight as to how membranes function. Very few important 'enzymes' have been omitted.

Each volume is a multi-author effort; the cast-list is impressive and most authors do their subject (and themselves) justice. The coverage given to different 'enzymes' varies; in some cases this is an overall view of the 'enzyme' and its relationship to the membrane, whereas in other chapters the emphasis is more firmly on recent developments. On the whole, most contributors reflect the state of knowledge in each field but occasionally reveal a personal bias which may limit the usefulness of their chapter.

In the first volume the uses of various techniques are discussed in establishing the general fluidity of the membrane lipid layer, in demonstrating a collar of lipid around the inserted portions of some proteins, and in interpreting the response of some enzymatic activities to temperature change; all of these discussions use suitable examples. Much of the same work is, however, discussed again in other volumes in relation to the properties of the individual enzymes used as the examples in volume 1. This excessive overlap could have been avoided, as could the length of those contributions taking over 30 pages to discuss a single 'enzyme'.

Volume 4 is a very artificial assembly; the few chapters on receptors, with the exception of that on rhodopsin, have little in common with those on electron transport systems. The receptor chapters would have been better separated off into a further small volume or would have associated better with the transport components. Such considerations are clearly of importance to purchasers of individual volumes but of less importance when considering purchase of the series for a library.

To have such a convenient and comprehensive source of material on membrane enzymes will be a considerable asset in both teaching and research. The series is clearly one for library purchase since it is too comprehensive and expensive for individual subscription. Each volume deals with a coherent group of topics (with the artificial addition of the receptor section to volume 4); although expensive, they are therefore more attractive for single volume purchase than many serial publications.

Roger Coleman

Roger Coleman is Senior Lecturer in the Department of Biochemistry, at the University of Birmingham, UK.

Disease resistance in plants

Defence Mechanisms of Plants. By B. J. Deverall. Pp. 110. (Cambridge University: Cambridge, London and New York, 1977.) £5.50.

THROUGHOUT their lives plants are exposed to infection by many parasitic microorganisms. Yet infection often fails and the plants remain healthy. Professor Deverall's excellent book is concerned with the processes by which plants perceive the parasite, and occasionally permit but usually discourage its further progress.

Professor Deverall does not attempt an extensive account of the subject but rather chooses to present a selective personal view of recent research pertaining to the processes of resistance to disease. Emphasis is placed on events which occur after a plant has been infected and covers cytological changes, the production of antimicrobial compounds (phytoalexins), induced resistance and the mediation of host–parasite specificity. Each chapter contains a summary of the facts, which is well supported by reference to original and review papers, an assessment of their significance or otherwise, an indication of the problems remaining, and in some cases how they may be solved. Few significant errors or omissions have been noticed although the promise to expand the concept of infection type to all host–parasite interactions is rarely fulfilled.

This book is extremely timely in that it appears alongside several other publications, which although containing more detailed information often fail to analyse it critically. In this respect, Deverall, rather than merely providing a list of phytoalexins, presents a welcome evaluation of the evidence for their rôle in resistance and the mechanisms of their induction. The close association between cell death and phytoalexin synthesis rightly receives much emphasis, but his conclusion that phytoalexins are synthesised in living cells may be somewhat premature.

Professor Deverall states that he envisages his readers to be research workers and university lecturers, and their advanced students. The book can be recommended as essential reading for such people. It will convey the progress achieved by and the challenges remaining for physiological plant pathologists.

Atmospheric chemistry

Atmospheric Chemistry. By J. Heicklen. Pp. xiv+406. (Academic: New York and London, 1976.) $38; £27.

In view of the rapid expansion in knowledge of the chemistry of the Earth's atmosphere in recent years, publication of a new volume on this topic is timely. *Atmospheric Chemistry* by Julian Heicklen, however, does not in any way achieve the standard of information collection, dissemination and presentation in the two notable publications on this topic in the early 1960s: Leighton's *Photochemistry of Air Pollution* and Junge's *Air Chemistry and Radioactivity*.

The reason for this failure mainly arises from the authors attempt to cover too much ground; indeed some of the topics discussed—such as the kinetics and mechanism of hydrocarbon combustion, the detailed effects of urban pollutants on plants and animals, and pollution control methods—are inappropriate to the field encompassed by the title. On the other hand there is inadequate coverage of the basic large-scale and local meteorological factors determining the transport mechanisms that are so important in defining the reactor in which the chemical reactions take place.

In addition, the overall emphasis is very much towards photochemistry. Although it is true that the absorption of solar radiation is the primary driving force for chemical reaction in the atmosphere, the chemical interactions of trace gases with precipitation elements and the wash-out and rain out processes have an important part to play in the overall atmospheric cycles, and these are hardly discussed at all. This lack of balance detracts from the overall usefulness of the work in presenting an overview of the science of atmospheric chemistry.

The author must be credited, however, with the collection of a large amount of photochemical and kinetic information on the chemical reactions which may occur in the atmosphere. In the chapters on chemistry of the upper atmosphere and on photochemical smog, simple model calculations are developed to demonstrate how the trace gas composition in each particular atmospheric region can be simulated using the chemical kinetic information. This is basically a useful presentation, but unfortunately the arguments tend to become too complex and difficult to follow. Also, the uncertainties in applying the results to real atmospheric situations are not emphasised. For example, in the discussion of a model photochemical smog system, the reader is left with the impression that ozone concentration in sunlit exhaust-polluted atmospheres are governed solely by the photochemical reactions. The important and often dominant role of meteorology, in determining ozone concentrations is not mentioned.

The lack of emphasis on precipitation chemistry is very apparent in the chapter dealing with SO_2 chemistry. A comprehensive 10-page summary is given of laboratory data on SO_2 photochemistry, a process which is widely accepted as being of negligible importance in the atmospheric chemistry of SO_2. The droplet-phase oxidation of SO_2 is, on the other hand, dealt with in a cursory fashion with no reference to some of the early classic work carried out on this important system.

In addition to the above mentioned chapters, there is a concise description of the chemistry of the ionosphere, a long chapter on atmospheric pollutants, which contains very little atmospheric chemistry and a lot of useless information on concentrations in US cities and deleterious effects, together with a short but not very illuminating chapter on aerosol chemistry. A chapter entitled reactions of O_3 and singlet O_2 also contains a detailed discussion of NO_2 photolysis.

There are some misconceptions and inaccuracies which are unsatisfactory for a book of this kind. For example, it is stated that "The troposphere is a relatively quiescent region (of the atmosphere) where relatively little chemistry occurs . . . The global atmosphere chemical cycles can be summarised as mainly oxidation occurring in the stratosphere . . .". This statement is manifestly untrue. In fact, nearly all of the gaseous material emitted into the atmosphere from the Earth's surface fails to penetrate the tropopause. It is oxidised or otherwise scavenged in the troposphere where 80% of the atmospheric mass resides.

Ion cyclotron resonance spectrometry

Ion Cyclotron Resonance Spectrometry. By T. A. Lehman and M. M. Bursey. Pp. xi+230. (Wiley-Interscience: New York and London, 1976.) £15.95; $27.30.

Ion cyclotron resonance (ICR) spectrometry has been widely used during the past 10 years for the study of the chemistry of ions in the gas phase. Although it has found many applications in the field of chemical physics, it has been used increasingly in studies of the structure and reactivity of organic ions and in the elucidation of reaction mechanisms which parallel those observed in solution. It is on the latter group of applications that this volume concentrates, and by far the longest chapter in the book is devoted to a discussion of such topics as gas-phase acids and bases, nucleophilic and electrophilic substitution reactions, and structures of ions. It is written from the viewpoint of a physical/organic chemist and a number of interesting comparisons are drawn with results obtained from studies of solution kinetics.

This illustrates one of the major problems in writing a book on a particular experimental technique: the subject of gas-phase ion chemistry is much bigger than ICR spectrometry and by confining themselves largely to examples based on ICR studies, it can be argued that the authors present an incomplete and selective view of the field. For example, results obtained from high pressure mass spectrometry or by flowing afterglow and flowing after-drift methods have proved of considerable interest; and although comparisons are drawn between these results and those obtained by ICR spectrometry, discussionof them is necessarily brief.

The first two chapters of the book provide a very readable introduction to the technique in which the reader is encouraged to explore the possibilities of the technique without worrying too much about the finer points of its theory of operation. The chapter on reaction mechanisms is followed by a discussion of theoretical aspects of power absorption, linewidths and extraction of rate data together with a brief review of current theories of ion molecule reactions at near thermal energies. The final chapter briefly describes various applications of ICR spectrometry in the field of chemical physics. The book concludes with an extensive bibliography and two appendices.

The book provides a useful introduction to ICR spectrometry and to physical/organic aspects of gas-phase ion chemistry but the chemical physicist will find little which is not adequately covered in review articles. The problem with any book on a particular technique is that it is necessarily limited in its scope; and although the reader will know quite a lot about ICR spectrometry, if he gets through this book, he will not be in a position to assess its advantages and disadvantages relative to other techniques used in the study of gas-phase ions.

obituary

Sir Gerard Thornton

MICROBIOLOGISTS, especially those who had the good fortune to work with him, will have heard with sadness of the death of Sir Gerard Thornton on 6 February at his home in St. Albans at the age of 85. He is survived by his widow, Gerda, who is Danish, and by his son Peter who is Keeper of Woodwork and Furniture at the Victoria and Albert Museum.

He will be remembered for his many original and important studies on soil microbes, made in the course of a long career spent almost wholly at Rothamsted Experimental Station, Harpenden. He was educated at Radley and at New College Oxford and joined Rothamsted shortly after the end of the Great War where he had served as a pilot in the Royal Flying Corps.

In 1919, soil microbiology was a very rudimentary science, and Thornton's early work was much concerned with the devising of techniques for isolating, identifying and counting various kinds of soil bacteria and in promoting parallel studies by others on soil fungi, protozoa and other groups. With his friend the late R. A. Fisher he pioneered the application of statistics to the problems of enumerating bacteria in soil. At this time he was also in contact with the great European soil microbiologists—Beijerinck, Winogradsky, Kluyver and later with Waksman. He had a special interest in the microbial breakdown of aromatic disinfectants in soil, and made a collection of bacteria able to utilise cresols, phenols and naphthalene as sole carbon sources and elucidated some aspects of their physiology. This work was later to become specially relevant to the discovery, which he shared with others, of the selective hormone herbicides (chlorinated phenoxyacids), first published in *Nature* (**155**, 498; 1945).

His greatest influence, however, was through his distinguished research on biological nitrogen fixation, especially by root-nodulated leguminous plants. His detailed investigation of their microbiology, structure and physiology laid the foundation for nearly all later work and led to practical applications in UK agriculture. His work established the 'bacteroid' as the nitrogen fixing site in the nodule and he described in detail the features of ineffective, non-fixing nodules. With his Rothamsted colleagues he was the first to use serological methods for identifying rhizobia and was associated with early work on bacteriophage and with studies on ecology of rhizobia. Thornton was also the first to investigate effects of competition between strains in the soil, a matter later shown to be important in the development of efficient 'inoculants' for leguminous crops. Since his retirement in 1957 he continued to show the greatest interest in nitrogen fixation and in the striking advances made world-wide in its study during the last decade, stimulated by the International Biological Programme and the energy crisis.

Thornton had wide interests in science and in the arts. He was especially interested in archaeology and in palaeontology and had the distinction of discovering a new species of plesiosaur (*Rhomaleosaurus thorntonii*) which can be seen at the British Museum, Natural History.

Thornton became head of the Department of Soil Microbiology in 1940. He was elected to the Fellowship of the Royal Society in 1941, of which he was Foreign Secretary from 1955–60 and a Vice-President in 1959–60. He was actively involved in the organisation of the Society's Tercentenary celebrations and was knighted in 1960. He served on the Council of the Royal Society and on many bodies concerned with microbiology and with agriculture.

Thornton was a quiet, modest man, invariably considerate and courteous with a charm of manner rarely seen today. His colleagues remember him with respect and affection.

P. S. Nutman

D. E. Wheeler

DR D. E. WHEELER who died on January 24, was a chemist who in twelve years as Managing Director of The Wellcome Foundation, Limited and a further three as a Deputy Chairman was concerned particularly with the profitable translation, through development and production, of the fruits of scientific research into important drugs and vaccines. As President of the Association of the British Pharmaceutical Industry he was a leading figure during an era when regulations were being established in the wake of the thalidomide tragedy. His integrity, relied upon alike by those in industry, medicine and government, was a major factor in the harmonious and successful negotiations. As first-ever Chairman of the Spastics Society he brought together two organisations concerned with the welfare of spastics and presided over a massive expansion on the financial side, making possible the sponsorship of original research on a considerable scale.

Denis Wheeler was born in Bristol on 6 September, 1910, and graduated from Bristol University where he specialised in physical chemistry and carried out research work which led to a Ph.D. in 1934. He was awarded a Salters' Fellowship to study industrial organisation and practice in the United States. Part of the time was spent at Princeton University where he studied advanced physical chemistry. In later years he was to become Master of the Salters' Company and concerned with the continuation of this type of scientific exchange.

On his return to Britain he joined the research department of Imperial Chemical Industries (Explosives) Ltd where he eventually became technically responsible for all acid production throughout the ICI organisation in Great Britain. In 1940 he was appointed research and development director of Hardman and Holden Ltd, chemical manufacturers.

He joined the board of directors of The Wellcome Foundation Limited in January 1946, was appointed assistant managing director later that year, joint managing director in 1948, managing director in 1955 and a deputy chairman in 1967. He retired from the board for health reasons in 1970. He was awarded the CBE in 1965.

In his early years with the Wellcome Foundation, Dr Wheeler was concerned with the organisation of development as a specific function, ensuring that the discoveries of the research laboratories could be produced in the appropriate formulations and on a sufficient scale to be administered to large numbers of humans or animals throughout the world. Whereas the research laboratories of Wellcome had been largely independent of the commercial company, he was able to convince the scientists that their work could still retain its integrity and its impetus whilst being guided towards the discovery of essential medicines, the sale of which would provide the resources for further research.

D. W. Adamson

announcements

Appointment

Brian J. Brinkworth, to the newly created Chair of Energy Studies at University College, Cardiff.

Meetings

4–6 May, **3rd International Congress on Ozone Technology,** Paris (International Ozone Institute, 52 rue d'Anjou, 75384 CEDEX 08, Paris).

8–12 May, **8th International Congress of the International Society of Psychoneuroendocrinology,** Atlanta, Georgia (R. P. Michael, Psychiatry, Emory University School of Medicine, Atlanta, Georgia 30322).

9–11 May, **Beltsville Symposium II: Biosystematics in Agriculture,** Beltsville (J. A. Duke, Plant Taxonomy, Room 117, Bldg 001 BARC West, USDA, Beltsville, Maryland 20705).

10 May, **Protein Production: Problems for the Agricultural Engineer,** London (E. Holden, The Institution of Agricultural Engineers, Silsoe, Bedford, UK).

17–21 May, **The Study of Macromolecules by NMR,** Grasmere (The Chemical Society, Burlington House, Piccadilly, London SW1).

18 May, **Opto-Electronics for Measurement and Control,** London (The Institute of Physics, 47 Belgrave Square, London SW1).

18 May, **Animal Health Products—Design and Evaluation,** Groton, Connecticut (D. C. Monkhouse, Pfizer Central Research, Groton, Connecticut 06340).

19–21 May, **The Evolution of Galaxies and Stellar Populations,** Yale (B. M. Tinsley, Yale University Observatory, Box 2023 Yale Station, New Haven, Connecticut 06520).

23–27 May, **2nd European Conference on Marine Technology–Safety at Sea,** London (WEMT 77, 10 Upper Belgrave Street, London SW1).

30 May–3 June, **Ferritic Steels for Fast Reactor Steam Generators,** London (British Nuclear Energy Society, The Institution of Civil Engineers, 1–7 Great George Street, London SW1).

1–3 June, **Environmental Pollutants—Animal Models and Wildlife as Monitors,** Connecticut (G. Migaki, Armed Forces Institute of Pathology, Washington, D.C. 20306).

1–3 June, **31st Annual Frequency Control Symposium,** Atlantic City (J. R. Vig, Fort Monmouth, New Jersey 07703).

7–9 June, **11th Annual Conference on Trace Substances in Environmental Health,** Columbia (D. D. Hemphill, 411 Clark Hall, University of Missouri, Columbia, Columbia Missouri 65201).

Person to Person

A new bivalve mollusc is spreading in the North Adriatic sea; it is similar to *Anadara* or *Scapharca* species except for its greater size (up to 8 cm). Each animal possesses several ml of haemoglobin rich blood. I would be grateful for any information on this topic. Photographs of the mollusc are available on request. Please write to Dr Silvio Buzzi, Felisatti 49, 48100, Ravenna, Italy.

Exchange furnished family house near Littlehampton, West Sussex for similar in Canberra, August 1977–July 1978. Pleasant neighbourhood, near shops, schools, and sea. Brighton 40 min, London 90 min. Exchange of car (Renault 4) also considered. Contact John Thornley, 5 Harsfold Road, Rustington, Littlehampton, West Sussex, UK.

There will be no charge for this service. Send items (not more than 60 words) to Marcus Dobbs at the London office. The section will include exchanges of accommodation, personal announcements and scientific queries. We reserve the right to decline material submitted. No commercial transactions.

7–9 June, **Deburring and Surface Finishing,** Chicago (Society of Manufacturing Engineers, 20501 Ford Road, Box 930, Dearborn, Michigan 48128).

18–19 June, **International Symposium on Gut Hormones,** Lausanne (S. R. Bloom, Medicine, Hammersmith Hospital, Du Cane Road, London).

19–25 June, **Inborn Error of Metabolism in Man,** Tel Aviv (O. Sperling, P.O. Box 16271, Tel Aviv, Israel).

20–25 June, **6th International Congress of Lymphology, Prague** (Secretariat: Sokolská 31, 120 26 Praha 2, Czechoslovakia).

20–22 June, **4th International Symposium on Mass Spectrometry in Biochemistry and Medicine,** Lake of Garda, Italy (A. Frigerio, Instituto di Ricerche Farmacologiche 'Mario Negri', Via Eritrea, 62-20157 Milan, Italy).

27–30 June, **Annual Meeting of the Genetics Society of Canada,** Manitoba (P. J. McAlpine, Genetics, Health Sciences Childrens' Center, 685 Bannatyne Avenue, Winnipeg, Manitoba, Canada).

27 June–1 July, **7th International Conference on Amorphous and Liquid Semiconductors,** Edinburgh (Secretariat, Centre for Industrial Consultancy and Liaison, 14 George Square, Edinburgh).

3–8 July, **3rd International Congress of Immunology,** Sydney (Secretary, P.O. Box 391, Darlinghurst, NSW 2010, Australia).

4–8 July, **Rhythmic Activity of Fish,** Stirling (J. E. Thorpe, Freshwater Fisheries Laboratory, Pitlochry, Perthshire, Scotland).

6–8 July, **Hot Electrons in Semiconductors,** Denton, Texas (D. G. Seiler, Physics, North State Texas University, Denton, Texas 76203).

11–14 July, **5th International Symposium on Gas Kinetics,** Manchester (UMIST, P.O. Box 88, Manchester, UK).

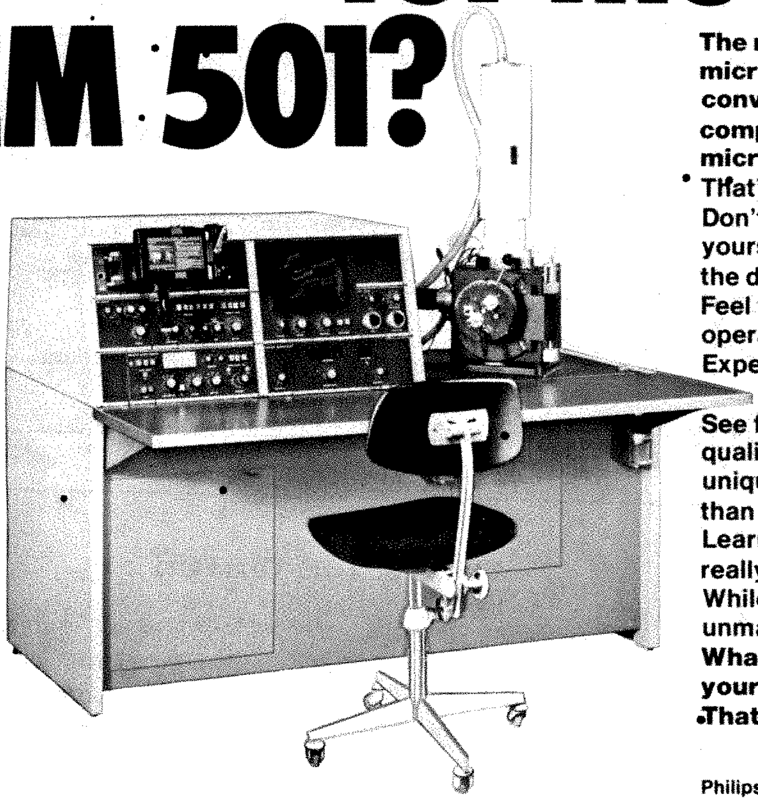
11–14 July, **International Symposium on Dendrochronology,** London (Organising Secretary, National Maritime Museum, London).

11–15 July, **8th International Conference of the World Association for the Advancement of Veterinary Parasitology,** Sydney (Secretary, CSIRO McMaster Laboratory, P.M.B. No. 1, Post Office, Glebe, NSW 2037, Australia).

11–15 July, **2nd International Conference on The Organometalic and Coordination Chemistry of Germanium, Tin and Lead,** Nottingham (P. G. Harrison, Chemistry, University of Nottingham, Nottingham).

17–22 July, **International Symposium on Macromolecules,** Dublin (Macro Dublin 77, Institute for Industrial Research and Standards, Ballymun Road, Dublin 9, Ireland).

Why believe all our claims for the new SEM 501?



The new SEM 501 gives you better micrographs, consistently, more conveniently than with any other competitive scanning electron microscope.
That's our claim.
Don't believe it until you prove it for yourself. Bring your own samples. Sit in the driver's seat of our SEM 501.
Feel for yourself how convenient it is to operate.
Experience for yourself the benefits of a built-in eucentric goniometer.
See for yourself the uncompromised quality you get from the videoscope and unique greyscale generator. . . and better than 70 Å resolution time after time.
Learn for yourself what SEM versatility really means!
While you're here, learn about our unmatched total support service.
What you see in our lab you'll get in your lab.
That you can believe!

Philips Industries, Electron Optics Department,
Building TQ III-2 Eindhoven, The Netherlands.

Just sit in this driver's seat!

Seeing is believing!

☐ I'd like to sit in the driver's seat of your new SEM 501 Please contact me for a personal demonstration.
☐ For the time being, full documentation will do.
☐ Put me on your mailing list for technical/application bulletins.

Nature

for your reference.

Index

The index to 1976 issues of *Nature* is now available. The index assists quick, easy reference to past issues by listing papers both by author and subject.

Price (post-paid): UK £2.50; Rest of world US $5.00.

Binders

Keep your copies of *Nature* protected in specially designed black PVC binders. Four of these durable binders will hold a year's copies of *Nature*. They have a clear pocket on the spine for insertion of your own references.

Price (post-paid): UK £2.50 each or four for £8.00; Rest of world US $5.00, four for US $16.00.

Orders with correct remittance should be sent to:

Nature, Circulation Department,
Macmillan Journals Ltd,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England.

Scientists think, too

IMAGES of science and the scientist and of engineering and the engineer are much discussed at present. The most recent issue of *Physics Today* contains W. A. Fowler's Presidential Address to the American Physical Society in which some ideas on brushing up the physicist's image are put forward. British engineers, deeply concerned at what they believe is society's lowly rating of them, have been puzzling for some time over how they can better present their profession. And the Spring issue of *Science for People*, the magazine of the British Society for Social Responsibility in Science, is devoted to images of science; we are told that scientific work, being subject to an extreme division of labour, 'tends to be boring, unfulfilling, alienating and unhealthy like most jobs in a capitalist society . . . Being a scientific worker means working in a patriarchal, repressive hierarchy, often in bad working conditions, without control over the fruits of one's labour'.

Images are, of course, needed for a variety of purposes. The student will see the scientific profession in a certain light and will accordingly decide whether or not to contemplate a scientific career. The industrial employer will have a different sort of perception of science related to value to the company. The politician will want to know whether scientists and technologists are basically trustworthy in their advice or whether they are prone to empire building and self-serving pronouncements. The layman, relying more and more on science and technology to deliver the goods, will have his or her own view of whether the scientist and technologist substantiate their claims. Occasionally in all of these directions we can be pleasantly surprised at the reservoir of goodwill, trust and interest which remains.

But there is one image which is in danger of being submerged amidst the recent frenzy to project science as still valuable and scientists as (in Fowler's words) capable, practical, ingenious, innovative and at the same time human beings. That is the image of scientists as thinkers. The public still remembers Einstein and recognises him as a great thinker, but is science in general considered to be a thinking profession? Of course this image is not necessarily one which will be for mass-consumption, but it is an important one nevertheless, because other people in our society most certainly regard themselves as thinkers and it is important that they do not dismiss scientists as doers only, and therefore of not being capable of participating in sensible general discussions on broad matters of policy. This has happened to a large extent in Britain already, with precious little action from bodies which are supposed to have the scientist's interest at heart. There is deplorably little involvement of the scientist in what migh be called 'the life of the nation' and the process is, of course, self-reinforcing: the more the exclusion, the smaller the number of those who can talk sense.

What to do to establish toeholds? Clearly anything involving the expenditure of large sums is not going to be feasible in the near future, so we may have to rule out such desirable ideas as seconding scientists to work with politicians, or the establishment of new interdisciplinary institutions. There still remain, however, opportunities within the media—the arch-purveyors of image. Last year there was great satisfaction that a young biologist should be asked to deliver the BBC's Reith Lectures. But very few scientists are allowed to express their own views in any extended way either on work they are involved in themselves or on more general matters. The formula is generally that scientists, if allowed to speak or write at all for the general public, do so almost invariably through short extracts only, with a journalist or reporter on hand to explain what the scientist means. There is nothing fundamentally wrong with this format (not that many professors in the humanities would stand for it), but in the absence of more extended contributions in the columns of serious newspapers, in magazines and in radio talks, the impression is undoubtedly left that scientists aren't really capable of stringing together more than a few dozen words, are only worth hearing on their very narrow speciality and are best not disturbed in their busy life of doing things. It is time the thinking side of science was given a more public airing. □

Chemical disarmament still elusive

THE Spring session of the United Nations Conference of the Committee on Disarmament (CCD) droned to a close in Geneva this month with little concrete progress made on the thorny issues involved in negotiating a chemical disarmament treaty. Though a proposal put forward last year by the British delegation received many general endorsements—including one from the United States—delegates have been marking time for the past three years awaiting a long-promised but elusive joint proposal from the United States and the Soviet Union.

Part of the problem stems from the fact that there is considerable confusion about the United States position, particularly in regard to the US Army's plans to launch a massive new programme to replace its existing chemical weapons stockpiles with so-called binary chemical weapons. The time has come for President Carter to clarify the matter.

The background is this. In the early 1970s, while US delegates were telling the CCD that the United States supports chemical disarmament, the US Army was requesting funds from Congress to begin building binary weapons—nerve agents made from two non-lethal components which form a deadly compound when mixed together. Not surprisingly, the negotiators were not taken very seriously. In 1974, however, Congress refused to appropriate the funds. Undeterred, the Army came back with another request the following year. This time, the House Armed Services Committee deleted the funds, but it stated that unless progress is made at the CCD talks, future requests for binary weapons would be viewed more favourably.

Consequently, no funds were requested for binaries in the budget proposed by President Ford early last year, but the Army nevertheless argued within the Administration for the programme to be reinstated in President Ford's final budget, presented to Congress last January. Ford decided not to include the funds, however, and passed the matter on to his successor. The binary programme is therefore far fom being killed off, and it still looms large over the CCD talks.

While this was going on, President Nixon and Secretary Brezhnev announced at their summit meeting in July 1974 that the United States and the Soviet Union would offer a joint initiative to break the deadlock at the CCD talks. So far, however, only two rounds of bilateral discussions have been held, the last of which took place early in April, and little progress was made.

Very tricky issues concerned with measures to police a chemical disarmament treaty are involved in the negotiations. But the time has come at least for President Carter to clear the air by announcing that the United States will scrap its plans to produce binary weapons and that the new Administration is serious about chemical disarmament.

The microprocessor phenomenon

Basil Zacharov separates fact and fiction to comment on the microprocessor 'revolution'

SINCE the introduction of the first commercial microprocessor in 1971 by INTEL the growth in number of microprocessors has been little short of phenomenal. It is estimated that the present sales, already £10 million for the European market, will grow at least tenfold by 1980. Microprocessors are used in scientific, domestic, military and commercial applications. Conferences entirely devoted to microprocessors are now commonplace. There are professional journals which are concerned only with microprocessors. And there is hardly any research grant application with a computing or electronic content where the word 'microprocessor' does not appear somewhere or other.

The microprocessor is an electronic device, fabricated on a single small semiconductor chip, enabling certain operations to be performed on input digital data, the transformed data then becoming available either on an output data highway, or in appropriate internal registers of the microprocessor. Depending upon the choice of microprocessor, the width of the data path may be anything from 1 bit upwards, and the operations may include arithmetic instructions, logical instructions and certain others, familiar to every professional computer programmer, such as conditional and interrupt-handling operations. Thus the microprocessor is just one example of a very broad class of monolithic digital elements, using one of several large-scale integration (LSI) technologies to implement as many as 10^5 components on a single semiconductor chip perhaps only 25 mm^2 in area.

Not surprisingly perhaps, the very rapid evolution and exploitation of microprocessors has been accompanied by a corresponding growth in publicity, some of which has been not altogether accurate. There has emerged a mythology about microprocessors or, at the least, a certain amount of confusion. Probably the most widespread myth is that a microprocessor is a microcomputer which, still, it patently is not. Probably one should not be too pedantic about this, and anyway there are many different kinds of stored-programme digital computer, but all of them have to have a memory, a control unit for instruction sequencing and some means of input and output as well as the processing section. So the microprocessor is nothing more than one component of a computer although, admittedly, a very powerful component indeed.

A much more dangerous myth is that it is easy to replace minicomputers by microprocessor systems and presumably, because the cost of microprocessors is so low, that it is possible to build a microprocessor-based minicomputer at a cost much lower than that of commercially-available minicomputers. And so we have seen numerous examples of minicomputers fabricated by the do-it-yourself process. The truth, unfortunately, is that, if all the component costs are really taken into account (including power supplies, circuit cards, casing and so on) and fabrication costs properly included, then it is almost impossible to compete even with the hardware costs of small minicomputers supplied to equipment manufacturers (the so-called 'naked' minicomputers, with no peripherals or other trappings). And this is not the least surprising, for minicomputer manufacturers have been making use of modern LSI components just as much as anyone else. However, if the fact is included that even the most modest minicomputer arrives with some software, then any thought that an individual can compete economically in synthesising a minicomputer just cannot be supported.

A more subtle myth is the claim that, because microprocessors are inexpensive, it is possible to produce at much lower cost a computing system that is comparable in performance to that of large general-purpose computers. Such claims are generally supported by demonstrating that microprocessor-based computing systems can be built with certain instruction execution times comparable to those of some chosen large computer. The more outspoken of those making these claims then go on to conclude that anyone using the large computer on a shared basis would do well to abandon this enslavement and turn instead to a 'personal' computer based on microprocessors. The millennium has, unfortunately, not yet arrived, and the reason is of course clear. It is simply that, although it is indeed possible to achieve comparable execution times for certain operations, as for example adding two integers, this is just hopelessly inadequate to achieve the performance of a large computer for calculations of a general nature.

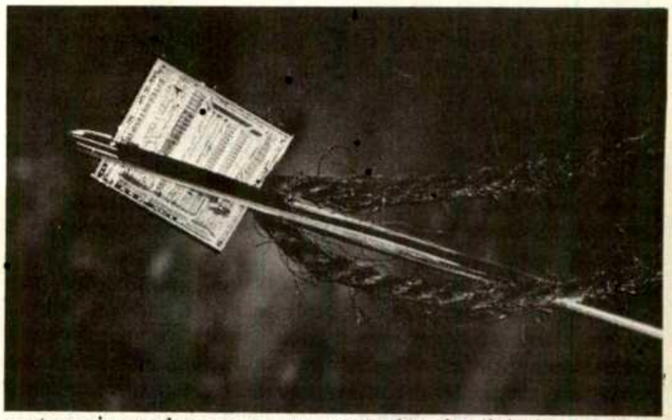
Large computers achieve their performance precisely because of their very extensive repertoire of operations, and also because of their complex internal organisation which allows many different concurrent activities. If this performance is required, then the complexity, and hence cost, of the large system is inescapable. That is not to say that the architecture of modern large computers is the best that can be imagined, nor that a large computer is best for all purposes; just that modern large computers are fairly well matched to the requirements of most large data-processing and scientific calculations, for which a microprocessor-based alternative would be inadequate.

Of course there may be certain special computational tasks that only involve just those operations that can be implemented well with microprocessors; in this case it may well be the best choice to use the microprocessor system. But, even here, the problem has to be one which occurs frequently—otherwise it may still be much more economical to use a conventional computer inefficiently. It must be emphasised here that, just as in the case of minicomputers, large systems use LSI techniques where they can and if they are costly, it is because of all the general facilities that they possess. Microprocessors have no monopoly of LSI technology.

So what is it that microprocessors offer that has led to such an upsurge in their numbers? The most important attributes appear to be small size and low cost, but these relate to the microprocessor as a digital systems component, and not to such things as complete computers. And the advantages in using microprocessors stem from the fact that these attributes enable them to be used either where an application requires large numbers of processors or where processors need to be built into some device or other. Moreover, in applications where the processing task is completely defined and does not need to be changed, there can be a very significant economic advantage in using a microprocessor system tailored to the task rather than use a more versatile minicomputer. The advantages of microprocessors when used in these 'turnkey' systems increase tremendously when the number of similar systems is great. Such problems had been tackled in the past by building special-purpose electronic systems, but these were generally expensive and very difficult to modify. Microprocessors are not only much less costly for these purposes, but also more reliable and, more important, they allow easy evolution from one system to another by changing software.

The real benefit of microprocessors has appeared in computer peripheral devices, especially terminals, and in instrumentation of all kinds. So we have seen a dramatic change already in data presentation from instruments to human beings, and in every application where electronic systems have to respond in an adaptive way to external conditions. This introduction of so-called 'intelligence' into electronic systems has transformed the operation of a wide range of systems, from oscilloscopes to washing machines, from missiles to traffic lights, from computer terminals to automobile electronics. What was costly and complicated to do before using conventional hard-wired electronic components has now become inexpensive and relatively simple to implement.

This trend towards replacement of hard-wired electronic logic by software-programmed microprocessor-based systems is nowhere more apparent than in digital communications, itself one of the most rapidly growing technological fields. Already the use of microprocessors in coupling remote devices to computer networks is commonplace, but we are witnessing only the beginning of this trend. However, all these applications generally involve the use of only a few LSI devices for each unit of equipment, and we need also to remember the other area mentioned, where many microprocessors are used together.



Ferranti

For many years now there has been the idea that what is difficult to do on a conventional sequential-processing computer might be much easier to do on an array of many coupled processors all operating in parallel. Computational problems which either have intrinsic parallelism or can be suitably formulated in terms of some parallel algorithms exist in many different fields, but their solutions have been impeded by the lack of appropriate hardware. Although attempts have been made to implement parallel computer systems using conventional hardware, these attempts have been immensely costly. Now, with the advent of microprocessors, the construction of parallel processing systems has become a real economic prospect and, together with it, the promise of effective solutions to a whole new class of problems.

So, although there is a mythological element in what is being claimed for microprocessors which sometimes distracts certain sectors from the realities of the situation, it is no myth that microprocessors have made a most fundamental impact on many different fields. Microprocessors are already transforming both the construction and the exploitation of an immense range of instruments, appliances and systems, and the signs are that this trend is only a beginning. But perhaps it is as well to end on a note of caution and to mention a final myth—namely that microprocessors are easy to use, and that it is just as easy for hardware designers to employ them as it was for them to design circuits using conventional integrated circuits. What is overlooked here is of course software, which many circuit designers are seeing for the first time.

It is probably the case that, except for a few talented individuals or for very trivial tasks, it was never particularly easy to program a computer effectively in machine code, and not only are microprocessors no exception here but they are also rather primitive. The solution to this problem is well-enough understood, for example by using what are termed high-level techniques to insulate the microprocessor system user or designer from all the details of particular system components. This solution will take a long time to establish since it depends upon agreement about standards and conventions, among other factors, and these do not yet exist. However, even with high-level techniques, it will still be necessary for hardware designers to be familiar with software. Indeed, they will no longer be circuit designers but rather systems engineers. For this to come about, and for the full potential of microprocessors to be realised, we will have to adapt our educational system to meet the new needs of such systems engineers. □

Freedom for whales

The great whales need protection from man. **Ray Gambell** describes the efforts to provide it

THE control of whaling by the International Whaling Commission (IWC), which regulates about 90% of whaling activity throughout the world, has changed very considerably in recent years. There is now a long term management policy aimed at bringing all whale stocks to their most productive levels. Stocks which have been reduced below these levels in the past are given total protection from hunting so that they can rebuild at the fastest possible rate. All management decisions are now based only on the best scientific advice available on the condition and sustainable harvesting capacities of the stocks. Previously the economic arguments of the whaling industry weighed very heavily in decisions taken on the number of whales which were allowed to be caught and the stocks were successively overtaxed to varying degrees.

This major change in management policy started in 1965 but developed more rapidly after the 1972 UN Conference on the Human Environment in Stockholm at which a three-part resolution on whaling was adopted. It called for the strengthening of the IWC, an increase in international research on whales, and a ten-year moratorium on commercial whaling.

Ever since the IWC was set up by the International Convention for the Regulation of Whaling, signed in 1946, the secretariat had been provided on a part time basis by the UK Ministry of Agriculture, Fisheries and Food. In recent years it became clear that the part-time secretariat had difficulty in meeting the increasing demands placed upon it and so in 1976 the Commission established a full-time secretariat headed by an experienced whale biologist. The offices of the Commission have now moved from London to Cambridge, where there are a number of research instituions concerned with whales and other marine mammals. The secretariat is now able to devote itself completely to the development of the Commission's activities, including publicity, publications and the general servicing of the Commission's day-to-day requirements.

International research

A great deal of current knowledge of the biology, life history and status of the stocks of the great whales has been gained with the generous cooperation of the whaling industry itself. Biologists have been able to collect and analyse materials from the whale carcasses during normal commercial operations and facilities for sighting and marking programmes, which would not otherwise have been undertaken have been provided. Inevitably, with the reduction of the whaling industry in recent years, the scope for research based on commercial operations has declined. This is particularly noticeable in terms of the sighting areas covered by the fleets, which now provide the only records of the protected species.

Whale research on an adequate scale for proper global management is very expensive. In 1975 the Scientific Committee of the IWC put forward detailed proposals known as the International Decade of Cetacean Research (IDCR), for research on the distribution and status of the stocks of whales in the southern hemisphere, North Pacific, and North Atlantic Oceans. They have been submitted to the United Nations Environment Programme as one possible funding agency. It is estimated that the first year of this ten-year programme will cost $2.4 million at 1974 prices and, so far there has been no progress in obtaining funding of this magnitude. The delay has been partly brought about by a number of bodies awaiting the research proposals from the Food and Agriculture Organisation (FAO) Mammals in the Sea Scientific Consultation held in Bergen in September 1976.

In the meantime the IWC has set up its own voluntary research fund. Only a few contributions have been received so far, but it is hoped that a number of the IDCR proposals can be funded and implemented through this research fund. In addition, of course, the various national research groups continue their own programmes.

When the IWC considered the call for a total moratorium on commercial whaling it accepted the advice of its Scientific Committee that such action could not be justified scientifically since prudent management required regulation of each stock individually. Nevertheless, the Commission did formulate and adopt precise guidelines for the control of whaling based on the concept of Maximum Sustainable Yield (MSY). All stocks of whales are now classified into one of three categories according to the advice of the Scientific Committee:

- Initial Management Stocks, which may be reduced in a controlled manner to achieve MSY levels or optimum levels as these are determined.
- Sustained Management Stocks which will be maintained at or near MSY levels and then at optimum levels as these are determined.
- Protection Stocks, which are below the level of sustained management stocks and will be fully protected.

All whale stocks have a natural capacity for increase and a natural rate of mortality. At their initial level these two factors balance one another so that the stock remains more or less in equilibrium. As the stock is reduced the pregnancy rate rises, the age at which the whales start to reproduce falls and recruitment increases. At some particular stock level the surplus of recruits over natural deaths reaches a maximum—the MSY—which can be safely harvested without reducing the stock size. At stock sizes below this level the surplus of recruits over natural mortalities declines until another equilibrium position is reached at very small stock levels.

The Scientific Committee has responsibility for identifying stocks of all species of large whales and classifying them according to these categories. The classification is revised annually. The size of catch which may be taken from the stocks is then determined more or less from automatic rules. If a stock is to be judged to be substantially smaller than the MSY level total protection is declared. If it is larger, catching is permitted under quotas which should allow a controlled reduction of the stock towards the MSY level. If the stock is already near the MSY level annual quotas are set with the intention of maintaining the stock at about that size. The rules for determining catch limits allow for possible errors in MSY estimates. For example, no more than 90% of the estimated MSY can be taken whatever the classification of the stocks. This gives a margin of 30% either way in the estimation of the MSY stock level with a symmetrical yield curve. There are also supplementary rules for determining the rates of catch when there is insufficient knowledge to assess the status of the stock, especially when exploitation has only just begun, and also when a stock has apparently been exploited at a sustainable level for many years.

Scientific advice

Despite the advances made by the IWC in bringing its house into order in recent years, there is still considerable public interest and debate over the way in which the whale stocks are harvested. One area of criticism concerns the activities of the Scientific Committee itself. There is much discussion

---

Ray Gambell is Secretary to the International Whaling Commission.

over the concept of MSY as a basis for management. The Scientific Committee is very much aware of this problem and is open to any proposals which would help it in its task of assessing, classifying and offering advice on the regulation of the whale stocks. For the moment, however, the MSY concept is one which does give practical guidelines for the management of the whaling industry which can be kept under constant review. It also allows for new factors to be introduced to develop the idea of optimum stock levels.

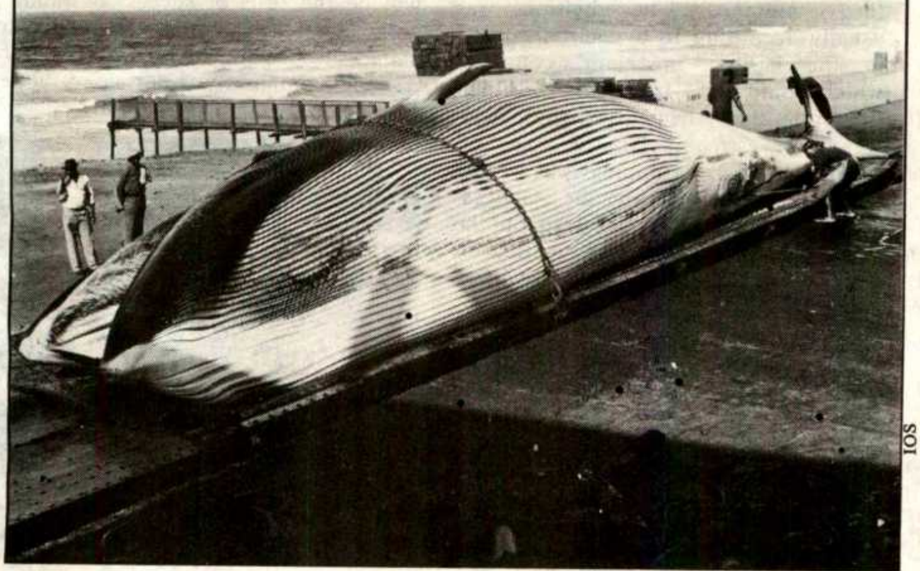
The International Union for the Conservation of Nature and Natural Resources has called for the replacement of the MSY concept by more ecologically based criteria but unfortunately, it is not yet possible to quantify such a basis for management. Discussions are going on between the IWC Scientific Committee and the IUCN with a view to developing these ideas.

A further source of difficulty is the extent to which the Scientific Committee's activities and discussions are available for public scrutiny. Because it meets in the two weeks immediately preceding the Commission's Annual Meeting held in June every year, there is no possibility of publishing the reports of its work before the meeting. This has happened because the Committee must have the latest catch statistics from the Antarctic whaling season which finishes only a few weeks earlier. However, all the scientific papers contributing to management decisions are available immediately after the meeting, and most of them are published subsequently in the Commission's Annual Report.

The Commission has been criticised as a club for exploiters but the majority of the sixteen member nations do not catch whales commercially. Also, any government may adhere to the 1946 Convention and so play a full role in the conservation and management of the whale stocks. When the Commission was first set up it recognised that specialised agencies related to the United Nations would also be concerned with the conservation and development of whale fisheries. It therefore agreed to decide within two years of the Convention's enforcement whether it too should become a UN agency. In 1950 it resolved that it should remain an independent body, but at the same time decided to maintain its close association with the FAO. The question of IWC affiliation to the UN has not since been raised within the Commission.

The 1946 Convention is currently being reviewed and a meeting is being planned of plenipotentiaries from all significant whaling countries or countries with stocks of cetaceans off their coasts to elaborate a new cetacean convention. It is very important that all whaling should be under unified international control, for if unregulated catching goes on there is little prospect for the survival of whales as a valuable resource and component of the marine ecosystem.

Although only some 10% of the world's whaling is carried out by nations which are not members of the IWC, their catch represents all or a major part of the whaling activity in certain parts of the world. For example, off the coasts of Chile and Peru these two nations are the only countries actively whaling, while the Spanish and Portuguese catches in the temperate Atlantic are the only ones in that area. In addition, catches by Korea and a Somali registered vessel overlap with IWC members' operations. The IWC has noted that these activities are seriously weakening its conservation measures and it has repeatedly called on these countries to adhere to the 1946 Convention. So far, diplomatic approaches by individual governments and by the United Nations and various of its specialised agencies have met with a negative response.



Pin whale on the Durban whale track

IOS

International inspection

The Commission's regulations are enforced by whaling inspectors appointed by the flag nation of each catching operation. They report on any infractions and carry out prosecutions through their national jurisdiction. The Commission has also established an International Observer Scheme, whereby observers are exchanged between nations which are in or operate within the same geographical areas. Thus, Japan and the USSR exchange observers on their factory ships in the Antarctic and in the North Pacific. Land station operations in Japan receive observers from the United States, and the Icelandic whaling station has a Canadian or Norwegian observer. A similar exchange is planned between Australia and Brazil, the two Southern Hemisphere land station operations with the IWC.

The observers report directly to the Commission on the manner in which the whaling operations and the inspection schemes are carried out and check that the various regulations governing whaling activities are properly implemented. It has been argued that such an interchange between nations with common interests is not sufficiently independent and that observers from non-whaling nations should be placed at the various whaling factories. This is a matter for international agreement but it must be recognised that the present observer schemes are a significant step forward in the control of the whaling industry on a global scale.

The history of the regulation of whaling this century is generally one of failure. A number of stocks have been seriously depleted in every phase of whaling activity, for whales can be caught more quickly than they are able to reproduce. Nevertheless, the recent advances in the organisation and actions of the IWC make the future look more hopeful. Although there are still many difficulties and many problems of a scientific and administrative nature the present direction of the IWC and its stated intention to manage the stocks in a responsible fashion give cause for future optimism. □

Now, an implementation problem

Robert Stein writes on the United Nations Water Conference which took place last month

The UN Water Conference finished its work on 25 March in Mar del Plata, Argentina, and the ripple was slight. Most of the reports coming out of the conference said nothing much happened, which was taken by reporters on the scene to be either good or bad. That no serious political controversy disrupted this conference in the way that political issues tore apart the end of the UN Human Settlements Conference in Vancouver last June was certainly positive. There was a lot of serious discussion both by those with technical expertise and those concerned with the political implications of the various uses of water. On the negative side, the lack of exciting controversy did not result in very many concrete advances, and this is seen as a failure of the conference since the problems are still waiting to be addressed.

But what was the conference trying to do—and did it come at all close to accomplishing its purposes? The representatives who journeyed many thousands of miles to participate in the conference—over one thousand of them from 116 states—had been given documentation which contained both good and bad news. There was enough water globally but, as Gilbert F. White put it in the basic UN background paper, "Frustratingly, it tends to be available in the wrong place, at the wrong time, or with the wrong quality." Yet for the developed world, the bulk of the problems had until the past few years not been theirs. Pollution, yes, but there was little expectation that a UN conference could help advance their perception of the problems. Then in the summer of 1976, water shortages in northern Europe, and the lack of snow in North America the following winter woke others up to the fact that drought was not merely a problem for the Sahel. Sound water management begins at home.

At the same time this conference, ill prepared as it was (the preparatory committee meeting in January had only one day to review the draft of the plan of action), had a specific charge, provided by the UN Human Settlements: to consider targets for supply of potable water and waste disposal.

Many of the countries of the underdeveloped world addressed water supply as their most pressing problem. Kenya, Tanzania, Nepal, and Pakistan all issued pleas to the conference for help. A number of African countries called for a new special fund to assist countries in water supply and waste disposal—a cry which was not answered. Instead, the conference adopted a resolution calling for a study to figure out how to finance a variety of water development projects, a study which would not exclude the possibility of a fund.

Additionally, and more importantly, the conference approved a resolution put forward by Argentina, the host government, which called upon governments needing improved water supply and waste disposal systems to prepare programmes and plans by 1980 to to reach the Habitat goals of water for all rural and urban areas by 1990. These plans would then be reveiwed to determine how they could best be funded. Interestingly, the problems of maintaining broken-down systems, which are usually ignored, were made an integral part of the recommendations. The resolution was much less specific on which body or organisation would help with the implementation, but that was left for the UN's Economic and Social Council to work out. The conference dealt only generally with problems of water in arid lands and drought, preferring to let the Deserts Conference, this August, tackle that issue.

Management of shared river basins contributed greatly to whatever substantive disagreements took place at the conference. The division was usually according to a country's place in the basin: 'upstream' countries which could hold back water or pollute it to the detriment of those who were 'downstream' banded together, providing such groupings as India against Bangladesh on the Ganges; Turkey against Syria and Iraq on the Euphrates; Brazil against Argentina on the Parańa; and Germany, Switzerland and France against the Netherlands on the Rhine. The resulting recommendation was clearly a political compromise urging cooperation and using the waters of the basin equitably in accordance with principles of international law. Advance consultation was also watered down, with no mandatory requirements. The work of international legal bodies was also encouraged, though given past performances, many disputes—acrimonious as well as peaceable—will arise before these groups conclude their work.

The conference ended positively. An attempt to introduce a statement, which most aptly would have been called the "Declaration of Mar del Platitude", was defeated; instead the recommendations themselves were enshrined. But after the delegates packed their bathing suits and stacks of documents, and left the shining sea and all the plain-clothes police behind, what is next?

UN Conferences can only be a reflection of the willingness of member states to do something. Agreeing to a fund does not necessarily provide any real money to build water supply systems or irrigation works. A conference must—and the UN Water Conference just barely did—supply tools enabling countries and international aid-giving agencies to act in specific directions if they so choose. They are not law making conferences, like the UN Conference on the Law of the Sea is meant to be, nor can they be in two weeks. The proof is in the implementation, a part of the conference process too often ignored both by governments and the UN system.

So the questions remain. How will governments react to the proposals when they are presented to the UN Economic and Social Council in July? How many governments will make efforts—which they otherwise would not have done—over the absence of the water supply programme or the provision of aid and technical assistance to those that need it? How will the conference affect programmes of international agencies such as the World Bank, WHO, FAO, WMO, UNDP, UNICEF and all the others who came to the conference to make sure they weren't cut out of the action? These will be the tests of success or failure, and though it is too early really to gauge success, the record of the international community is not a very hopeful one. □

Robert Stein is Director of the North American Office of the International Institute for Environment and Development

PROFILE

Kenneth Owen on Sir Ieuan Maddock

Bread-and-butter or exotica?

Sir Ieuan Maddock

A CHOICE trio gave details of the Labour Government's new Ministry of Technology at a Millbank Tower press conference in November 1964—Frank Cousins, trade union leader turned minister; C. P. Snow the author, alias Lord Snow, a junior minister; and Professor P. M. S. Blackett, deputy chairman of the minister's Technology Advisory Council. Dr Ieuan Maddock at that time was with the Atomic Energy Authority at Aldermaston. The following September he moved over to Mintech at the invitation of Dr John Adams to help get the fledgling ministry moving.

At the end of last month, six ministers and two ministries later, Sir Ieuan Maddock, FRS retired as Chief Scientist at the Department of Industry. He remains acting director of the National Physical Laboratory.

A tough, ebullient Welshman, he had needed both toughness and ebullience to steer industry and government research establishments towards what he saw as the right kinds of technology. In the process he offended both high-technology industry and the establishments: he was bruised by the expediency of politicians.

The concept of Mintech had been generated primarily by Blackett, who knew at first hand how science had been harnessed to immediate national objectives during the 1939–45 war and who believed that industry could now be regenerated by a similar approach. Maddock joined Mintech as a deputy controller. It was then a very small ministry, responsible for only four industries—electronics, computers, telecommunications and machine tools. Mintech expanded with the transfer of the engineering industry divisions of the Board of Trade in February 1966 and Maddock went on to head five industrial divisions.

Mintech also broadened in scope to deal with basic industrial structures, not just technology. One facet of this approach led to the setting-up of ICL as Britain's national computer company. Various other programmes were mounted to stimulate the application of advanced machines and techniques in industry. "By the summer of 1969", Sir Ieuan recalls, "we were really beginning to get results".

Then came a body-blow—the change of government in 1970 which abolished Mintech and put its initiatives into reverse. "The new government classified everything we were trying to do at Mintech as 'interventionist'. The shutters came down absolutely and completely. You were guilty until you could prove yourself innocent. A lot of schemes were scrapped long before we had a chance of finding out whether they were good or bad".

In his work as Controller of Industrial Technology at the new Department of Trade and Industry (DTI), Maddock was becoming more of an administrator, working on, among other things, the future of the steel industry. "By that time I had moved a fairly long way away from science and technology". This was rectified in February 1971, when he was appointed to the new post of Chief Scientist at the Department. He was to be responsible for the general strategy and coordination of the Department's research activities, while retaining his responsibilities for the DTI sponsorship of the steel, electronics and computer industries.

"At that time", Sir Ieuan says, "I found it personally very difficult. I was dedicated to what we had been doing at Mintech and I was seeing it dismantled. I was having to fight rearguard actions all the way, saying 'Look, you're throwing all kinds of babies away with the bathwater'—and subsequent events proved that to be right.

"I have to confess I didn't enjoy that part of my life at all. In nearly 40 years of government service it is the only period I can recall when I was really pretty unhappy with my environment".

Fresh air blew in with the Rothschild proposals, fully supported by Maddock, which introduced the customer–contractor principle into government R&D spending. "With the dip in my moral factor at that time", Sir Ieuan says, "this gave me something to get my teeth into".

The DTI itself was not a customer department, in the way that Defence was; how should the Rothschild principles be applied? Maddock's solution was to set up a group of industry–government research requirements boards to act as proxy customers, decide priorities and allocate funds. As their programmes came under scrutiny from the boards, the government laboratories hated the whole exercise, Sir Ieuan admits cheerfully. The balance of R&D spending changed, with less being channelled through the establishments and more through the research associations (and through industry).

On public occasions throughout his time at Mintech, DTI and DoI, Sir Ieuan has repeatedly stressed the importance of the bread-and-butter industries and the dangers of pursuing high-technology exotica. The transfer of existing technologies is more important than the creation of new ones; this has become his personal crusade.

"It's not so much the money, it's where you address the best intellects", he says. "The staff list at Harwell in about 1954 contained the cream of the cream; what a hell of a risk that was". The best Japanese brains, meanwhile, were going into the engineering and manufacturing industries. "That's why they're knock-hell out of us now".

Thus Sir Ieuan finds himself "a bit of a renegade" on the Joint European Torus, because "if JET comes to Britain it's going to suck in another new generation of cream talent"—talent that is sorely needed in the engineering industries.

During his time at the three ministries, Sir Ieuan has worked with seven ministers: Cousins, Benn, Rippon, Davies, Walker, Benn again and Varley. His most stimulating time was at Mintech, working with Benn as minister and the formidable Sir Richard (Otto) Clarke as Permanent Secretary.

He quotes two main overall conclusions: First, the tragedy of 1970 when promising Mintech projects were killed off indiscriminately; clearly this still hurts. Secondly, the fact that all the various microeconomic attacks on particular industrial problems will be of little benefit without a stable, healthy macroeconomic background. "Unless you've got that", he says, "technology will not flow".

From 63 to 400?

Colin Norman in Washington examines the implications for nuclear power of last week's energy proposals from President Carter

"THIS has been an exceptional week", President Carter declared last Friday during a packed press conference. Indeed it has. It began with a sombre televised address in which Mr Carter suggested that overcoming the energy "problem" would be a little like waging a war, and ended with a press conference in which he defended his strategy for winning that war. The strategy itself was unveiled on Wednesday, and it has so far achieved the distinction of uniting commentators in their observations that dramatic measures may be needed, but that some of Carter's measures should be resisted.

The strategy consists of a bold set of measures designed to curb Americans' seemingly insatiable appetite for energy by raising energy prices, taxing heavy users, and returning the revenues back into the economy in the form of rewards to people who conserve (see box). The plan is also designed to decouple industry from its reliance on oil and gas by forcing more widespread use of coal, and it also attempts to encourage the use of light water reactors. The emphasis is on the near term.

The proposals for nuclear power are particularly interesting. On April 7, Carter announced that, in the interests of curbing nuclear proliferation, the Administration will defer indefinitely its plans to reprocess commercial nuclear fuel and that it will sharply downgrade the breeder reactor programme. Last week, those decisions were spelled out in more detail, but at the same time, Carter made it clear that the Administration does not intend to turn its back on nuclear power. Far from it. Carter in fact announced that the Administration will seek to remove some of the roadblocks to licencing nuclear plants, step up attempts to find suitable burial sites for nuclear wastes, and completely change direction on uranium enrichment by building a large new enrichment plant using gas centrifuge technology instead of the present gaseous diffusion process.

The intention, in short, is to rely on light water reactors, without plutonium recycle, to meet a growing share of energy needs for at least the next 25 years, but to keep the breeder reactor effort ticking over as insurance against the possibility that the United States will need to move into the plutonium economy early in the next century. According to officials of the Energy Research and Development Administration (ERDA), the number of light water reactors in the United States is expected to grow steadily from the present figure of 63 to between 300 and 400 by the turn of the century.

The nuclear strategy rests on some critical assumptions, however, perhaps the most important of which involves the size of the United States' uranium reserves. Proven reserves now amount to about 1.8 million tons, which would be sufficient to fuel about 300 reactors throughout their lifetimes—barely enough to meet ERDA's projections for domestic nuclear expansion this century, with none left over to meet contracts from abroad. ERDA is, however, launching an intensive programme to assess uranium reserves more accurately, and acting ERDA Administrator Robert Fri said last week that he is "guardedly optimistic" that proven reserves will swell to about 3.7 million tons. There is some question, however, whether the electricity industry, faced with uncertainties in long-term uranium supply and with no guarantee that plutonium recycle will be available to help stretch nuclear fuel supplies, will be enthusiastic about purchasing nuclear plants.

As for the breeder reactor programme, there is still some confusion about the Administration's intentions. One thing is certain, however: the effort is being sharply cut back and it no longer occupies pride of place as the top priority programme in the United States' energy research and development effort. Last week, Carter proposed that the programme's budget be reduced by $173 million next year, in addition to a cut of nearly $200 million which he proposed in February. The plan now is to complete the fast flux test facility, a test reactor now under construction in Washington, but to defer indefinitely plans to build a large demonstration reactor on the Clinch River in Tennessee. That project, which was to have cost more than $2,000 million, will be redirected to focus on alternative breeder reactor designs which present less of a proliferation hazard. The exact nature of the programme has not yet been

The central feature of President Carter's energy strategy is a carrot-and-stick arrangement of rewards and penalties designed to break the country's addiction to vast quantities of energy. The carrot comes in the form of an assortment of tax breaks and other financial incentives for people who insulate their homes, buy small cars or install solar heaters. The stick is a complex set of proposals which will lead to higher energy prices, and the threat of stiff taxes on gasoline and on gas-guzzling cars. The goal is to reduce the growth in energy demand from its present level of about 3.5% a year to about 2%.

Coupled with those efforts to stimulate conservation is a series of proposals designed to increase the use of coal and light water reactors. Longer-term energy supply options will also receive modest increases in research support, but the emphasis is mostly on efforts likely to produce relatively quick results.

The major elements of the plan:

Oil and gas prices: A complex set of taxes coupled with price increases for newly-discovered domestic crude oil would cause oil and gas prices to increase until they "generally reflect the true replacement cost of energy". At present, prices are kept artificially low by a variety of controls.

Gasoline taxes: Unless gasoline consumption is reduced according to specific targets, tax increases of 5 cents per gallon will be imposed each year, beginning in 1979, until the total tax reaches a maximum of 50 cents.

Gas guzzler taxes: New cars which fail to meet gasoline consumption standards would be heavily taxed, and the revenues would be returned in the form of rebates to people who buy more efficient cars. For example, 1978 model cars which get less than 12.5 miles per gallon would carry a tax of $449, while those which get more than 39 miles per gallon would be given a rebate of $473. By 1985 cars with those consumption levels would carry taxes and rebates of $2,488 and $493 respectively.

Insulation and Solar heating: All new buildings will have to meet insulation standards. Homeowners who insulate their houses would be entitled to income tax credits of 25% of the first $800 and 14% of the next $1,400 spent on conservation measures. Similarly, people who install solar equipment before 1985 would be able to claim 40% of the first $1,000 and 25% of the next $6,400 as a tax credit.

Nuclear power: Light water reactors without plutonium recycle will have an increasingly large role. New gas centrifuge plants will be built to enrich uranium for reactor fuels, more funds will be pumped into efforts to find suitable waste disposal sites, and an attempt will be made to reduce the present 10-year licencing process for nuclear plants to 3 years.

Coal: Many industrial facilities would be forced to switch from oil and gas to coal, and they would also be required to use the best available technology to control pollutants. Research and development on processes designed to produce synthetic oil and gas from coal would be stepped up. In addition, Carter will establish a commission to report by October this year on the health effects associated with mining and burning large quantities of coal. And a new research programme, costing $3 million, will be launched to look into the so-called greenhouse effect.

worked out, however, and Administration officials suggest that it will be weeks, if not months, before it is.

As for the plan to build a large centrifuge enrichmenmt plant, this again is coupled with Carter's moves to curb nuclear proliferation. In 1974, the United States closed its order books for long-term supplies of enriched uranium to other countries because of projections that US enrichment capacity would be used up. The move is said to have prompted many countries to seek alternative sources of supply, and it may have been a key factor in persuading Brazil to negotiate the purchase of an enrichment plant from West Germany. Carter has therefore announced that the United States will re-open its order books, and that a supply of enriched uranium will be guaranteed to those countries which renounce the development of nuclear weapons.

To meet the projected demand, a large centrifuge enrichment plant will be constructed at a cost of some $4,400 million. So far, all US enrichment has used the gaseous diffusion process, and previous plans called for expansion of an existing diffusion plant at Portsmouth, Ohio. Administration officials say, however, that the gas centrifuge process, which has been developed in secrecy at Oak Ridge, Tennessee, is now ready to be commercialised. So far, however, no site for the new plant has been chosen, though hints that it may go to Oak Ridge, to compensate for cancellation of the breeder reactor project there, have sparked loud protests in Portsmouth.

In addition to relying on a modest expansion of nuclear generating capacity, Carter's plans for medium-term energy supply also envisage considerable expansion in the use of coal. He has proposed measures to force industry to convert from oil and gas to coal, announced large increases in research and development efforts aimed at producing synthetic oil and gas from coal, and recommended a number of regulations to reduce the environmental consequences of such an expansion.

There is, however, one potential environmental problem which could prove intractable: the so-called greenhouse effect which may lead to changes in the global climate from large increases in atmospheric carbon dioxide. Carter announced last week that a major study of the greenhouse effect, costing $3 million, will be launched this year.

Carter's energy plan will now be picked over on Capital Hill, and already special interest groups are clawing at it. The debate is likely to rage for the rest of this year. ☐

GEOS

Hope from despair?

Stuart Sharrock in Washington and Chris Sherwell in London report on the ill-starred launch of Geos, the European Space Agency's scientific satellite

On Tuesday of this week a group of space scientists and another of space engineers met separately on opposite sides of the Earth to discuss an event that occurred above the globe halfway between them. Last Wednesday, twenty minutes after a Thor-Delta 2914 rocket had taken off from Cape Canaveral only 0.2 seconds later than its scheduled lift-off of 05.15, the hopes of 11 research institutes from eight member countries of the European Space Agency turned to despair as a malfunction during the separation of the second and third stages of the rocket caused the third stage to separate early. It meant that the payload, the world's first geostationary scientific satellite known as Geos, could not achieve its planned orbit and that seven experiments which took years to prepare might no longer be done.

In fact the despair looks as though it may have been premature. For although the engineers from the rocket manufacturers McDonnell Douglas gathered in California to discuss the Delta's acknowledged failure, the scientists who met at the ESA's Space Operations Centre at Darmstadt in West Germany did so a little more optimistically. On the previous day Geos had been placed in an elliptical orbit whose apogee, at 38,498 km, was easily as high as the originally intended circular orbit.

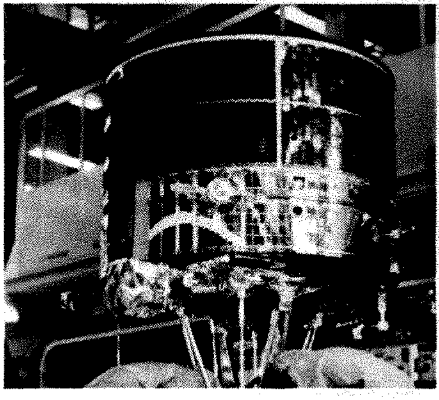
The difference, of course, was that the new orbit, not being geostationary, would not allow the satellite to be permanently within sight of the Darmstadt ground station. It is understood, however, that not all the data obtained over each 24-hour period would have been used anyway. The new elliptical orbit, selected to maximise the return of scientific data, has a perigee of 2,131 km and an inclination of 26.85°. It is traversed every 12.06 hours by the satellite, which could now be within sight for some 10 hours a day.

As the scientists gathered to decide which experiments to pursue and data to collect, ESA officials were pleased to have retrieved, if only partially, a mission which at first looked on the very edge of disaster. The spacecraft and third stage assembly should have spun up to 97 revolutions per minute before separating from the second stage. This spin stabilisation would have ensured that the third stage had an accurate trajectory during its burn; without it, the spacecraft tumbled around into the wrong orbit, though it was stabilised soon thereafter.

The spacecraft could not have been allowed to stay indefinitely in this so-called transfer orbit because it went through zones of high radiation which might endanger the experiments and decrease the total active lifetime of the spacecraft. To stay in that orbit also served no useful purpose: it was not on the magnetic field lines connected to the auroral zones of the Arctic and Antarctic, and the experiments would probably not work with the field and particle intensities so high.

The original intention was that the spacecraft should be injected into an elliptical transfer orbit (apogee 35,500 km, perigee 230 km) and then be boosted on the fourth apogee to a circular orbit synchronised with the Earth below. That the European-built solid-propellant apogee booster motor responsible for this task placed Geos in the elliptical orbit it now occupies is a cause for comfort, even though the motor could not be used twice to achieve a circular orbit. But then so much could so easily have gone wrong.

The effect, ironically, is that Geos is now placed in a fashion that had been expected of the ESA's spare 'qualification' geosynchronous satellite which was due to be sent up in 1979 atop a European Ariane launcher now being developed. It remains possible that this back-up satellite will be upgraded to become the 'true Geos', but it will cost the ESA another 13 million units of account to purchase the launch from NASA—a cost which is not recoverable for last week's launch under NASA's no-loss-no-profit contracts. Although the ESA Council is due to meet next week, it is unlikely to discuss this idea of inverting the roles of the two satellites. ☐



Quarks out of the bag?

In a paper given at the American Physical Society Spring Meeting in Washington DC, Drs W. M. Fairbank, A. F. Hebard and G. S. LaRue of Stanford have presented evidence for the existence of fractional electric charges. The experimenters emphasise that they are claiming the existence of fractional charge; they do not mention quarks.

Their experiment is a sophisticated version of the classic Millikan oil-drop apparatus. A superconducting niobium sphere 0.25 mm in diameter is floated in a magnetic field and its net residual charge deduced by analysing its behaviour in an oscillating electric field, the net charge can be altered by integer values of the electron charge e, by using a radioactive source. Fractional charges of $\frac{1}{3}$ e or $\frac{2}{3}$ e carried by a quark would be detected as the sensitivity claimed is 1% of the electron charge.

The most severe background is electric and magnetic dipole moments on the spheres which mimic the effect of a fractional charge. These dipole backgrounds are now understood and have been eliminated, according to the experimenters.

Of eight spheres measured, two show evidence of fractional charge: the first was seen last September and the second in mid-February. One had a measured residual charge of minus 0.331 ± 0.070 e which went to zero after handling at room temperature. A second sphere has a charge of plus 0.337 ± 0.009 e. It has been measured on three occasions and the charge remained after the sphere was taken to room temperature.

Preparation of the spheres includes heat treatment during which five spheres were supported by niobium and three by a tungsten substrate. The two spheres showing fractional charges came from the tungsten substrate set.

Why have all other quark searches been fruitless? In an interview with *Nature*, Dr Fairbank argued that searches have only been carried out on a limited variety of materials. If quarks were released in extremely energetic events during the early stages of the universe one can speculate that they go through some unknown evolutionary process to end only on heavy elements.

Initial reaction to the announcement is firstly surprise that quarks could be so abundant as to show up on two out of only eight spheres, and secondly amazement that an antiquark is seen. The experiment cannot distinguish a residual charge of $+\frac{1}{3}$ e from $-\frac{2}{3}$ e.

If these quarks are genuine they will challenge much recent theoretical work. Present understanding of quarks inside protons is that they are light and bound within the proton—to remove one would require an infinite amount of work. Heavy free quarks could be accommodated within the theory but they would be very different objects from those inside the proton and much of the aesthetic beauty of the theoretical framework would be lost.

Future plans of the Stanford team include measuring more spheres, investigating the significance of their mode of production and evaporating the material to separate and collect the charges.

Stuart Sharrock

IN BRIEF

Brenner's appointment

The UK Medical Research Council (MRC) has announced that Dr Sidney Brenner will become leader of the MRC Laboratory of Molecular Biology (Hills Road) in Cambridge on the retirement of Dr Max Perutz in 1979.

The news is little surprise for those who have heeded the rumours that followed an internal MRC report produced last year on the future of Hills Road, suggesting a radical change in organisation. The MRC has followed this, for whereas Dr Perutz was chairman of the Governing Board of the laboratory, Dr Brenner is to be its Director.

The Governing Board at present consists of Dr Perutz, Dr Hugh Huxley (whose appointment as Deputy Chairman has also been announced), Dr Brenner, Dr John Gurdon, Dr Cesar Milstein, Dr Fred Sanger and Dr John Smith. It has been collectively responsible for the running of Hills Road, with no particular power being vested in the chairman.

In 1979, however, the Governing Board will probably be disbanded. Its replacement, if any, is currently under discussion, but whatever the outcome Dr Brenner is certain to end up with a good deal of power. What is more, several of the senior staff at Hills Road will have left by the time Dr Brenner becomes Director. Dr Francis Crick has recently announced that he is to remain at the Salk Institute where he is currently on sabbatical, and David Blow has just taken up a chair at Imperial College, London. It is also rumoured that that two other senior members, both on the Governing Board, have their eyes on other posts.

Another novelty for Hills Road is the fact that it is a shrinking laboratory. The staff is to be gradually pruned by 25%, back to its 1972 level.

All told Sidney Brenner will have a considerable challenge on his hands if he is to maintain the world-wide reputation of Hills Road during the course of his Directorship, which automatically lasts (as does the laboratory) until 1987, when he is 60 years old. Dr Brenner was recently heard to say "I am going downhill and I am going with a lot of noise". Only the second part of that statement is true.

Atkinson for NSF

Richard Atkinson, a former professor of psychology at Stanford University, has, as expected, been named by President Carter to be Director of the US National Science Foundation (NSF). Generally regarded as an effective administrator well versed in dealing with Congress, Atkinson has been Acting Director of NSF since August 1976, when the previous incumbent, H. Guyford Stever, departed for a brief stint as science adviser to President Ford. Atkinson was deputy NSF director for 17 months before that. A top-flight researcher in fields ranging from the development of memory to the application of computers to instruction, Atkinson is the first social scientist to be appointed Director of NSF.

Whose power to choose?

There is now "a unique and possibly unrepeatable opportunity" to bring international action to redirect the worldwide use of nuclear power, according to Brian Johnson, author of a paper published by the International Institute for Environment and Development, *Whose Power to Choose?* At a time when President Carter is committed to controlling nuclear proliferation and the US nuclear industry gets 70% of all nuclear power station orders, there should be the opportunity, he argues, to bypass the plutonium economy by assuring countries of fuel for the thermal reactors they need, safeguarding the international community from proliferation and creating programmes to develop alternative energy sources.

To implement such proposals he suggests a reformed IAEA: its Department of Safeguards and Inspection should be strengthened, all nuclear facilities should be licenced with the IAEA to ensure security and environmental safety, and it should enforce internationally agreed measures for waste disposal. A new energy agency could be developed, independent of the United Nations but with support from OPEC and the US, to look into ways of helping poor countries shed their dependence on oil and nuclear power by developing alternative energy sources.

Uranium for Europe

President Carter's statement in last week's energy message to the US Congress that it was time "to resume uranium enrichment services" to Europe and elsewhere is likely to be well received in the European Community. The Nine's dependence on imported energy and on nuclear power was stressed heavily by the President of the European Commission, Mr Roy Jenkins, when he met Mr Carter earlier in Washington. Mr Jenkins told Mr Carter that without adequate and assured supplies of enriched uranium, European countries would be more tempted to invest in reprocessing and fast breeders.

Supplies from the United States were held up pending a review of US policy on nuclear exports: a total of almost 2,900 pounds of uranium, for various destinations around the world, was involved. Canada, Europe's other main supplier, has held up supplies too, pending full agreement on safeguards and nuclear exports.

Preparing for 1979

The ten members of the Committee on Science and Technology in Developing Countries (COSTED)—a grouping established within ICSU in 1966—gathered in London for a couple of days last week for their annual meeting. Among other things, they are understood to have discussed their position in relation to the forthcoming United Nations Conference on Science, Technology and Development, taking the view that a non-governmental group of scientists ought to participate in their individual capacities. COSTED also hopes to help in the preparation of papers by developing countries.

UK vacancies

During 1976 the British Civil Service had vacancies for about 340 scientific officers at grades up to Senior Principal Scientific Officer. About 11,000 applications were received, but even so only 250 appointments were made, the Civil Service Commission says in its annual report. It seems that recruitment of scientists is a particularly tricky business; as many as 50% of those made offers decline to take them up.

Public expenditure cuts obliged a number of major departments to withdraw entirely from recruitment in the second half of the year.

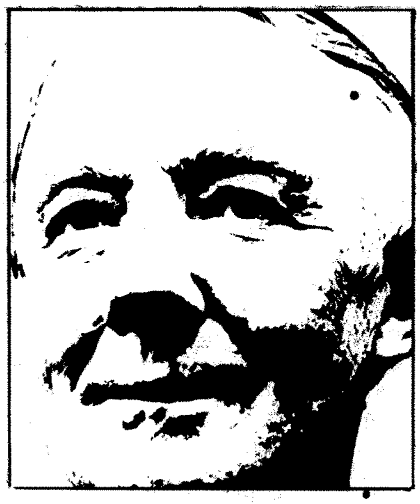
Concorde's noise

A gloomy report on Concorde noise levels has emerged from a working group of the Noise Advisory Council (HMSO, 50p). So gloomy in fact that the Secretary of State for the Environment, who is chairman of the council, specifically states that the views expressed are those of members of the council only and not of the Secretary of State.

The first operational figures for Concorde noise at Heathrow were obtained in the summer of 1975. They showed take-off noise to be on average several dB above Heathrow's statutory day-time limit of 110 PNdB at certain monitoring prints. The working group were told that an improvement of a few dB could be expected in cooler weather and when pilots became more experienced.

Operational figures for eight months of commercial operations are now available. The working group consider there has been little or no improvement on the 1975 figures, and suggest that the only way to improve Heathrow's noise climate would be to ban Concorde at night and in the evening and early morning, to restrict other jet flights at night still further, and to require Concorde operation to balance its increased noise with reductions in flights of other noisy aircraft.

Pollution economics



KENNETH MELLANBY

DURING the past ten years many writers have suggested that global pollution is the most serious hazard facing mankind. They say that if we insist on economic growth and further industrialisation and on using more energy, catastrophic environmental degradation is inevitable. This was the message of *The Limits to Growth* and *A Blueprint for Survival.* It would be foolish to deny that pollution is a problem, or that new industries may give rise to serious damage. We should welcome attempts to regulate developments such as those set out in "Suggestions for the development of a hazard evaluation procedure for potentially toxic chemicals", a memorandum from the Monitoring and Assessment Research Centre (MARC) at Chelsea College, London. But we should also recognise that many new techniques are much less polluting than those which they replace, and that any alleged correlation between the use of energy, or a rise in GNP, with pollution, is spurious.

In fact, changes are often in the other direction. London's air is cleaner in 1977 than it was in 1877, though the population has increased and far more energy is consumed. In their recent book, *The Next 200 Years,* Herman Kahn and his colleagues of the Hudson Institute suggest that vastly increased economic growth and energy consumption will be needed to ensure global cleanliness. The same view is, in effect, held by the British government. Thus drastic measures are set out in the Control of Pollution Act passed by Parliament in 1974 which was intended to activate the law to reduce all types of environmental pollution. However, many of the most important sections of the Act have not yet been brought into operation.

It is generally agreed that, in Britain as in most industrialised countries, river pollution is the most serious problem. We know how our fresh waters could be improved, and we have the methods to do so. Yet it is just those provisions which would most affect our rivers which are in abeyance, and this is because our economic record is so dismal and our growth so slow. Mr Denis Howell, on behalf of the Secretary of State for the Environment, confirmed this in *Hansard* on 17 February, when he informed Parliament that "Implementation of the remaining provisions [of the 1974 Act] has been delayed because of present constraints on public expenditure but will take place as soon as possible".

This lack of legislative progress is disappointing, but is it important? All the evidence suggests that, during recent years, our dirtiest rivers have continued to improve even without the force of the new law. Every year more species of fish return to the Thames, and we now have a report that there is a healthy population of three-spined sticklebacks in the River Clyde off Glasgow Green—the first instance of fish breeding in this area for over a hundred years. Even with their limited resources authorities with the will to succeed have found a way to improve the situation. To restore salmon and trout to the Thames and the Clyde will take time, and the expenditure of a great deal of money for more and better sewage treatment. Only industrial growth or a drastic reorganisation of our economic system can supply the funds. To try to enforce regulations for which money is not available is a recipe for chaos, not for a clean environment.

correspondence

Scottish science

SIR,—Martin Goldman's distaste for the idea of devolution in Scotland (17 March, page 208) should not let him mislead readers by saying that Scotland does well out of grant-giving bodies such as the Medical Research Council (MRC).

The MRC spends 8.6% of its budget in Scotland which has 9.7% of the UK population (*Hansard* 18 December 1975) and if the figure were based on the number of medical students or teaching staff it would be 17%.

I am told by those who advise the MRC that the reason the Scottish figure is low is that Scottish applications are rare, and that the reason for this is that the Scots believe that the clever people in London are more deserving of the money. The only cure for this affliction of the spirit is devolution or federalism.

Finally, Dr Goldman's view that devolution or federalism cannot work will be read with amusement in North America.

Yours faithfully,
D. N. M. HAMILTON

Nuclear irrationality

SIR,—My brief essay "Nuclear Power, Public Interest and the Profesisonal"[1] was essentially a plea for critical rationality (and the consequent anti-authoritarian approach) in the way society evaluates nuclear power. Two letters[2,3], present critical comments which I think are partly irrational.

Dr Grantham makes several misleading statements. One example is the comment on small reactors and "bomb-capacity commercial reactors" in relation to "a few microgrammes (of plutonium) can kill you". Another example is "the (nuclear) battle is one-sided. Pronuclear propagandists are paid: the opposition is not". Apart from pointing to the falsehood in the latter part of this statement, I emphasise that I do not look at the nuclear debate as a battle. My essay was an attempt to get at the facts and to emphasise the need for a rational debate on all "sides".

Dr Grantham has also chosen to disregard completely almost all my basic points. He states that "nuclear industry representatives seem to want to exclude biologists, environmentalists and the general public from the controversy", and "instead of trying to restrict the discussion to experts we should indeed extend it to everyone". In this connection I refer to two of my statements: "Probably no technological decision in the history of mankind has been the subject of so many detailed studies, so much open discussion and such broad participation", and "The scale and timing of the introduction of nuclear power is a major and complex decision. In a democratic society such decisions are not left to technological experts but to elected political officials".

Dr Grantham objects to what he calls my "suggested dichotomy: reasonable, rational and valid" versus "irrational, emotional and ethical". Again a quote from my essay is relevant: "Clearly, a number of irrational, emotional and ethical factors may be and should be of importance in a choice of power plants for the production of electricity".

On the role of scientists in public debate, Dr Anfinsen states that "anyone but the most naive petition-signer must understand that sponsors of socio-scientific news releases are, and always will be, selected on the basis of the fact that the general public tend to be influenced by lists of the names of 'dignitaries' ". This is precisely the basis for my criticism of petition signers using their titles when these are irrelevant to the matter. For example, a responsible *nuclear* physics professor will know if his personal background justifies him speaking on the *nuclear* energy question as a *nuclear* physicist (with a consequent intended and justified substantial impact on politicians and the public), or if he ought to speak as Mr J. Q. Public. Hence my plea that specialists should not mislead the public by carrying their specialist background as a flag in unrelated issues.

Incidentally, in referring to E. Rabinowitch (for whom I have great respect) as "a person concerning whose judgement and expertise in the area of science and public policy no one would quibble", Dr Anfinsen appears to embrace precisely the authoritarian approach which parts of my essay were directed against.

For Dr Anfinsen, as for myself, the question of a connection between nuclear power and potential nuclear wars is a key issue. It deserves not only the religious and emotional considerations put forward by Dr Anfinsen and the National Council of Churches of Christ in the USA, but also our utmost rational efforts to reduce the risk of such wars, with or without nuclear power. I fail to understand the rationality of distracting public attention from the all important issue of nuclear disarmament by expending substantial efforts on stopping the peaceful uses of nuclear power, which probably decrease rather than increase the risk of war.

Finally, I offer, upon Dr Grantham's request, my definition of rationality: to be rational and reasonable is to apply flexibly the control of our knowledge and our theories to our actions, so that we can perform the continuous trial and error process required for improving our adaptation to the environment by way of critical argumentation, thus reducing the need to subject our physical beings to those vagaries of nature and emotions which are harmful.

The place of facts in the world of human values should be set by the values, but facts cannot be changed by values.

Yours faithfully,
JAN M. DODERLEIN

Requests for reprints

SIR,—Would you publish an appeal to scientists throughout the world on a matter which is on the one hand extremely trivial but on the other could eliminate a nuisance. I refer to the request for reprints by fellow scientists. Besides the cost of mailing these reprints, it is time consuming to cut out addresses from post cards, glue them onto envelopes, decipher poorly written names and very often have to write the whole address by hand or typewriter. It would make life so much easier if requests in future carried a stick-on label as a few from considerate colleagues already do.

Yours faithfully,
F. ECKSTEIN

Formation of planetary atmospheres

from Robert Hutchinson

THE inner planets are usually considered as having formed by the accretion of solids at least part of which could release a volatile fraction when heated. Outgassing from hot interiors would then have led to the formation of atmospheres. To understand the development and evolution of a planet's atmosphere therefore, the bulk chemical composition of the primitive material from which the body was built must be established. This is not an easy task; the bulk composition of the best known planet, Earth, is still disputed today.

During the past 10 years, cosmochemists, largely led by Anders' group at Chicago, have found that many meteorites are composed of fractions each representing stability at a particular temperature/pressure condition. Heterogeneity in meteorites led to the idea of heterogeneous accretion of planets (Harris & Tozer *Nature* **215**, 1449; 1967; Turekian & Clark *Earth planet. Sci. Lett.* **6**, 346; 1969).

Essentially, the Earth is thought to have formed by growth of a small body composed of refractory Fe–Ni metal and/or Ca–Al–Ti–rich oxides and silicates. As it grew, lower temperature Mg–Fe silicates were added until, lastly, accretion ceased with the addition of a hydrated, low temperature veneer. Heating of the veneer released water for our oceans and gases for our primitive atmosphere. Like many theories in planetary science, heterogeneous accretion is not without its critics. And the largely qualitative treatments of the 1960s are now being quantified.

It is against this background that the paper by Rasool and Le Sergeant in this issue of *Nature* should be viewed (page 822). The Viking landers obtained an estimate of the chemical composition of the martian atmosphere, so there is now reliable information on the atmospheres of two inner planets which must be accommodated in any model of atmospheric development. Using the simplest treatment, Rasool and Le Sergeant assume the terrestrial and martian atmospheres to be essentially closed systems. They begin by looking at the better known Earth and attempting to find a suitable source material for the volatiles. Carbon- and water-rich carbonaceous chondrite meteorite is rejected because the Earth's atmosphere has too much ^{20}Ne and other heavier inert gases relative to C (and H). Instead, the volatile-poor LL group of ordinary chondrites is chosen as it gives a better match, especially for the inert gases. It is argued that a 116-km thick veneer of LL group chondrite could have been outgassed to produce oceans and atmosphere.

When a similar model is applied to Mars it is found that the quantity of LL group chondrite required to produce the atmospheric ^{36}Ar content would produce more N, C and H than are observed in the atmosphere. The amounts of ^{84}Kr and ^{132}Xe agree with the ^{36}Ar abundance. Rasool and Le Sergeant go on to argue that if the N, C and H are not in the atmosphere, they may be in the regolith or on the martian surface; for example, H may be present as polar water ice up to 40-m thick. Near surface volatiles could be temporarily released to form an atmosphere of CO_2 and H_2O with surface pressure of 400 mbar.

Finally, the high ^{40}Ar content of the martian atmosphere is considered in the light of the low upper limit (0.25%) for K in the martian surface (^{40}K is the radioactive parent of ^{40}Ar). Because the martian surface is apparently not as enriched in K as is terrestrial continental crust (but compare oceanic tholeitic basalt, with less than 0.1%K) Rasool and Le Sergeant argue that ^{40}Ar on Mars has come from a greater thickness of material than the other volatiles. It is also implied that K has not been concentrated upwards on Mars due to lack of complete melting in this planet.

It is likely that Rasool and Le Sergeant's paper will prove to be controversial. A probable line of attack is that terrestrial O isotopic ratios define a chemical fractionation line enriched in ^{16}O relative to LL group (and other) ordinary chondrites (Clayton *et al. Earth planet. Sci. Lett.* **30**, 10; 1976). This argues against an LL group origin for terrestrial volatiles, but for the foreseeable future, martian O isotopic ratios will remain unknown. ☐

Redox potentials of iron-sulphur clusters

from A. J. Thomson

THE non-haem iron proteins consisting of clusters of iron and sulphur are known to be involved in a wide range of biological processes from steroid hydroxylation and CO_2 and N_2 fixation to oxidative phosphorylation and photosynthesis. They have been isolated from obligate anaerobic bacteria, aerobic bacteria, algae, plants and all animals so far investigated. Their single most important function is the catalysis of oxidation/reduction reactions and the transport of electrons to reaction centres.

For this reason the range of redox potentials exhibited by the Fe-S clusters is of great interest. It is now emerging that proteins containing a common structural Fe-S centre can have widely differing redox potentials. For example the high potential iron protein (HIPIP) from *Chromatium vinosum* and the bacterial ferredoxin from *Peptococcus aerogenes* are close structural relatives. The former contains a single cubane-type four-iron sulphur cluster $[FeS_4\text{-(S–Cys)}_4]$ whereas the latter possesses a pair of these units. However, functionally they are very different. HIPIP in the oxidised form gives an EPR signal which is abolished on reduction, and the mid-point potential of this process is +340 mV. By comparison the bacterial ferredoxin exhibits a one-electron reduction also but to give an EPR signal in the reduced state only and with a mid-point potential of about −400 mV. These puzzling observations were neatly explained by a hypothesis due to Carter *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **69**, 3526; 1972) which suggested that the clusters in the two proteins were undergoing reversible redox changes between two different oxidation states, in the following manner

$$\underset{\text{HIPIP oxidised}}{\overset{\overset{C^{-}}{\text{(paramagnetic)}}}{[Fe_4S_4(S\text{-}Cys)_4]^{-}}} \rightleftharpoons \underset{\substack{\text{HIPIP reduced}\\ \text{Ferredoxin oxidised}}}{\overset{\overset{C^{2-}}{\text{(diamagnetic)}}}{[Fe_4S_4(S\text{-}Cys)_4]^{2-}}}$$

$$\rightleftharpoons \underset{\text{Ferredoxin reduced}}{\overset{\overset{C^{3-}}{\text{(paramagnetic)}}}{[Fe_4S_4(S\text{-}Cys)_4]^{3-}}}$$

It is not therefore to be expected that the two proteins will show similar mid-point potentials or EPR characteristics. The three-state hypothesis was quickly given confirmation by Cammack (*Biochem. biophys. Res. Commun.* **54**, 548; 1973) who showed that HIPIP could be further reduced by dithionite to the C^{3-} state termed the super-reduced form of HIPIP in the presence of more than 70% by volume of dimethylsulphoxide which serves to unfold the tertiary structure of the protein. This demonstrated that the protein environment prevents further reduction or oxidation of the cluster, ensuring that only single electron transfers are carried out by the protein. Subsequently it was shown that in the presence of ferricyanide the bacterial ferredoxins can be super-oxidised to produce an EPR signal similar to that of oxidised HIPIP (Sweeney *et al. Biochem. biophys. Res. Commun.* **59**, 188; 1974).

Although crystal structures are available for both HIPIP and the bacterial ferredoxin from *Peptococcus aerogenes* it is not clear what features of the protein environment control the redox potential of the cluster. In the past eighteen months two new examples of iron–sulphur proteins have been investigated which show that the control by the protein environment is remarkable. The first example is a protein from *Azotobacter vinelandii*, FdI, which has been obtained in crystalline form and shown to contain two four-iron clusters. (Sweeney *et al. J. biol. Chem.* **250**, 7842; 1975). As isolated the protein shows an EPR signal very similar to that from super-oxidised bacterial ferredoxins. The signal disappears on photoreduction with spinach chloroplast fragments with a mid-point potential of −420 mV. Apparently the cluster is undergoing the C^{-} to C^{2-} reduction with a mid-point potential ~ 760 mV below that of the HIPIP cluster. Furthermore, oxidation of FdI with ferricyanide produces an EPR signal on uptake of one electron but with a mid-point potential of +350 mV. It is concluded that *A. vinelandii* FdI is the first example of an iron–sulphur protein which contains two clusters functioning between the same pair of oxidation states as HIPIP but with mid-point potentials 760 mV apart.

The second, and more recent, example is seen in three ferredoxins (FdI, FdI′ and FdII) extracted from the sulphate reducing bacterium, *Desulphovibrio gigas* (Cammack *et al. Biochim. biophys. Acta* **490**, 311; 1977). With molecular weights of 18,000, 18,000 and 24,000, respectively, the three proteins appear to be oligomers of a basic unit of molecular weight 6,000 containing one four-iron cluster. By monitoring the appearance and disappearance of the C^{-} and C^{3-} states with low temperature EPR measurements the mid-point potentials of clusters within the three proteins have been determined. Their values are summarised below.

	FdI	FdI′	FdII
$C^{-} \updownarrow C^{2-}$	$\updownarrow$ −50 mV	$\updownarrow$ −30 mV	$\updownarrow$ −130 mV
$C^{2-} \updownarrow C^{3-}$	$\updownarrow$ −455 mV	$\updownarrow$ −130 mV	$\updownarrow$ −437 mV

The three ferredoxins differ markedly in the intensities of the various EPR signals leading to the conclusion that FdI undergoes reduction between C^{2-} and C^{3-} states, FdII between C^{-} and C^{2-} states and FdI′ can be produced in both C^{-} and C^{3-} states. There is no evidence that a single cluster can reversibly change between all three oxidation states. A more plausible interpretation is thought to be that in some subunits of the protein the four-iron centre undergoes the C^{-}/C^{2-} transition whereas in other subunits of the same protein the C^{2-}/C^{3-} transition can take place.

Although the three-state hypothesis undoubtedly correctly assigns the oxidation states to the clusters, the very property it sought to explain—the difference between the redox potentials of HIPIP and bacterial ferredoxins—requires more subtle interpretations in the light of these new results. Several mechanisms for the control of the cluster redox state by the polypeptide have been discussed. It has been shown that the cluster geometries in oxidised and reduced *Chromatium* HIPIP are significantly different. This led to the suggestion that the size and shape of the cluster-binding cavity might be designed to favour one oxidation state. (Carter *et al. J. biol. Chem.* **249**, 6339; 1974). Alternatively, a given oxidation state could be stabilised appreciably by the formation of hydrogen bands between the cluster and the protein. Carter and coworkers (*op. cit.*) have identified NH+ . . . S hydrogen bonds in their crystal structure determination of HIPIP. Finally, it may be significant that the newly discovered examples are all of proteins containing more than one cluster. It could be, as Sweeney, Rabinowitz and Yoch suggest, that inter-cluster interaction is strong enough to modify mid-point potentials. The study of water-soluble model compounds could provide some interesting comparative data.

New light on old mesons

from Peter J. Litchfield

The excitement generated in the high energy physics community by the discovery of the ψ/J mesons and the emergence of the 'new physics' of charm has tended to overshadow developments in the field of conventional meson spectroscopy. However, new results from a partial wave analysis of the reaction $\bar{p}p \rightarrow \pi^{+}\pi^{-}$, just published by a Queen Mary College, Daresbury Laboratory and Rutherford collaboration (*Phys. Lett.* **67B**, 117; 1977), have shown that the old-fashioned charmless physics still has some surprises in store. The groups have determined the spins and parities of three resonances with masses approaching those of the ψ mesons; by some way the heaviest conventional mesons with well-established quantum numbers. The states seem to lie on a daughter Regge trajectory with unexpected properties which, if confirmed, could cause a major upset in our theoretical ideas. The minimum disruption would require a modification of the predictions of Regge models at high energies and momentum transfers. It could, on the other hand, be possible that these resonances are manifestations of four quark 'exotic' states and signal the opening of a whole new branch of particle physics.

The search for high mass resonances is complicated by their small branching fractions into any given final state and their large widths which result in strong overlapping of adjacent resonances. The only satisfactory experimental access to them is by way of formation experiments in which measurements of the differential cross sections and polarisation parameters are made as a function of centre-of-mass energy. This enables the reaction to be decomposed into its constituent partial waves and thus enables resonances in a given spin parity (J^{P}) state to be observed. The new discoveries have been made possible by high statistics measurements of the differential cross sections and polarisations for the reaction $\bar{p}p \rightarrow \pi^{+}\pi^{-}$ in the centre-of-mass energy range 2,020 to 2,580 MeV made at CERN by the QMC, Daresbury and Rutherford groups (together with physicists from Liverpool for the differential cross section data). They are the first measurements which are sufficiently precise to enable a definitive partial wave analysis to be performed in $\bar{p}p$ annihilations. The analysis has revealed the presence of resonances at masses of 2,150, 2,310 and 2,480 MeV/c^2 with spin parities 3^-, 4^+ and 5^- respectively. The two lower mass states have been observed before as bumps in the total and elastic cross sections but this is the first determination of their quantum numbers.

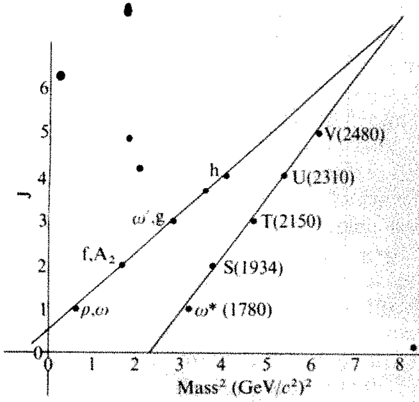
One method of classifying resonance states is to plot them on a graph of spin *versus* mass squared where states are found to lie on straight line trajectories known as Regge trajectories. Figure 1 shows this plot for the dominant mesons found in production experiments, the ρ, ω, f, A_2 . . ., together with the three new states, another pp resonance found at a lower mass (the S(1934)) and a 1^- state recently reported from an e^+e^- annihilation experiment at Orsay. There are clearly two separate trajectories, one for the dominant mesons in production and one for the dominant mesons formed in pp annihilation experiments.

The plot yields two surprises. First, the lower trajectory (called a daughter trajectory) is not parallel to the leading trajectory. Regge phenomenology has always assumed that trajectories are linear and parallel. Although very closely linear, the slope of the daughter trajectory is considerably greater than that of the leading trajectory. This could have important consequences if the trend continues since at higher energies and momentum transfers the new trajectory would dominate the ρ trajectory which is the only one usually retained in theoretical calculations.

Second, it is puzzling that the dominant resonances in $\bar{p}p \rightarrow \pi^+\pi^-$ are not on the leading trajectory as is the case in all other known reactions. An observation by this same group from their data on $\bar{p}p$ elastic scattering taken as a by-product of this experiment (*Nucl. Phys.* **B113**, 1; 1976), indicates a possible explanation. In that reaction they find that there is a characteristic maximum radius of interaction of approximately 1.5 fm. If this is also true in the $\pi^+\pi^-$ reaction and we assume a simple impact parameter model where the angular momentum is given by the radius of interaction times the centre-of-mass momentum, then the maximum angular momenta accessible at the resonance masses are those on the daughter trajectory. Resonances on the leading trajectory could not be formed.

An alternative but much more speculative explanation is that the new states are qualitatively different from those on the ρ trajectory, that is, they are made up of two quarks and two antiquarks rather than only one of each. Speculation on the existence of such exotic states has been rife in the theoretical world for several years and there has recently been rather weak evidence that such states may be formed in e^+e^- annihilations around 4.03 GeV (see *Nature* **266**, 301; 1977) and in $\bar{p}p$ annihilations at 12 GeV/c (*Phys. Lett.* **66B**, 185; 1976). Theoretically pp formation experiments would be the ideal place to observe such states since an interaction in which a quark–antiquark pair was annihilated from the three quarks in the proton and three antiquarks in the antiproton would leave a state consisting of just two quarks and two antiquarks.

$\bar{p}p$ annihilations have long been advocated as the place to search for high mass mesons. It is only now after many years of effort that data of sufficient quality to realise these expectations have been obtained. Many questions remain. Does the new trajectory continue linearly and overtake the leading trajectory, or does it eventually flatten out? Data at higher masses could give the answer. Better data on the K^+K^- channel (also measured in this experiment but with much lower statistics) or on the 3π channel would give access to states not available in the $\pi\pi$ channel. Do they have similar properties to those described here? Does the $\bar{p}$ just have a propensity to interact at a range of about 1.5 fm or are these states truly exotic? The interest of high energy physicists in conventional meson spectroscopy has been reawakened and already new experiments to investigate the $\bar{p}p$ system have been proposed. ☐



Picornavirus RNAs are interesting . . . and unique

from T. J. R. Harris

Apart from satellite tobacco necrosis virus RNA, picornavirus RNA molecules provide the only well established exception to the 'capping' rule. These messenger RNA molecules lack the $m^7G(5')ppp(5')X$. . . that is characteristic of so many virus specific and cellular mRNAs from eukaryotic cells (see *Nature*, **263**, 188; 1976).

Experiments with polynucleotide kinase, an enzyme from T4-infected *E. coli* which adds ^{32}P from $\gamma^{32}P$ ATP to 5′ OH groups, initially suggested that the 5′ end of poliovirus RNA was pAp. The possible endonuclease contamination of the kinase preparation used made this experiment rather unsatisfactory and the discovery of a 5′ cap on various virus mRNA molecules (particularly those of other animal viruses which have a genome that is a messenger RNA, Sindbis virus for example) led to a re-examination of the 5′ terminus of poliovirus RNA, as well as that of other picornavirus RNAs.

Several papers have been published in the past year reporting the outcome of these new investigations. It is clear that the 5′ terminus of 35S poliovirus-specific mRNA isolated from the polyribosomes of infected cells is pUp. On the other hand neither a nucleoside diphosphate nor a capping group was found on the RNA extracted from virus particles. As the genome RNA presumably acts as a messenger RNA to initiate infection, this was a distinctly puzzling result. It is not surprising that an answer to the apparent paradox was soon forthcoming. Wimmer's group (Lee *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 59; 1977) and Baltimore and his co-workers (*Proc. natn. Acad. Sci. U.S.A.* **74**, 961; 1977) now have evidence that there is a small protein (molecular weight around 7,000) covalently linked to the 5′-nucleoside diphosphate. As well as explaining the difficulty of finding a 5′ end, the presence of the protein on nascent RNA chains in the replicative intermediate has led both groups to speculate on a role for the protein in RNA synthesis, although some function in virus particle morphogenesis is not discounted.

Another interesting structural feature of picornavirus RNAs, unique among animal virus RNAs, is provided by the RNA of viruses belonging to the cardiovirus sub-group. Like some plant virus RNAs such as tobacco mosaic virus (TMV) and turnip yellow mosaic virus (TYMV), cardiovirus RNAs can be aminoacylated *in vitro*; mengovirus RNA with histidine and encephalomyocarditis virus (EMCV) with serine. The part of the RNA molecule which is aminoacylated has not yet been determined. In contrast the RNA of poliovirus and foot and mouth disease virus (FMDV), both members of different picornavirus sub-groups, cannot be aminoacylated.

Although not containing a capped 5′-end, RNA molecules from representatives of all the picornavirus sub-groups possess the 3′-terminal poly(A) characteristic of a number of other virus mRNAs. In addition to poly(A) the RNA of the cardioviruses contains a poly(rC) tract. Until recently the location of this homopolymeric region in the RNA was not known. Two papers published at the end of last year now indicate that the poly(C) is very near the 5′-end of both EMCV RNA and FMDV RNA and there is the possibility that the sequence is 5′-terminal.

It will be interesting to determine the structural basis of these differences in the RNAs of the various picornaviruses and to discover their functional significance in the replication of the viruses. ☐

Magnetostratigraphic pitfalls

from George Kukla and J. D. A. Zijderveld

CONTROVERSY is growing over the existence of young excursions of the Earth's magnetic field such as the Gothenburg event (Morner & Lanser *Nature* **251**, 408; 1974). Are these features real? Are they true records of magnetic anomalies? Do they influence climate (Fairbridge *Nature* **265**, 431; 1977)? Or are they merely a product of overlooked natural or artificial strata deformations (Thompson & Berglund *Nature* **263**, 490; 1976; Opdyke *Earth planet. Sci. Lett.* **29**, 238; 1976)? The recently reported detailed study of Koobi Fora formation in Kenya (Hillhouse *et al. Nature* **265**, 411; 1976) shows that the magnetic reversal stratigraphy of Pre-Brunhes formation is not without difficulties either. With all these problems, can palaeomagnetic 'magic' still be taken seriously?

The participants* of the steering committee session of Project 128 of the International Geological Correlation Program concluded at a meeting in Paris, last September, that it can. The project, a joint venture of UNESCO and of the International Union of Geological Sciences was organised to foster intercorrelation of magnetostratigraphic zones with regional stratigraphic systems and radiometrically dated levels. It is a continuation of former IGCP Project PA.70.17 (see Kukla & Nakagawa *Geology* **3**, 704; 1975).

But there are complicating features to which increased attention should be paid. The most important of these are the presence of post-depositional magnetostratigraphic overprints, natural deformation of the strata under investigation, deformation caused by the coring and sampling devices and the continuity and sedimentation rates of the deposits.

Finding the remanent magnetisation of a sample is only one of three equally important procedures in magnetostratigraphy. The other two are—establishing the original position of the sample at the time of deposition, and the correlation of recognised magnetozones with the standard palaeomagnetic time scale.

Unchanged position of studied layers

The remanent vector of samples can only be related to the direction of the Earth's magnetic field if the original orientation of the layer is preserved or the amount of later deformation known. Most researchers assume that their oriented samples precisely represent the layer at the time of deposition and dedicate lamentably little effort to testing whether this is really the case. In studies of secular magnetic variation and of magnetic anomalies, this is a critical limiting factor. Unfortunately, the occurrence of local deformations due to slumping, crust loading, mudflows, and so on, even in generally well stratified horizontal beds is common. Such features can be detected in exposures (Verosub *Science* **190**, 48; 1975) but easily overlooked in cores. The coring operation in unconsolidated sediments further increases the incidence of unrecognised deformations. Arching, twisting, and 'sucking in' of sediment frequently affects the cores as can be observed on samples from laminated deposits. Also non-vertical penetration of the corer and systematic inclination errors affect the reliability of data. It is difficult to detect a deformation of homogeneous unstratified layers, although X-ray screening may prove helpful.

Plastic deformations may frequently occur at lithologic boundaries such as sand–clay interfaces. The core may also be deformed in handling, cutting in segments, and in storage. Freezing of cores as practiced by some palynological laboratories can produce large ice crystals which can damage the core structure. In this context, it looks suspicious when all the magnetic excursions reported in the upper 30 m of Biwa Lake core (Yaskawa *et al. J. Geomag. Geoelectr.* **25**, 447; 1973) come from the top or bottom parts of defrozen core segments.

We would not like to imply of course that all local excursions of the Earth's magnetic field reported from cores are misinterpreted records of deformed layers. However, it is only fair to state that at present, no firm evidence exists to the contrary.

Only results reproduced in parallel sections should be taken as indicative of the behaviour of the Earth's magnetic field (Creer *et al. Earth planet. Sci. Lett.* **31**, 37; 1976). A layer with anomalous, but internally inconsistent magnetic record should be first checked in detail for anomalous sediment structure, sliced and X-rayed for example, before any attempt is made to interpret it as a record of past magnetic field. Duplicate or triplicate sampling of a core should be attempted whenever the diameter is sufficiently large to allow such a procedure. Performance of coring devices should be tested on recent sediments of similar consistency and size distribution as the studied layers.

Recovery of original magnetic record

The Koobi Fora study (Hillhouse *et al. op. cit.*) is an excellent example of problems surrounding the recovery of original remanent magnetisation. No universal palaeomagnetic technique is available at present that can guarantee a complete removal of post-depositional magnetic overprint and unambiguous identification of depositional polarity. This could become a serious problem in land-based deposits exposed to prolonged weathering and to the action of groundwater. Sediments deposited during intervals of reversed polarity may acquire fully normal remanent magnetisation during subsequent weathering episodes. Normal remanence of land-based weathered strata does not exclude their formation at the time of reversed polarity. Similar problems caused by remagnetisation were also indicated at the seafloor (Watkins *et al. Earth planet. Sci. Lett.* **24**, 113; 1974). Thus, the polarity corresponding to the time of

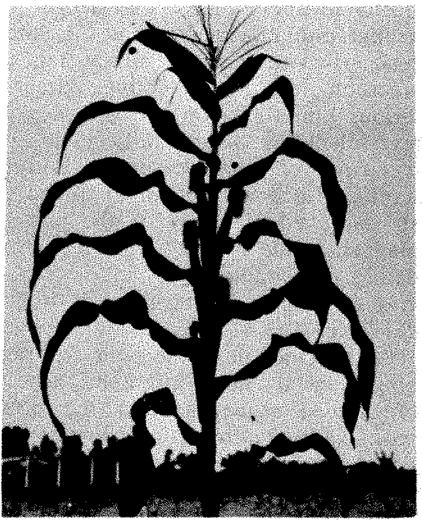
Maize in Yugoslavia

from D. O. Hall



A QUARTER of Yugoslavia's arable land is planted to maize, which vies with wheat as the single most important crop in Yugoslavia. A visit to the Maize Research Institute outside Belgrade proved an eye opener as to how a State Research Institute can be entirely self-supporting from the commercial sale of its products and expertise and at the same time support an active and directed basic research programme which complements its commercial and plant breeding sections. As a novice in this area I may have been over-impressed by the single-mindedness and enthusiasm of the workers at this Research Institute, applied to all stages of the production of a single crop—from research on seed production and gene banks to the extension services on the farm and the sale of seed and expertise (at home and abroad). The increasing interest in growing maize in the UK and Europe both for forage and grain has highlighted the versatility of this plant. It can be grown in a wide range of climates—all that is needed is to find a variety which suits the particular area and the purpose for which it is to be grown.

The Maize Research Institute at Zemun-Polje, about 15 km outside Belgrade, is situated on about 300 hectares of productive land, which is unfortunately now being encroached on by urban and industrial development. Modern well equipped laboratories have a pleasant working atmosphere in extensive fields around a central complex. The Institute employs about 250 people, a quarter of whom have university degrees, and is organised into three different divisions, a science division, an extension service, and an administrative and commercial affairs section. The extension service, which is involved in the controlled production of seed on large cooperative farms and which advises experimental farms, is the crux of the Institute's success. Nearly all the Institute's finance comes from royalties on the sale of its hybrid seeds, both in Yugoslavia and abroad. Nearly a half of its income is from abroad and it has close commercial and research links with more than 20 different countries. Seeds are produced on about 20,000 hectares of good seed-producing land with a suitable climate.

The variability of climate in Yugoslavia from Mediterranean to Continental, its varied geography, and centuries of maize growing, have resulted in a unique maize gene bank. It is claimed that the Maize Institute has more than 100,000 different genetic combinations available for selection of new maize types. The storage of this gene bank is a major part of the Institute's service, since it provides a source of material not only for its own breeding programme but also for research work and hybrid seed production abroad. Yugoslavia seems to have been fortuitously placed in a favourable position for restocking the world's depleted gene banks, especially in North America where the widescale use of hybrid species has resulted in neglect of other varieties selected over the centuries. The Maize Research Institute is making the most of this advantage. Its sales of hybrid seed abroad and patented rights of seed production extend to 18 countries and these hybrids are now grown on over 1.5 million hectares abroad—not bad going for an Institute that only started to specialise in 1959.

Maize in Yugoslavia is mainly fed to cattle. More than 87% of the corn is converted into meat and Yugoslavia is a meat exporter. However fluctuations in the price of meat are resulting in a reassessment of the use of maize and new developments from the United States such as the production of glucose/fructose syrup and the utilisation of the whole maize plant for other types of product are being actively investigated. The potential for greater use of maize seems to be there. Over the past seven years the average yield of maize in Yugoslavia has doubled as a result of the use of the Maize Institute's hybrids which are now grown on two thirds of the total land area cropped to maize. They claim now that they have more than 75 new hybrids which will yield about 10 tonnes of grain per hectare as opposed to the average in Yugoslavia of 4 tonnes per hectare.

Research at the Institute is divided between four sections. Breeding and Genetics naturally employs the largest number of scientists, many of whom have been trained in North America. Research in the Physiology, Biochemistry and Technology Section takes several basic approaches which may have long term application to genetics and maize production. Low temperature growth in maize is being studied in the hope of extending the growing season by earlier planting and of understanding the physiology of low temperature adaptation. Developmental physiology and adaptation to the various climates found in Yugoslavia are also under investigation. Protein biosynthesis is being studied with the aim of increasing the lysine and tryptophan content of the plant. Biophysical assays which can be used for selection during breeding programmes are also being developed. The third section, Maize Protection, deals with fungal and bacterial diseases, insect attack and weed problems. The fourth, Agronomy, is involved in the techniques of maize cultivation. The integration of basic research and seed production and commercial exploitation seems in the case of this Institute to have been particularly successful.

---

deposition is to be considered an interpreted property of unequal accuracy, dependent on lithology, intensity of remanence, post-depositional history of the layer, the demagnetisation programme and the instruments used.

In these circumstances, the validity of magnetostratigraphic zonation of sedimentary rocks is only proved by reproduction of the results in sequences involving different lithologies, depositional environments and sedimentation rates. Results of highest confidence are those obtained on stratigraphic successions of effusive volcanic rocks where the danger of remagnetisation is minimal. Magnetostratigraphers are urged to duplicate sampling in parallel sections and in parallel cores wherever possible. Further effort is also needed in studies of rock magnetism dedicated to recognition of original remanence from overprint and to improvement of our understanding of processes through which the remanence of sediments is acquired and destroyed.

Correlation of magnetozones with palaeomagnetic chronology

Magnetostratigraphy is not a dating technique. It only provides globally synchronous correlation planes, whose identification is possible by comparisons with other stratigraphic or radiometric data.

Local polarity zones represent valuable stratigraphic units independent of palaeomagnetic chronology which should be locally labelled and their boundaries clearly identified with respect to lithologic or biostratigraphic zonation. They could, but need not be correlated with the standard palaeomagnetic time scale. The time represented by the deposit is critical in the correlation. Is the deposit continuous? If so, what is the sedimentation rate? Does the thickness of the magnetostratigraphic unit fit the length of palaeomagnetic interval with which it is correlated? Does the reversal occur in a continuously deposited sequence? Or is it only an unrecognised hiatus? Many otherwise excellent magnetostratigraphic studies paid only marginal attention to the continuity and homogeneity of the sedimentary record. This resulted in serious miscorrelations, such as mistaking events for epochs (see Kukla & Nakagawa *op. cit.*).

The palaeomagnetic chronology scale is not a stratigraphic system since it was constructed from radiometrically dated samples of known polarity mostly without any knowledge of stratigraphic relations among the dated horizons. Under these circumstances, precision of K-Ar dating imposes serious limitations on the accuracy of reversal dating. Uncertainty about the true age of most reversals is substantial. Concentrated effort aimed at an improved accuracy of the palaeomagnetic scale by multiple radiometric dating of suitable layers in the stratigraphic vicinity of reversals is highly desirable.

As it stands now, the poor coverage of geological and stratigraphic aspects of studied sequences and the often insufficient removal of post-depositional overprint seem to be the principal weaknesses of magnetostratigraphy correlation. Most of the existing problems could be avoided or at least substantially reduced if repetitive sampling of parallel sections becomes a regular practice. ☐

Plants and animals interact

by Mary Lindley

An international symposium on Biochemical Aspects of Plant and Animal Coevolution was held by the Phytochemical Society of Europe in Reading on 4–6 April, 1977. The proceedings will be published by Academic Press.

CATALOGUERS of the chemical compounds found in plants are being stimulated to new thoughts by ecologists. They are looking for an explanation of how the compounds serve the plants and affect their interactions with animals. The members of the Phytochemical Society of Europe are closely involved and if evolutionary trends are slow to emerge, there seems to be no shortage of enthusiasm and ideas.

Volatile compounds are proving to be important in the pollination of orchids of the genus *Ophrys*, which resemble female insects. Male bees are induced to effect pollination while trying to copulate with the flowers, and some of the stimuli are odoriferous, as G. Bergström (University of Gothenborg) explained. He does not discount visual and tactile stimuli, but it seems that the morphology of the flower plays a small part in the process of attraction. It is not yet known whether the various volatile compounds identified in the flowers enable them to mimic the sexual attractions of the bees—more structures have to be determined, particularly of cyclic terpenes.

The bees gain no nutritional benefit from *Ophrys*, but most of the interactions discussed involved the consumption of plants by animals, chiefly insects. Discussing the role of nitrogen in such interactions, S. McNeill (Imperial College Field Station, Silwood Park) reviewed evidence of a correlation between the abundance of insects on plants and the amount of nitrogen available as protein and amino acids. For example, the most numerous populations of insects on the grass *Holcus mollis* coincide with the peaks of nitrogen during spring and autumn. At the best of times the amount of nitrogen in plants is low compared with that of animals, and insects use various strategies to minimise the disadvantage. When it is lowest they may simply consume more material or move to a more nutritious plant or part of a plant. They might be able to modify the local physiology of the plant, for example by causing proteolysis, or they might turn to occasional predation on other animals as a source of nutrition.

The migratory and desert locusts (*Locusta migratoria* and *Schistocerca gregaria*) select the plants to give them the necessary nutrients through the effects of phagostimulants and deterrents. R. F. Chapman (Centre for Overseas Pest Research, London) explained that sugars, for example, stimulate locusts to feed, while such compounds as alkaloids deter them. It seems that for a hungry locust the choice between different plants is determined by the presence of deterrents, while the size of the meal is more likely to be determined by the phagostimulants in the chosen host. Chapman suggested that two events in the evolution of plants particularly influenced the evolution of the locusts and their grasshopper relatives, the Acrididae. The first flourishing of the Acrididae seems to have coincided with the development of the flowering plants and the decline in the occurrence of condensed tannins, which are powerful deterrents. Later, with the coming of the grasses, the Acrididae could diversify again. Such examples, however, are unlikely to have been common in the evolution of insects, which Chapman stressed, has not been due on the whole to the influence of plant chemistry.

E. A. Bell (King's College, London) said that it has been a tenet of faith for him that plants make so many secondary compounds because they cannot run away from their enemies. The toxins in seeds include lectins, cyanogens, alkaloids and uncommon amino acids such as canavanine, but they are not all equally toxic to all animals. D. H. Janzen (University of Pennsylvania, Philadelphia) pointed out that the protection of seeds often needs to be more effective than that of leaves. Seeds contain a store of nutrients that makes them very attractive to predators unless unpleasant toxins are also present. To study the response of insects to various seed components, Janzen has been using synthetic seeds made from crushed seeds of the animal's host plant and incorporating into them toxins from other plant species.

On the basis of field tests, T. J. Mabry (University of Texas, Austin) believes that sesquiterpene lactones serve primarily as a bitter principle, discouraging animals from feeding. Deer and rabbits, for example, will not feed on plants containing such toxins, which occur most abundantly in the Compositae.

Participants did not all accept the view that secondary plant compounds always have a defensive role. D. A. Jones (University of Hull) feels that there is no absolute advantage in cyanogenesis, by which a cyanogen and the appropriate enzyme release hydrogen cyanide when the plant is crushed. His evidence was obtained with the polymorphic species *Lotus corniculatus* (bird's foot trefoil), which contains both cyanogenic and acyanogenic plants. Jones has found that on a cliff the greater tolerance of salt spray by acyanogenic plants is balanced by the higher potential rate of reproduction of cyanogenic plants. In close proximity, in a hollow and on a mound, selective grazing by snails gives an advantage to cyanogenic plants. Clearly the situation is not as simple as it once seemed.

The traditional idea of a battle between insects and plants is also too simple according to H. F. van Emden (University of Reading). Drawing on his experience with aphids, he presented an alternative viewpoint. Insects such as aphids, which are restricted in their selection of host plants, might gain an advantage if the secondary compounds in the plants are primarily a defence against vertebrate predators. One benefit would be that both the insects and their food would be protected. □

Materials science and engineering

from Robert W. Cahn

"A GENERAL survey or reconsideration" is one of the meanings attached by the Shorter Oxford English Dictionary to the word *Review*. That usage dates from 1604, when modern science was in its birth throes. The natural philosophers of that time knew and corresponded with each other, and that curse and blessing of our day, the scientific journal, was as yet unknown and unnecessary. Today, the general survey or reconsideration is as essential to the working scientist as the Good Food Guide to the serious gourmet.

A review, of course, tells a scientist in a nutshell what the current state of knowledge is in a field, with extra emphasis on recent facts and insights. Who ever heard of a survey of ignorance? Yet that is what the editor-in-chief of the journal *Materials Science and Engineering*, together with his Advisory Board, set out to provide to mark the tenth anniversary of the journal's publication. The 264 pages of volume 25, dated September 1976, are made up of 35 short essays devoted to "what we do not know about" a range of subjects which fall within the scope of the journal. The tacit objective seems to be to guide the research worker who is contemplating a change of field, or of emphasis within a field, into fruitful problems. The editor invited a number of specialists all over the world to map the gaps and chasms in their knowledge. The result is unconventional, variable and useful.

One contributor complains: "Throughout my professional life I tried to teach my students, when they were writing their first paper, not to elaborate too much what they didn't know. Of that, I told them, the future readers know enough themselves." However, the wise choice of expert contributors renders this review of ignorance acceptable and indeed useful. It is necessary to know a great deal before the gaps in that knowledge can be a source of wisdom. Nobody attempted to restrict himself to a survey of gaps: all, with greater or lesser terseness, first surveyed what is known. As another contributor expressed it—"I take it that we are asking: What principles governing . . . are generally agreed by the scientific community? What principles are controversial? What areas are unknown to the extent that no principles have been formulated?" This contributor achieved something very rare and indeed paradoxical in a scientific review: he included not a single reference to published work, but filled his own prescription in a discursive way, emphasising the important points without documentation. The essay — L. M. Brown's on the Deformation of 2-phase Alloys—is a thorough going success. This approach can be followed successfully only with a widely familiar topic; one which is less familiar may need plenty of documentation, and yet effectively pinpoint the crucial areas of ignorance; D. A. Vermilyea's essay on Corrosion is a case in point.

Some reviews are highly theoretical and can only be followed by a reader who is already highly expert (for instance, H. E. Cook on Continuous Transformations; M. Wuttig and T. Suzuki on the Martensite Transformation); others are severely practical, addressed to specific industrial objectives (A. G. Chynoweth on Fiber Lightguides for Optical Communications; M. C. Flemings and others on Rheocasting; J. A. Manson on Modification of Concretes with Polymers). Most cover their subjects in breadth, some (N. Brown on The Effects of Gaseous Environments on Polymers; Flemings on Rheocasting) describe only their own work and the problems uncovered thereby, justifiably since they opened up new fields. One particularly illuminating survey, V. F. Zackay's on Thermomechanical Processing, is not so much concerned with gaps in scientific understanding as with the problems of finding a development strategy which will increase the industrial acceptability of the complex form of processing with which it deals. Altogether, the volume is an intriguing study in styles. In general, the broader the author's range of vision, the clearer his presentation. One might have expected that when subject to such severe constraints on the number of words, the narrow specialist would have fared better, but indeed the general principle remains true that one sees the wood better from a helicopter than from the jungle trail.

The Editor does disclaim any attempt to cover the whole spectrum of materials science and engineering, but it is nevertheless true that coverage is lopsided. Nearly 80% of the reviews deal with metals and alloys, and within that category, there is heavy emphasis on the admittedly crucial topic of phase transformations.

It is nevertheless disappointing that only two essays deal with polymers (and one of these only does so tangentially), one with ceramics, and one with oxide glasses (again tangentially). There is no attempt to shirk topics in which understanding is unsatisfactory (E. Rabinowicz has plenty of ignorance to report on Wear, and does so without obfuscation), but no broad topic such as Materials in Biomedical Engineering is included.

In spite of the inevitable limitations and the uneven quality of the reviews, this volume deserves to be widely purchased by junior research workers particularly (the price is set low to enable them to do so). They should use it in conjunction with another compendium of useful short reviews, *Annual Reviews of Materials Science*, to gain a first-class overview of the direction in which the discipline is currently heading. □

A hundred years ago

A VERY extensive Etruscan necropolis has been discovered at Montelparo, near Ascoli-Piceno (Umbria). An enormous quantity of bronze, iron, and terra-cotta objects have been and are being found in the grounds, chiefly consisting of helmets, armillas, collars, buckles, nails, spurs, bows, rings, lances, spears, swords, and thousands of perforated bronze grains and beads, besides numerous objects of amber, glass, shells, and pottery, all of which are likely to be secured by the Italian Government for the Florentine Museums.

Two Prussian officers have arrived in Paris for the purpose of determining telegraphically the longitude of Berlin. Two French officers have been despatched to Berlin in order to carry out similar operations. The apparatus to be used in Paris have been located at Montsouris under the superintendence of M. Mouchez and the Bureau des Longitudes. The ultimate aim of the operation is to connect the French trigonometrical triangulation with the system of the Geodesical International Association which is covering almost the whole of Europe.

Book Review Supplement

Advising a President

Edward E. David, Jr

A Scientist at the White House: The Private Diary of President Eisenhower's Special Assistant for Science and Technology. By G. C. Kistiakowsky. Pp. xvii+448. (Harvard University: Cambridge, Massachusetts and London, 1977.) £11.25.

IT HAS BEEN said that history is not made, it is written. It is written after the fact from fragmentary and confused memories, from interpretation of hearsay by people usually not involved, or by using indirect evidence to buttress a preconceived theory. This book is not such a perversion. It has the ring of authenticity, written principally on the spot and at the time by a man involved directly in the affairs reported. From my own experience in the White House with similar situations, it communicates a true sense of the dynamics, the conflicts, the frustrations, the personal friendships and animosities, yet the euphoria and satisfactions of advising a President on matters where he is inexpert.

Dr Kistiakowsky has done a service by publishing his diary. As a diary, it focuses on events, not the process of science advising. As in a diary, specific subjects are fragmented temporally. For example, pieces of the story of the struggle for a nuclear test ban appear throughout the text. There has been no attempt to consolidate these except in brief comments at the beginning and end of the book. This is all to the good, in my opinion, for it lends reality to the account. Yet important issues themselves, such as machinations towards a civilian space programme, can be studied and documented. Scholars of events of that time will find the book indispensable.

For those interested in the process of science advising, the book will be a wellspring of information, even though the subject is hardly addressed directly. Indeed, to the perceptive reader, the process of advising (and the inevitable striving for influence) becomes starkly clear. The flow of events and the colliding opinions and egos document the most critical factor in science advising—knowing the President's deeply-held convictions and values (for example, as outlined above), and relying on them in advocating policy. Convictions and values of a President can sometimes be turned slightly by fact and persuasive argument, but not bent very far.

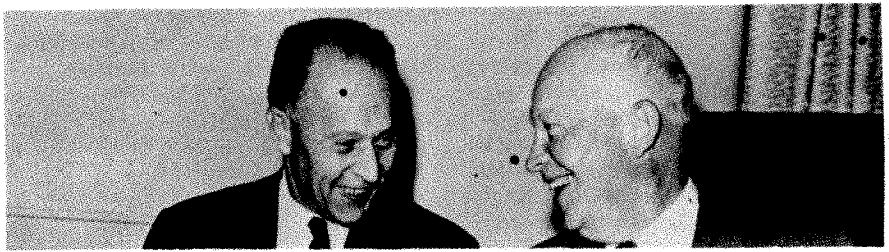
Also fascinating are the personal glimpses of President Eisenhower and his strong commitment to steps for peace. As a military man, he knew the fallibilities of the military, *and* their civilian bosses. He was well aware, too, that budgetary conservatism must be leavened with values which look to the long-term future. He was, therefore, favourable to science and respected the judgement of the professional people involved. The opinions and *modus operandi* of a variety of prominent people both in and out of government are described and judged by Dr Kistiakowsky. Many of them may have rejoinders, if they are still alive and interested. A bit more about that later.

The President's Science Advisory Committee (PSAC) emerge from the diary as a useful instrument, if somewhat obstreperous and self-possessed. The PSAC seemed to function best when it addressed topics at the forward edge of science of technology, but with modest immediate impact on budget, political, or social matters. The PSAC had its detractors on the political side in Dr Kistiakowsky's day as well as in mine. In later times, it became necessary to institute another mechanism—*ad hoc* panels reporting directly to the Science Adviser rather than through the PSAC.

The diary contains a number of significant truths, such as, "This alerted me again to the danger that a 'cold-blooded' scientist's opinion may be very poorly received by the public at large", referring to a PSAC panel's view on carcinogens in food. A larger, still vital truth emerges—that the government requires advice and counsel from knowledgeable private citizens at the top of their careers if it is to act wisely. It must create conditions in which both advisers and advisees are willing.

For me, the book brought back memories and stimulated reconsideration of my own experience in the White House. Perhaps most prominently, I am impressed that events have a startling continuity. Here, 17 years after the events described, many of the same issues are still before us. Only some of the players are different. For every topic that occupied Dr Kistiakowsky, I can recall a derivative topic that occupied me some 12 years later. He expended effort on the nuclear test ban, I on an extension of the ban and on SALT I. Principal players in his time were John McCone and Christian Herter; in my time, they were Henry Kissinger and David Packard. Dr Kistiakowsky was concerned about large space boosters, I about the space shuttle. He dealt with Keith Glennan and Herbert York, I with James Fletcher, George Low and Donald Rice (then OMB, now President, Rand Corporation). Dr Kistiakowsky worked on the carcinogenic content of cranberries and the rigid Delaney Amendment, I on the pesticide 2,4,5T and cyclamates (today, saccharin). His correspondent was Arthur Fleming, mine were Elliot Richardson and Charles Edwards. Dr Kistiakowsky tried to put forward an acceptable high energy physics programme particularly advocating the Stanford linear accelerator; I did likewise trying to keep accelerator facilities from budget-induced idleness, and I also advocated heavy-ion research and radio astronomy, including the X-ray spectrum. He dealt with Maurice Stans, I with George Shultz and Caspar Weinberger. Dr Kistiakowsky addressed the strength of Western *vis-à-vis* Soviet science, and that was a hot topic in my time too. Dr Kistiakowsky's time saw the demise of the U-2 and its surveillance of the Soviet Union. He also saw in the SAMOS programme—the beginnings of satellite surveillance as a replacement. This topic remained an important area for the science adviser until the end of my own term. The U-2 incident which 'spoiled' Eisenhower's tenure has led to a new era in which 'national technical means' is a technique accepted tacitly by both sides as insurance against military surprise. Thus, today's intelligence estimates can speak confidently about the size and character of Soviet miltary deployments and developments, even though the intent behind them is and will remain a subject of dispute.

But there were also new concerns in the early 1970s. Energy was a principal one; including the breeder reactor programme; so was health care, as distinct from biomedical research. (There was a concern in both areas about the performance and *modus operandi* of the NIH, a concern that persists at least in the political arena to this day.) Directed biomedical research, typified by the Cancer Crusade, became an unwise *cause célèbre* in the 1970s, beginning in the late 1960s under President Johnson. In my time, there was a social science focus on the adolescent maturation process. That concern was stimulated by the perceived decline in educational quality. There was increasing attention to social science research programmes and modelling as an aid to understanding their workings (including the Limits-to-Growth convulsion). And above all, there was the concern about environmental pollution and the drive to control it. A central issue in my time was the pollution caused by automotive and coal-burning plants.



Kistiakowsky (left) with Eisenhower

UPI Telephoto

Some of these 'new' subjects had begun to surface in Dr Kistiakowsky's time. But like an older person whose eccentricities have become exaggerated, the Science Adviser's office, as it matured in the 1970s, became more and more concerned with these 'offbeat' topics, which ranged far beyond the earlier principal concern—the physical sciences. The roots of this trend are clear in Dr Kistiakowsky's diary. Some say this was the downfall of the office, but it wasn't. It was a necessary evolution to keep pace with presidential interests.

Beyond both latent continuity and its contrast with future events, the diary indicates clearly Dr Kistiakowsky's incisive judgments about issues and people, some of the latter not very complimentary. Undoubtedly, those people would have retorts to Dr Kistiakowsky's judgment of them. Furthermore, events are described in the diary as perceived by Dr Kistiakowsky at the time. It is remininscent of the famous Japanese film, *Roshamon.* Its lesson was that each participant in a happening emerges with his own perceptions, very different from those of the others. Knowing that lesson, I took the liberty of talking with some of the other participants in a few of the events described in the diary. Indeed, at least two of those people had entirely opposite perceptions of the same events from Dr Kistiakowsky's, based not only on their memories but on their own diaries. Clearly, there has been no attempt to deceive the reader in Dr Kistiatkowsy's diary; rather, at work are the usual divergences of perceptions conditioned by participants' past experiences and personal egos, and the resulting preconceptions. Thus, the reader should realise that there are other sides to the stories as told in Dr Kistiatkowsky's diary. A tell-tale sign is that Dr Kistiakowsky saw his judgments in the complex matters he described as almost infallibly correct.

Significantly, Richard Nixon as Vice-President appears several times in the book. The text of the diary may leave the impression that he was often on the 'right side' of the argument, and so somewhat enlightened. Yet, there is a second impression which emerges on careful reading—that Nixon knew how to judge an occasion and take an acceptable position. Dr Kistiakowsky, in his notes added last year to his diary, says he came into the White House with a negative attitude towards Nixon, found him self-centred, and "remained sceptical to the end of my stay in Washington."

This book is the most significant account of the first era of Science Advisers yet published. The post was established in 1957 and abolished in 1973, about six months after I left the White House. It was re-established by an Act of Congress, signed by President Ford in May 1976. The Carter Administration's appointee is Dr Frank Press, an eminent and capable Earth scientist. With his installation begins a new era of presidential science advice. I hope that during its span, even greater accomplishments will be added to those of the first era—a significant piece of which is recorded in Dr Kistiakowsky's book.

An accolade is due to Professor Charles Maier who encouraged the publication and added a highly useful introduction to set the stage for the otherwise cryptic entries which follow.

Edward E. David, Jr, was Science Advisor to President Nixon and Director of the Office of Science and Technology (Executive Office of the President) from 1970 to 1973. He is now a consultant, based in Chicago.

New from Columbia

ESSENTIALS OF ASTRONOMY
Second Edition
LLOYD MOTZ and ANNETA DUVEEN
Now newly revised and updated, this standard text takes the reader from the classical astronomy of Copernicus, Tycho Brahe, Kepler, and Newton to the modern astronomy of quasars, neutron stars and black holes. It continues to serve a wide range of persons teaching, studying, and investigating contemporary astronomy. $18.75

THE BIOCHEMISTRY OF ADENOSYLMETHIONINE
FRANCESCO SALVATORE, ERNEST BOREK, VINCENZO ZAPPIA, HOWARD GUY WILLIAMS-ASHMAN, and FRITZ SCHLENK, Editors
S-adenosylmethionine is probably second only to ATP in the variety of reactions for which it serves as a cofactor. This book, containing articles by the world's leading researchers on adenosylmethionine, is a landmark review of the rapidly developing field.
Columbia Series in Molecular Biology $43.75

ORIGIN AND EARLY EVOLUTION OF ANGIOSPERMS
CHARLES B. BECK, Editor
In this gathering of new papers by prominent authorities, emphasis is placed on the time and place of origin, the biological source of the angiosperms, and selective pressures that might have influenced their origin and early evolution. The volume is extensively illustrated with maps, drawings, and photographs. $24.90

BIBLIOGRAPHY OF PLANT VIRUSES
HELEN PURDY BEALE, Compiler and Editor
The product of a lifetime of research and compilation, the *Bibliography* is the definitive reference volume for plant virologists, as well as for researchers in the biomedical sciences. Contains nearly 27,000 separate bibliographical references spanning eighty-seven years, and covers the literature of over one hundred countries and some twenty-eight languages. A lengthy subject index is included. $93.75

COLUMBIA UNIVERSITY PRESS

Circle No. 31 on Reader Enquiry Card.

Experimenta lucifera

Erwin Chargaff

The Professor, The Institute and DNA. By R. J. Dubos. Pp. 238. (Rockefeller University: New York, 1976.) $14.50.

In the late 1930s, during my early days at Columbia University, I had frequent occasion to visit the Rockefeller Institute for Medical Research, as it was then called. The uninviting structures on Avenue A near the East River were not easy of approach. True to its character of a citadel of learning, the door of the Institute was fortified by gruffness; and after passing inspection by Cerberus or Cerbera, the visitor had to be accompanied to his destination by a special young man. In my case this destination usually was the laboratory of the organic chemist Max Bergmann, much admired by me. I had known Bergmann when he directed a Kaiser Wilhelm Institute in Dresden; here in New York he shared the uneasy fate of his generation of German emigrants. On seeing me, he would exclaim: "*Zuerst rauchen wir eine Friedenspfeife!*" producing a large glass jar in which a package of cigarettes was kept in a controlled habitat. Occasionally, he conducted me afterwards to another laboratory, that of P. A. Levene or D. D. van Slyke; and sometimes I would come upon the light-brown shadow of an elderly mouse-like figure tripping along the corridor walls. This, I was told, was Dr Avery, a name not unknown to me as that of the greatest expert on the pneumococcus, although at that time I could not have known how important his name would become to me a few years later.

These reminiscences were brought on by an uncommon book about an unusual man, Oswald T. Avery (1877–1955). It is, in my opinion, a very good book, and I enjoyed reading it. As the title indicates, this is not merely a scientific biography. The book operates on several intercommunicating levels, taking into account the man, the time, and the place; and painting, with extraordinary competence, the ever-changing human and scientific backdrops. This competence is not entirely surprising: René Dubos, apart from being a very good writer, was a member of Avery's department from 1927 to 1941, and the warmth of personal contact and observation is felt throughout the narrative.

Born to English parents in Halifax, Nova Scotia, Avery was taken to New York City at the age of ten, when his father, who was a Baptist clergyman, was invited to be pastor of the Mariners' Temple on the lower Eastside, even at that time a pretty horrible part of the city. But five years later, the father was dead, and the three sons were brought up by the mother who must have been an energetic lady. Oswald Avery, aside from becoming an accomplished cornetist, got a good education: first something called, soberly, the New York Male Grammar School, then Colgate Academy, Colgate University, and finally, between 1900 and 1904, the College of Physicians and Surgeons of Columbia University, which was then one of the best finishing schools for clinicians. The latter seems to have finished him in more than one sense: in went a lively, communicative young man, majoring in the humanities, excelling in oratorical contests, playing the cornet, leading the Colgate University band, and clearly not particularly attracted to the natural sciences; out came what I would term, perhaps with some exaggeration, a scientific recluse. This shock of confrontation is not a very rare event: I have noticed it often in several generations of medical students, when I taught at the same medical school; only few of those affected, I am sure, turned into other Averys; mostly they became psychiatrists or even psychoanalysts.

Scientists in general lead uneventful lives, with the exception of the few who, for instance, are guillotined during the French Revolution or killed by highway robbers in Southern France. What counts is their inner history to which their published papers afford only precarious access, for the history of ideas, and especially of scientific ideas, is a slippery discipline. But in the present instance, Dubos has succeeded in producing as multidimensional an image as is possible.

With the exception of a very short period, after graduation, in medical practice, Avery devoted his entire life to research in bacteriology and immunology, first in a now extinct private institution, the Hoagland Laboratory in Brooklyn, and since 1913 in the Rockefeller Institute, where he remained until he was 71. The last few years of his life were spent, let us hope serenely, in the South. Or as Dubos puts it: "In 1948, he decided that he had shot his bolt; as he no longer felt able to function effectively in the scientific arena, he retired to Nashville, Tennessee". Each of the verbs in the preceding sentence could lend itself to a philosophical analysis which I shall not attempt here, except to wonder why society seems to reserve circus acrobatics and science for the very young, assuming that these occupations require muscular vigour rather than wisdom. Why had, for instance, Telemann not yet "'shot his bolt," when at the age of 81 he wrote what is widely considered as his greatest work, the oratorio *Der Tag des Gerichts*? The multiplicity of possible answers shows that we have not yet found the corect one.

The major part of the book is devoted to a detailed and lucid discussion of the problems investigated by Avery during his 35 years at the Rockefeller Institute. This is done in five chapters the titles of which will indicate the areas under study: 'The Lure of Antiblastic Immunity and the Chemistry of the Host'; 'The Chemical Basis of Biological Specificity'; 'The Complexities of Virulence'; 'Bacterial Variability'; and 'Heredity and DNA.' It will be recognised that Avery was one of the early microbiologists who understood the dominating role that chemistry was to play in biology. This was, incidentally, quite in harmony with the *genius loci* of the Rockefeller Institute, which in this respect, as in many others, was a most remarkable place. Dubos does full justice also to this side of his story; and the Institute, with its members, seminars, conferences, and, especially, its memorable capitalistico–monastic lunch room, is one of the indispensable elements of his account.

Avery was comparatively late in starting, but he lasted: his most important work was published when he was past sixty-six. The pneumococcus was his microcosm; he showed that general principles of great import can be derived from little things if it is given to the researcher to join penetration to perseverance, and bold deduction to honest induction. As always, what counts is the balance, the mixture; but has anybody in science succeeded in mixing himself, in filling his own recipe?

Avery became interested in the pneumococcus because one of the principal projects studied at the Rockefeller Hospital was the development of a serum therapy for lobar pneumonia. I do not believe the practical results of his research ought to be stressed, but out of this work there emerged a new understanding of the chemical basis of antigenicity, and, even more suprisingly, the recognition that genes were made of DNA. These glories may be taken to demonstrate the stupidity of our era of target-directed research. Actually, science has never operated entirely without goals; but the goals were chosen by a few reasonable men, not by frightened politicians or bureaucrats, and were enforced with

Standing: E. E. Terrell, K. Goodner, Dubos, F. H. Babers

tact and imagination. The directors of the Institute and the Hospital were wise enough to leave such a man as Avery in peace. They had trust in him; something that no 'peer group' with its silly priorities can afford or accomplish. The absence of frenzy is one of the main impressions I get from Dubos' description of Avery's laboratory.

The existence of many immunologically different pneumococcus types had been known for some time. In 1916, Avery's intimate friend, Alphonse Dochez—I knew him very well during his years as a Columbia professor—discovered that type-specific soluble material was released into the culture fluids by the organisms. These observations, extended and refined in the course of several years, finally led to Avery's collaboration with Michael Heidelberger, and later also with Walther Goebel, and to the identification of a host of type-specific bacterial polysaccharides as the basis of the immunological specificity of the various strains. It is not too much to say that this work had a profound influence on the growth of immunochemistry and on later concepts of "the chemical aspects of biological specificity." This was the title of the series of Jesup lectures that I gave at Columbia University four years after Avery's death. His name was mentioned more often than anybody else's, with the exception, of course, of my own.

Leaving aside a large number of interesting and important investigations by Avery and his collaborators—almost all within the confines of his 'pneumocosm'—I should like to move rapidly to what most of us will consider the most illuminating, the *luciferrimum*, of his many *experimenta lucifera*. (Dubos quotes Francis Bacon's distinction, in his *Instauratio Magna*, between "experiments of light" and "experiments of fruit.") I refer, of course, to the work on the biological activity of DNA. In view of the witches' brew now being stirred all over the world, with "recombinant DNA" as its main ingredient, I can only hope that the title of this essay will not have to be changed to *experimenta Luciferi;* although the Devil hardly needs experiments to make his point.

Less than sixteen years—1928 to 1944—were required for the first fundamental observation to lead to the definite proof that DNA was the instrument of genetic specificity. That it actually took much more time before this proof was accepted generally, was due to obtuseness, malevolence, and the desire to protect various vested interests. I remember the names of both the heroes and the villains in this story, but only a few of the first will be mentioned here. When the transformation of pneumococcal types *in vivo* was discovered in 1928 by F. Griffith, there were no loud objections, perhaps owing to the rapid confirmation of his findings in other laboratories or because most bacteriologists at that time were Lamarckians. But for some reason the observations were filed away and, had it not been for Avery, they might have slumbered a long time. It was in Avery's laboratory that Dawson and Sia achieved transformation in *vitro* and that Alloway described the isolation of a crude transforming factor. All this was accomplished before 1933; and Dubos takes great pains to explain why more than ten years elapsed before the next, and in every respect final, publication. Such explanations are really not necessary: before World War II, science was not yet an achievement sport; speed records formed no part of the accomplishments of a scientist as they do now. Griffith and Avery are both quoted as deprecating hurry; and Dubos tells us that Avery liked to recall "the words of an old black patient who watched, with amused surprise, the young doctors rushing about the wards of The Johns Hopkins Hospital: 'What's your hurry, Doc? By rushing that way, you passes by much more than you catches up with!'".

When in 1944 the epochal paper by Avery together with Colin M. MacLeod and Maclyn McCarty appeared, it certainly was something worth waiting for. The stages leading up to this publication and the all-in-all shabby reception granted it by the experts are well documented in the book, although more could, and probably will, be said eventually. As to the effect that the identification of the transforming principle as a form of DNA had on me and on the direction of my subsequent work, I have described it before. Avery himself obviously realised the implications of his discovery much more profoundly than he was willing to put into print. The letter he wrote to his brother Roy on 26 May, 1943, is particularly instructive in this respect. His entire character as a scientist—relentless perseverance, courageous imagination, extreme caution—can be developed from this document.

Many readers will, I am sure, find one chapter especially moving—namely, chapter twelve, entitled "As I Remember Him." I have never seen this done before in the biography of a scientist. To the limited extent that a scientific investigator is also a human being, the carving of the private bust calls for an unusually tactful and sensitive observer; and this René Dubos must have been in the many years he spent with or near Avery. Nevertheless, Avery was an extremely private person, and there must have been a wall around him, not of his own building—a wall that constrained him as it restrained access to him. I am not sure that we can ever understand another man so as to resurrect him on paper. The reason why figures invented by great novelists strike us as so alive is that they are invented. At any rate, what I got out of reading about this shy, puritanical, disciplined, and cautious man was a renewed awareness of the poverty of greatness.

As I said at the beginning, this is an interesting book. It is also very well produced, with 22 illustrations, some quite fascinating, and with a good index. It should be read by all who consider themselves part of the 'biomedical community', and molecular biologists should read it twice. Even philosophers and historians of science, if they can spare a few moments from their contemplation of the dark side of the Reverend Moon, will find the book profitable. ☐

Conversations with Haldane

Eric Ashby

The Man with Two Memories. By J. B. S. Haldane. Pp. 220. (Merlin: London, 1976.) £2.80.

THE style is unmistakable; it has the taut logic of Handel's music. So is the puckish barbed humour: "As I was at a day school, I did not adopt homosexual practices . . . ". And so are the sparks of exotic knowledge: "Of course I have a fair repertory of languages, including one or two unusual ones, such as Hittite, which I had to learn in order to study the earliest serious biological document, Kikkalish's instructions for training chariot horses." No-one but J. B. S. Haldane could write such stuff in such an enchanting style. Those who recollect his brilliant and sometimes exasperating conversation will find in this book a nostalgic re-creation of what it was like to spend an evening in his company. Those for whom J. B. S. Haldane is a somewhat romantic myth—a man who could turn from mathematical genetics to polemics on sociology in the *Daily Worker*, and who used to leave his laboratory at the end of term to spend the vacation in the civil war against Franco—will get an impression of what it was like to be a contemporary of the man.

I remember him at a dinner of the Society for Experimental Biology. It was a light-hearted informal occasion and for some reason J.B.S. was asked to make a speech. In that grave, hesitating voice, as though about to begin a scientific lecture, he said that although he could not bring himself to believe in heaven, he now had some inkling of what heaven would be like if there were such a place. For he had greatly enjoyed this dinner, "thanks to the delectable company of the young lady on my right and the young lady on my left. Now in a three dimensional world one can have only two ladies sitting next to one. Heaven I believe, might be conceived to be, a place in *n*-dimensional space, where one could therefore expect at dinner to enjoy the company of *n*—1 young ladies."

This book is a mixture of J. B. S. Haldane's startling breadth of knowledge with his sparkling and often grotesque imagination. It is a fantasia with a purpose. The purpose is to expose by ridicule the prudery and bigotry and credulity of twentieth century western civilisation and to put on record glimpses of the sort of utopia he himself would have enjoyed. It is a work published years after his death. The blurb on the dust cover suggests that it may be regarded as a philosophical and scientific testament. Anyone who opens it with this expectation will be disappointed. It has neither the cohesion or the conviction of a testament. It is a jumble of ideas, leaps of imagination, and exhibitions of prejudice which I don't think Haldane himself would have wished to publish. It has not got enough plot and movement to make it good science fiction, nor enough austerity of argument (and Haldane's scientific work was impeccably well argued) to make it good scholarship. Nor, I believe, did Haldane himself intend it to be in either of these categories. It is simply a feast comprising the after-dinner conversation of a man of extraordinary and fascinating personality.

The 'hero', James Robert Murchison, carries in his brain all the accumulated experience and response to experience of a British scientist. But there has also entered his brain and lodged there and become manifest to Murchison, all the accumulated experience of Ngok Thleg, a being from another planet. It is a case of memory transfer which can occur if two persons have similar genotypes. The planet from which Ngok's memory-and-experience bank comes has solved many of the scientific and social problems which perplex planet Earth. The people there may multiply by clones; anti-social behaviour is promptly cured by injections of drugs; the unit of time is that taken for light in a vacuum to traverse 2.317×10^{17} wavelengths of the red hydrogen emission line; cities are built of an alloy of titanium and are enclosed from the atmosphere, kept at a 10% higher pressure with pumps and filters to remove bacteria (disease, therefore, was an anachronism). There is some interplanetary travel; some computerised information services; and a little highly aseptic permissiveness: all developments which have made some headway since Haldane's death.

The book is unfinished. It is not the sort of work which readers of *Nature* need feel they *ought* to read. But if anyone who is going by train from, say, London to Edinburgh would like to have J. B. S. Haldane's company for the trip, talking rather as he did to me when I made that journey with him some 40 years ago, this book will give him that experience. ☐

Father of ethology

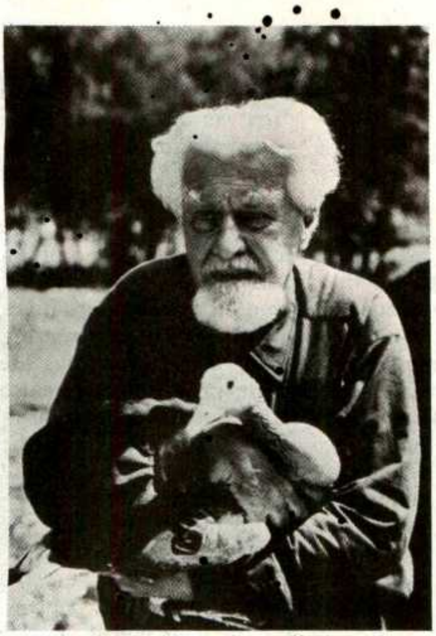
Aubrey Manning

Konrad Lorenz. By A. Nisbett. Pp. xiv+240+21 photographs. (Dent: London, 1977.) £5.95.

BIOGRAPHIES of living people, particularly those around whom controversy has gathered, are risky ventures. It is usually better to let the dust settle so that the subjects are seen more clearly in relation to their own time and place. Konrad Lorenz is clearly such a subject but Alec Nisbett's book is successful in avoiding the main pitfalls: this is a thoughtful and substantial biography. Nisbett has a background in mathematical physics but made a career in the British Broadcasting Corporation, where he has won many awards for his skills in presenting scientific subjects to the general public. His interest in Lorenz arose from such work, and having obtained grant to work on this biography, he spent much time talking to Lorenz and some of his key associates. Nisbett obviously likes Lorenz and so does this reviewer. Consequently for both of us there is the danger of becoming indulgent and less than adequately critical when discussing Lorenz's ideas and influence. This does set out to be a critical biography but the soft pedal is certainly applied in some places.

Konrad was the younger son of Adolf Lorenz, a successful orthopaedic surgeon (he almost got the Nobel prize for medicine himself) who identified with the Austro-Hungarian aristocrats and built himself a large house in the baroque style at Altenberg near Vienna. (Konrad has returned to this same house in retirement.) Adolf wanted his son to follow him into medicine: he did qualify, but already the jackdaws, herons, ducks and geese had taken over his life. Lorenz lectured on animal behaviour in Vienna, but had no formal research facilities; the animals all lived at home. During this period he published all his most influential papers and began collaborating with Tinbergen. Academic recognition was crowned by Lorenz going to the prestigious chair of psychology at Königsberg (then in East Prussia). The war had already begun and soon enveloped the eastern front. Lorenz ended up practising simple medicine and writing on philosophy in a Russian prisoner-of-war camp.

He was not repatriated until 1948 when he finally got back to Altenberg to reconstruct his career. It was much harder to regain academic recognition in Germany. No university position was forthcoming although a host of new students were gathering around Lorenz. He worked more or less on an *ad hoc* basis until the Max Planck Institute enabled him to obtain facilities at Seewiesen in 1955. He retired back to Altenberg with a smaller research institute in 1973.



Lorenz tending a wounded goose

Nisbett provides an excellent account of Lorenz's life and skilfully manages to interweave comments on his scientific thinking. I had some contact with the developments in the mid-1950s, and he very successfully catches the atmosphere of the post-War emergence of ethology in Europe. There can be no doubt of Lorenz's key role in its birth. He *is* the father of ethology, however many of his children now reject his ideas.

The early papers in which Lorenz developed the concepts of the fixed action pattern, the releaser and the evolution of displays, of action-specific energy and of imprinting, are all the result of dedicated observation and description shot through with brilliant intuitive thinking. The approach to the animal in its natural environment and the concern with function and evolution came as a powerful tonic to behavioural science stultified by white rat experimental psychology. To read Lorenz's papers was enough, but to hear him lecture—the flood of words and ideas enlivened by his repeated assumption of diverse animal forms on the platform—was to experience instant conversion. Ethology took off, and although Lorenz himself is quick to point out his debts to Whitman, Craig, Huxley and Heinroth, it was he himself who founded the school.

Lorenz's own great period was over by 1960. He had little taste for the quantitative and analytical studies which had to come next—he boasts that no paper of his ever included a graph; nor can I recall any tables. The new impetus was provided by Tinbergen, who rapidly built up a group in Britain, and by groups in the USA.

Lorenz turned increasingly to the application of his original ethological concepts to human behaviour and his weaknesses began to overlie his strengths. He had always tended to adopt rigid classifications in behaviour: instinct or learning, genes or environment. His disputes with the "English-speaking ethologists" as he referred to them, largely centred on their refusal to accept such dichotomies. Lorenz failed to appreciate that they were just as interested in the genetic basis of behaviour as he was, but often chose to approach the question through the study of development. It no longer remained helpful in such research to classify elements of behaviour according to any fixed scheme. When Lorenz began writing on the inherited basis of human behaviour he showed few signs of compromise. With the publication in English of *On Aggression* in 1966, the storm broke; Lorenz and those who supported his deterministic views on human behavioural development were ranged against the cultural and environmentalist schools.

As always in nature–nurture controversies, politics were to the fore. Lorenz's alleged Nazi sympathies during his Königsberg period were focussed on by the environmentalist left, especially when his Nobel Prize was announced. Nisbett provides a good account of the particular paper which gave such offence. He points out how certain mistranslations have been at the base of misunderstanding and misrepresentations. What Nisbett doesn't do adequately is to point out that whether or not Lorenz's views on the dire effects of domestication in man (whatever that means) were dressed up for Nazi consumption, they were in any case remarkably bad science.

Lorenz's reactions to the Nobel Prize furore saddened many of his friends. He admits himself that once on camera he becomes a buffoon. Instead of dismissing a youthful error at once, he tended to become defensive. He certainly gave a totally misleading impression at times. Nobody who knows Lorenz personally can doubt his warm humanity.

Nisbett's book will serve as an interim statement as it were. He gives a most useful list of references both to Lorenz's own work and to other writings which bear on his ideas. Perhaps the centre of gravity of this biography is inevitably towards the later period of Lorenz's career. Nisbett rightly feels that he must discuss Lorenz in relation to the controversies of recent years. When we come to look back at Lorenz's contribution in more tranquility, however, it is *King Solomon's Ring* that will stand out as his great book. Within its easy charm are all the important ideas which make up Lorenz's profound contribution to the study of behaviour. ☐

Richard of Wallingford

Richard Lorch

Richard of Wallingford: An Edition of His Writings, with Introduction, English Translation and Commentary. Edited by John D. North. Three Volumes: pp. 1,312; 22 plates; 128 text figures. (Oxford University: Oxford and London, 1976.) £75.

RICHARD OF WALLINGFORD (about 1292–1336) was among the ablest astronomers and instrument-designers of the Middle Ages. His *Quadripartitum*, for all its prolixity, bears comparison with Regiomontanus' *De Triangulis*, written a century and a half later; and his astronomical clock was one of the most advanced made in the fourteenth century. Again, the complex universal instrument 'Albion' ('All-by-one') was a remarkable achievement, and was fully appreciated by fifteenth-century astronomers such as John of Gmunden (about 1382–1442) and Regiomontanus (Johann Müller of Königsberg, 1436–76), who, among others, re-edited and commented on the *Tractatus Albionis*, in which Richard describes the instrument. Dr North has provided us with a reliable and annotated edition of all Richard's works. From this monumental edition, which must surely be ranked with Nallino's edition of Albategni, we may gain insight not only into Richard's achievements in astronomy, astrology, the making of instruments, and mathematics, but also into the progress of these sciences throughout the Middle Ages.

In studying any western astronomer of the high Middle Ages it is necessary to pay attention to borrowings from his predecessors, particularly the Muslim astronomers whose works were translated into Latin in the twelfth and thirteenth centuries. On the whole, Richard of Wallingford is explicit about his sources, but some problems remain. Thus, in the first part of the *Tractatus Albionis* he gives chapter and verse for each proposition, the usual sources being—besides Euclid and Ptolemy—Albategni's (died 929) *Opus Astronomicum* and an "abreviated Almagest". As is pointed out in the commentary, the latter is better known as the *Parvum Almagestum*. This is probably a Latin compilation and has been attributed (by A. Birkenmajer, *Studia Copernicana* I, 143–6) to one Walter of Lille, although Campanus of Novara (died 1296) is also a possibility. There are at least two variants of the *Parvum Almagestum*, quite apart from variations in the mainstream text, and one of these could well account for the remaining references to a "Commentator" on the *Almagest*. At all events, this Commentator is unlikely to be Averroës (1126–1198), whose commentary on the *Almagest* was apparently unknown in Latin (despite Birkenmajer's citation of the fourteenth-century Alphonse Dionysii de Lisbonne, who probably thought the *Parvum Almagestum* was by Averroës); and was so differently organised as to make the identification unlikely.

The sources of the *Quadripartitum* are not given with such readiness, but Dr North has discovered the most important of them: a text beginning "*Proporcio est duarum quantitatum* . . . ", which he for several reasons ascribes to Campanus. There are some valuable remarks in the commentary about the whole history of "cata" (Menelaus' theorem) and of ratios: it is to be hoped that these notes and the authors cited in them will encourage someone to make a critical edition of the main texts. The *De Sectore*, a reworking—apparently by Richard himself—of the *Quadripartitum*, is not printed in full. It is of some interest since it incorporates the new trigonometrical methods developed by the Muslim astronomers and introduced into the West by the translation of the astronomy of Geber (flourished during first half of twelfth century). Whether later English writers like Simon Bredon (about 1300–about 1372) copied Geber's methods direct or through the *De Sectore* is a matter for further research. What we do know is the approximate date of their introduction into England.

Richard of Wallingford (Cotton MS Nero D VII, f20)

Courtesy British Library Board

Of the shorter works the treatise on the "rectangulus" is perhaps the most interesting. Characterised by Henri Michel as "un véritable *Torquetum* schématisé", the rectangulus was invented by Richard to "obviate the tedious and difficult work of making an armillary sphere". (Anyone who has made even a rough model of an armillary sphere will sympathise.) Dr North points out that such alternatives cannot be lightly dismissed as observing instruments, and further maintains the unfashionable view that they were also used for the transformation of coordinates. It is interesting that in both the *Rectangulus* and the *Albion* Richard follows the custom, found among Muslim writers, of listing the parts of the instrument, together with their technical names. Franco's treatise on the "torquetum" is a possible intermediary.

Some of the texts included in this edition—for instance, the canons to John Maudith's tables, with which volume 1 begins—are here attributed to Richard Wallingford for the first time; and the authorship of doubtful cases, such as the astrological tract *Exafrenon*, is fully discussed. The account of Richard's life, besides being interesting in itself, contains some useful remarks on biographical sources for Englishmen of this period. The texts themselves are mostly established from two or three good manuscripts (in some cases discovered by Dr North), the others being used in a subsidiary role. There are occasional omissions—no doubt following Bjørnbo's edition of Thabit's *De figura sectore*—of purely repetitive matter, but synopses are given to fill the gap. On the whole, the English translation, on facing pages, is literal; but, where appropriate, the material is clarified by the use of modern symbols and line-by-line layout of the argument. As one would expect from the author of *Kalenderes Enlumyned Ben They*, the Middle English translation of the *Exafrenon* is given in preference to a modern one.

The three volumes are conveniently arranged so that the text and translation, commentary, and diagrams, can all be seen at once. In volume 3 there are plates, indexes, glossaries, and no fewer than 39 appendices. Some of these appendices and some of the longer disquisitions in the commentary volume are complete in themselves, and form a collection of well-indexed articles on the periphery of the central theme. We can only hope that their author is not preparing to abandon the Middle Ages. ☐

Worldwide Variation in Human Growth
PHYLLIS B. EVELETH and J. M. TANNER

The health of a population is most accurately reflected in the rate of growth of its children. It is this theme which underlies the analysis and presentation of what is by far the largest compilation of growth data ever assembled. The book explains in simple terms the different sorts of growth surveys, how to set about making them, and which sort to choose. All who are professionally concerned with child health should read it.

International Biological Programme Volume 8 **£20.00 net**

Microbial Energetics
Edited by B. A. HADDOCK and W. A. HAMILTON

The 27th Symposium of the Society for General Microbiology focuses attention of the cross fertilisation of ideas that are currently enriching the fields of bioenergetics and microbial physiology. This volume provides a timely and stimulating account of an important area of research that is basic to the biological sciences.

Society for General Microbiology Symposium 27 **£17.50 net**

Immunobiology of Gametes
Edited by M. EDIDIN and M. H. JOHNSON

A collection of articles which analyse the most recent data on gametes and fertilisation, concentrating mainly on functional aspects of the structure of gamete membranes and on the immunology and genetics of the egg and sperm. Critical discussion sections outline directions for new experiments and approaches and the book will be of importance to immunologists, developmental and membrane biologists as well as to clinicians in obstetrics, gynaecology and contraceptive research.

Clinical and Experimental Immunoreproduction 4 **£14.50 net**

Defence Mechanisms of Plants
BRIAN J. DEVERALL

A short and integrated account of the dynamic mechanisms involved in the defence of plant cells against attack by parasitic bacteria and fungi. The central interest of the volume is with the processes by which plant cells perceive the approach of an intruder and occasionally permit, but usually discourage, its further progress. The monograph will interest all who are professionally concerned with plant disease.

Cambridge Monographs in Experimental Biology 19 **£5.50 net**

Enzyme Kinetics
D. V. ROBERTS

The object of this book is to cover in a comprehensive manner the detailed kinetic analysis of a number of different enzyme models. All those topics in enzyme kinetics likely to be treated in an honours course in biochemistry are discussed, and the presentation is such as to enable the reader to develop more complicated enzyme systems. The book also includes sections on some more advanced topics, such as coupled enzyme systems and computer simulation of biochemical systems, which will interest postgraduate and research students.

Software Portability
An Advanced Course
Edited by P. J. BROWN

Software portability, the transfer of programs and data between different computers, is a subject of growing concern and importance. This course, on the latest state-of-the-art, is given by some of the foremost international experts. It should provide invaluable reading for all concerned with the transfer of programs and for anyone teaching or learning good programming practice. **£7.00 net**

An Introduction to the Study of Programming Languages
D. W. BARRON

There are hundreds of programming languages. How do they differ? How can they be compared? This text discusses programming languages in terms of general principles, illustrated by examples from the more popular languages. With emphasis on principles rather than techniques, Professor Barron introduces the basic concepts of programming language design in such a way that meaningful comparisons may be drawn between various languages. The book is intended primarily for undergraduate students of computer science.

Space and Time in the Modern Universe
P. C. W. DAVIES

An engaging and readable book in which Dr Davies explores the changing ideas of space and time particularly as illustrated by their application to astronomical and cosmological scenarios. Written in a straightforward style and enlivened by informal diagrams the book will appeal to undergraduate students, scientists requiring an easy review of modern developments and anyone with a scientific or philosophical bent.

Pulsars
F. G. SMITH

Professor Smith spent six exciting years on pulsar work at Jodrell Bank and this review of the discoveries and theory of pulsars draws from the flood of research papers that have appeared, as well as from his own work. His clear elucidatory style will make the book a pleasure to read not only by research astronomers but also by anyone with an interest in this subject.

Newton as alchemist

A. Rupert Hall

The Foundations of Newton's Alchemy. By B. J. T. Dobbs Pp. xv+300. (Cambridge University; Cambridge, 1976.) £10.50.

EVER since David Brewster published his Victorian biography of Isaac Newton 120 years ago it has been known that Newton devoted much time to chemical experiments and alchemical authors; indeed, Brewster, while faithfully noting his hero's purchases of chemicals, apparatus and Ashmole's *Theatrum Chemicum,* lamented his waste of time on Ripley, Flamel, Starkey and the rest. Moreover, Newton's interest in these matters has long been evident from his correspondence. The dispersal of the great mass of Newton's private papers in 1936 simply made openly available a mass of material that had been formerly known but largely inaccessible, and which in any case had not been regarded as very important to those who were more interested in Newton as the founder of mathematical physics than as a man of his own age.

The mood has changed, so that during the past thirty years many have pursued Newton the whole man, rather than the author of *Principia, Opticks* and some mathematical treatises. 'Freudian' analysis has laid bare the mechanics of his personality, and he has been portrayed as theologian, historian, Mint Master, magus, and most recently as alchemist. How much light all this knowledge derived from deep reading and wide scholarship actually throws on Newton's role in the history of mechanics or optics is still an undecided question. The first attempt, by David Castillejo, to discern a unity in all Newton's work has remained unprinted (although copies are on deposit in certain libraries). In her new study of the earlier phase of Newton's interest in chemical topics Mrs Dobbs, after setting out the background that Newton inherited, investigates the kind of information about the nature of metals that Newton was looking for in his alchemical authors, and relates this to his own experimental endeavours. Finally, like Mr Castillejo (but more precisely), she explores the relations between alchemy, theory of matter and the concept of gravitation.

There is a difficulty in this aspect of Newton's work—for it was certainly a serious enough activity to be judged work—which is encountered in studying Robert Boyle and others too. Newton actually published in his lifetime certain perfectly rational views about chemical properties and the nature of matter (which were not without influence on the development of chemistry as a science). We also possess factual and fairly straightforward accounts of experiments that he made on such and such days written in his own hand. We have again personal and authentic expressions of interest as in his letters to Aston (as early as 1669) and to Locke about Boyle's supposed incalescence of gold with mercury (August, 1692). And in his London years, later still, Newton kept up an acquaintance with the alchemist William Yarworth. Finally, there is the known extent of his own alchemical library and of his voluminous extracts from alchemical authors, by no means excluding those of the esoteric sort. What is largely (but not, it seems, absolutely) absent is any comment, explanation, or reworking of this last material from Newton's own pen. His purposes, his intentions, his possible ambitions in collecting and studying it, have to be for the most part inferred.

As is evident from Newton's published chemistry, and from the experimental records first analysed by my wife and myself many years ago, Newton's mind in all this worked at a rational, factual, indeed quantitative, level. In this respect Newton's pyrotechnical work shows no difference of principle from his work in optics. If this were not true it is impossible to understand how *Query 31* or *De natura acidorum* could have been written. Much as we proposed nearly twenty years ago, Mrs Dobbs writes of Newton's translating alchemical processes into chemical terms which he could then subject to trial in the laboratory. If he plunged for enlightenment into the "most esoteric and mysterious productions of the alchemists", he sought their meaning by 'rational analysis', and experimented methodically, almost ploddingly (pp168 and 175).

Illustration shows the 'greene lyon' devouring vivifying celestial influences, symbolised by the Sun, and emitting a vivified mercury, the living or 'actuated' character of which is symbolised by blood.

Stadtbibliothek Vadiana, St Gallen

In Boyle's and Newton's day it was of course perfectly rational to suppose that metals might be compound bodies and capable of chemical modification. According to Mrs Dobbs, in a manuscript of his own composition headed *Clavis* (Key), Newton wrote out a detailed account of a process for preparing "a mercury dissolving all metals, particularly gold". (Its humourless author noted that "one philosophical sign will appear to you: in the very making of the mercury there is a great stink".) Such solution was preliminary to the complete mastery of metals. Like Boyle, the writer of the *Clavis* saw gold apparently fermenting and changing colour in this menstruum.

What is rather at stake is the question of Newton's commitment to the alchemists' ideas. Did their writings not merely contain hidden clues to actual procedures which could be verified or falsified in the fire, but a profound esoteric insight into the workings of nature? Here (as also in Mrs Dobbs' conjectural "school" of alchemy in Cambridge, whose leading activists were Isaac Barrow and Henry More, with Newton as their neophyte) it is less easy to accord with her views. It is true that Newton in *Opticks* and in the discussion of comets in the *Principia* hints at the transformation of a cosmic 'spirit' into water and so (as Boyle thought he had proved) into earth; such a progressive coalescence of the fundamental particles of matter (neither fermions nor bosons!) was not forbidden by contemporary theory, and had indeed been invoked by Descartes.

There are other ways too in which, as Mrs Dobbs rightly points out, Newton's faith in the "analogy of nature" led him into strange, or at least empirically unjustified speculations. But it seems needless to derive the concept of gravitational "attraction" (which Newton after all declared did not need to be an attraction and was certainly not inherent in matter) from alchemical origins, and extreme to affirm that "in a sense the whole of his career after 1675 may be seen as one long attempt to integrate alchemy and the mechancial philosophy" (p230). Are the mathematical papers in Dr Whiteside's eight volumes equally to be seen as of no significance in Newton's intellectual development?

Nevertheless, even the reader who may feel some reluctance to substitute *Caput Mortuum* for *Caput Draconis,* and some suspicion of any single key to the secret of Newton's greatness (many have been offered), must find his understanding of Newton broadened and stabilised by Mrs Dobbs' explorations of the more obscure recesses of his mind. ☐

A. Rupert Hall is Professor of the History of Science and Technology at Imperial College, London, UK.

Scientific classic of history

J. D. North

Copernicus: On the Revolutions of the Heavenly Spheres. Translated by A. M. Duncan. Pp. 328. (David and Charles: Newton Abbot and London; Barnes and Noble/Harper and Row: New York, 1976.) £12.50.

JUST as in the Middle Ages the Bible and Liturgy were encased in Latin for the almost exclusive use of the priesthood, so in our own time most of the scientific classics of history remain either untranslated or—what is worse—badly translated. It should not be necessary to plead the case for a translation of the *De Revolutionibus* by Copernicus. The inadequacies of that prepared by Charles Glenn Wallis, and published in the series *Great Books of the Western World,* are easily exaggerated, but too numerous to make it an acceptable student edition. Dr Duncan's new translation is not only better, but it has the virtue of being separately available—that is, without an obligation to purchase the other 53 volumes of a collection.

Dr Duncan's style is modest, simple, and direct. His introduction could be readily understood by any sixth-former. The notes and introduction are not very long or profound, but neither are they likely to frighten away the inexpert reader. The heliocentric idea is kept to the centre of the commentary, where it belongs, psychologically if not technically. The simplicity of the commentary is, however, occasionally misleading —as when the so-called theory of trepidation is considered, and as when modern disputes over Copernicus' Aristotelianism and the reality of the spheres are deftly swept under the carpet. Copernicus's conservatism in the use of Ptolemaic methods and parameters is stressed, but Copernicus is represented as having made an advance on Ptolemy by the introduction of systematic observational tests of his model. The truth of the claim—simply because it is made so briefly in the introduction—is itself difficult to decide, but there are many who will find traces of special pleading in it, at least as far as it concerns Ptolemy.

The notes to the translation are slight and sparse, and the bibliography at the end even sparser. There are no indexes. The translation occupies almost nine-tenths of the book, and it is of course by this that the volume must primarily be judged. Speaking generally, the version is accurate and readable, and if it were possible to review the translation at pedantic length, most of my own objections would concern matters of taste rather than of substance. For example, out of kindness to the modern reader, *commutatio* is rendered as "parallax". On the other hand *obliquatio* is translated by the archaic "obliquation". I am not convinced that the flavour of the original is kept when *causa* is translated as "law" in such a context as Osiander's preface, as here: ". . . this subject [astronomy] is completely and simply ignorant of the laws which produce apparently irregular [planetary] motions". And I think that "correction" is an insufficiently specific rendering of *prosthasphaeresis.* But any careful reader of the text will not find much difficulty with technical terms.

The book is attractively produced at what must now be reckoned a very reasonable price, kept down by the expedient of printing the many figures in wide central margins. These are occasionally a trifle too small to be easily read, and are taken from the 1617 edition.

It must be noted that Dr Duncan's translation will soon be joined by another, produced by Edward Rosen for the Polish edition. The cost of the latter is likely to outstrip that of the David and Charles production, which is therefore more likely to reach the general reader, at whom the introduction and notes are aimed. Further comparison must be left until the Rosen translation is published. It is a moot point whether the market can take both versions, but English-speaking fans of Copernicus, working on the surgeon's principle that an extra opinion is always valuable, will no doubt insist that you cannot have too much of a good thing. ☐

State of the Universe

Stuart Sharrock

The Key to the Universe: A Report on the New Physics. By N. Calder. Pp. 196. (British Broadcasting Corporation: London, 1977.) £5.95. *From Quarks to Quasars: An Outline of Modern Physics.* By S. Thomas. Pp. viii+294. (Athlone: London, 1977.) £3.95.

VERY few books deserve to be read. Some are memorable for the information they contain and others for the pleasure they give. It is a rare delight to find a book that fulfils both these criteria. On the whole Nigel Calder's latest offering, *The Key to the Universe*, is such a treat. At times the complexity of the subject is overwhelming and tedium sets in, but these occasions are few and forgiveable. Most of the book manages to convey the sense of excitement and achievement so sadly missing in the majority of texts on physics. It must be admitted, however, that reading this book can be hard work—the very subject matter ensures this—but those who persist will be well rewarded. The great advantage compared with the television programme presented by Nigel Calder on the same topic, is that the concepts can be taken in at a leisurely pace and the reader can refer back to items which were incompletely understood at first sight.

The Key to the Universe is an attempt to explain in layman's terms the recent developments in elementary particle physics and astrophysics which promise to produce a theory of the workings of the universe. Beginning with electricity and rapidly plunging into the weak force and gauge theories, quarks, colour and charm, the story moves on to gravity and exploding black holes, the Big Bang and broken symmetries. These concepts are described in plain language and the text provides an excellent introduction to current beliefs concerning the origin of the Universe, how it works and how it is evolving. Only a Philistine could claim that this topic is not of interest; here it is presented in a manner which is accessible and enjoyable.

Like all good adventure stories there is a hero—the physicist. Not a single individual but a series of people doing experiments and propounding theories. The potentially obscure concepts are illuminated by this emphasis on the personalities behind the ideas. But the story presented is one of almost unqualified success, and consequently sounds at times a little contrived; it would be more realistic and gripping if the villains also made an appearance.

My major reservation is the fact that there are insufficient explicit statements about the relative standing of different concepts. Ideas are given more or less equal weight irrespective of their current status. The experimental basis for charm is rather stronger than that for the decay of the proton, for example, and the unification of electromagnetism and the weak force is considerably more advanced than unification schemes involving gravity. The unwary reader may not recognise this.

The initiated—whom are not synonymous with the intelligent—will no doubt find details which irritate. The muon, for instance, may well just be a heavy electron but it has had its own identity for decades; I find the label "heavy electron" bewildering and sad. But this is a minor level of complaint about an attempt to explain the workings of the Universe in 200 pages.

As a chronicle of recent achievements presented in an exciting and responsible fashion this book is unrivalled; the concerned reader will gain access and understanding to an important part of our culture, but not without hard work. This book demands to be read.

From Quarks to Quasars is an entirely different style of book. The suggestive title is misleading as only 10% of the text is concerned with astrophysical phenomena, and the message of the book is not the connection between theories of the microscopic and the macroscopic. No attempt is made to be up-to-the-minute—charm is still a dream of the future and black holes do not explode.

What is presented here is a competent introduction to the atomic nature of matter at an elementary and descriptive level; the basic concepts are introduced and applied to provide a useful summary of the various states of matter: gases, plasmas, liquids and solids. Properties of the nucleus and elementary particles are discussed almost as in a catalogue of 'useful facts', and the chapters on quarks and quasars are pure appendages.

This is a physics book containing a large amount of useful, well-ordered and basic facts presented at an elementary level in a readable but unexciting style. It is ideal background reading for budding physicists about to start a university course; the uncommitted will find it useful but uninspiring. ☐

Stuart Sharrock is Physical Sciences Editor of Nature.

Remarkable progress in astronomy

Bernard Lovell

Astronomy Transformed: The Emergence of Radio Astronomy in Britain. By D. O. Edge and M. J. Mulkay. Pp. xvi+482. (Wiley–Interscience: New York and London, 1976.) $31.75; £19.25.

HALF way through this book the authors state that they have completed their historical survey of the growth of radio astronomy. Their survey is primarily centred around the emergence of the new science in the UK covering the period from 1945 to about 1960—extended to 1963 to cover the discovery of quasars and, briefly, of pulsars in 1968. The authors state that they have chosen to base their description "around the development of research into discrete radio sources", and within this restricted timescale and framework they have pursued their aim with great determination. Supported by extracts from taped interviews with many of the participants, and by a most thorough series of references to the literature, a detailed account has been given of fifteen years of remarkable progress in astronomy.

In 1946, J. S. Hey published the evidence that a localised source of radio emission existed in the constellation of Cygnus. He and his colleagues had used the receiver section of an Army defence radar, and no-one could have foreseen the extent of the technical developments which were to follow during the next two decades leading to the discovery of thousands of discrete sources of radio emission. Edge and Mulkay provide a fair and largely unbiassed account of the succession of arguments and confrontations which by the end of their review period had led to a general consensus of opinion that the majority of these sources were extragalactic and that the measurements of their angular diameter and intensity distribution were of cosmological significance—even if the nature of the significance remained in dispute. After the pioneer work of Hey this story centres largely around the developments at Cambridge, Jodrell Bank and Sydney, and some of the participants will no doubt be surprised to be reminded how rapidly their opinions changed.

The meeting of the Royal Astronomical Society in October, 1951, was the occasion of a memorable exchange between Gold, Ryle and Hanbury Brown; and it is a pity that the full extract from this (like much other important material) has been relegated to appendices of notes and references which greatly increase the difficulty of a thorough study of the book. By 1951, although a few of the radio sources had been identified with extragalactic nebulae, Gold was almost alone in maintaining that the majority of the radio sources must be extragalactic. Even by 1957, when several thousand radio sources had been delineated, only eight had been identified optically; and three of these were associated with nebulosities in the Milky Way. By that stage the astronomical community was immersed in the contentious arguments about the differences between the Cambridge and Sydney radio source counts and whether they had relevance to the cosmological problem. Since Dr Edge was a graduate student in the Cambridge group for four of these remarkable years, he has been able to penetrate the details of a complex story, confused by the fact that, on the wavelengths then in use, the three strongest radio sources were near the galactic plane; but whereas two were supernova remnants in the Milky Way, the second strongest was a remote and peculiar extragalactic object.

The scope of the second half of the book is different. Here the authors investigate the relationships between the various groups of radio astronomers, the differing developments of the individual groups, the effect of radio astronomy on classical optical astronomy, and the extent to which the study of the emergence of radio astronomy contributes to the more general problems of the development of new areas of scientific inquiry. Parts of this will form compulsive reading for those who were in any way associated with these developments.

The bitter dispute over the radio source counts between the Cambridge and Sydney groups is summarised fairly. The remarkable secrecy maintained by Hewish and his colleagues over the pulsar discovery is described in relation to the problem of cooperation and competition, but the authors have balked the task of penetrating the Cambridge observational/theoretical conflict which has had such an influence on the present organisation of theoretical astronomy in the UK. In fact, their comment on this important matter is relegated to a footnote near the end of the book in which, referring to Hoyle, Gold and Bondi, they remark that the three "found themselves in Cambridge, but without any meaningful relationship to the small observational radio astronomy group, with whom they found dialogue difficult".

The most unsatisfactory feature of the book is the long chapter on *The Social Structures of the Groups* in which the authors "attempt to build up a picture of the evolution of the social structure and differentiation within the Cambridge and Jodrell Bank groups". They do this in a most peculiar manner—from "publication profiles, and co-authorship and citation statistics", and by quotation from anonymous members and ex-members of the two groups. The recollection of struggling research students of twenty to thirty years ago—however eminent they may be today—is scarcely a satisfactory means of making this investigation. In fact, I have difficulty in regarding this chapter seriously as a work of scientific or social investigation especially when after 57 pages the conclusion is reached that "the differences between the two groups can be adequately explained by postulating simply that Ryle and Lovell 'are two different people'. It is our view, however, that such a move is unnecessary". We *are* different people and it is those differences embraced within a framework of mutual understanding and collaboration about the problems of development in a society with limited resources which have enabled both of our groups to survive and develop.

This chapter suffers in comparison with the following chapter on *Some Sociological Implications*. This is by far the most important and valuable section of the book in which the innovation of radio astronomy is placed in the historical context and compared with the emergence of other new scientific disciplines. Particular comparisons are made with Ben-David's study of nineteenth-century innovations in medical science, of Mulkins' study of the orgin of molecular biology, and of the study by Dolby of the emergence of physical chemistry in the nineteenth century. This is a significant contribution to the scarce literature on a subject which should be of great concern to contemporary society, and is worthy of wider circulation than it is likely to obtain in this book. Clearly, Edge and Mulkay have condensed their information from an analysis of a great deal of published work and taped interviews; but further substantial sections could have been excised before publication, without detracting from a valuable historical narrative. ☐

Sir Bernard Lovell is Professor of Radio Astronomy and Director of the Experimental Station at the University of Manchester Nuffield Radio Astronomy Laboratories, Jodrell Bank, UK.

WILEY INTERSCIENCE

THE PHYLOGENY OF VERTEBRATA

by **S. Løvtrup**, *Department of Zoophysiology, University of Umea, Sweden.*

Professor Løvtrup's particular approach is to submit a theory of phylogenetic classification in which he attempts to establish the ancestry and divergence of the vertebrates. His conclusions are in some cases unexpected and rather heretical.

A theory of evolution is also proposed in which it is claimed that many evolutionary innovations have involved large-scale changes.

0471 99412 X 342 pages April 1977 £15.00/$29.50

COMPUTED BRAIN AND ORBITAL TOMOGRAPHY: Technique and Interpretation

by **C. F. Gonzales**, *Hahnemann Medical College and Hospital of Philadelphia;* **C. B. Grossman**, *Milton S. Hershey Medical Center;* **E. Palacios**, *Loyola University Medical Center;* and **J. L. Parr**, *Hahnemann Medical College and Hospital of Philadelphia.*

A simplified, succinct, and graphic approach to the fundamental principles, technique and interpretation of computed brain and orbital tomography. Topics include: Basic Physical Principles: Artifacts and Sources of Error; CT Scanning: Diagnostic Approach; Neuroanatomy: Correlative Anatomy and CT Scanning; Pathological Conditions: Neoplastic Disease; Vascular Disease; Neurocutaneous Disorders; The Orbit: Orbital Anatomy and Pathology, and New Developments in CT Scanning.

0471 01692 6 288 pages March 1977 £21.75/$36.85

PRINCIPLES OF ULTRAVIOLET PHOTOELECTRON SPECTROSCOPY

by **J. W. Rabalais**, *University of Houston.*

Discusses the phenomenon of photoionization and its resulting consequences by means of modern quantum chemical methods. Presents some of the highest resolution photoelectron spectra available to date many of which have not been published previously.

Wiley Interscience Monographs in Chemical Physics.

0471 70285 4 472 pages April 1977 £22.50/$36.00

BIOLOGICAL EFFECTS OF MICROWAVES

by **S. Baranski**, *Institute of Aviation Medicine,* and **P. Czerski**, *National Research Institute of Mother and Child.*

This book presents a critical survey of the literature on the biological effects of microwaves. Included are microwave generation and propagation, mechanisms of interactions of microwaves with living systems, experimental data on the biological effects of microwaves, a review of the health status of personnel professionally exposed to microwaves, and a review of safe exposure limits adopted in various countries.

0470 99041 4 234 pages April 1977 £9.00/$15.25

Published by Dowden, Hutchinson & Ross Inc., and distributed by John Wiley & Sons Ltd.

ENERGY, ENVIRONMENT, POPULATIONS, AND FOOD: Our Four Interdependent Crises

by **G. L. Tuve**, *Case Western Reserve University.*

A concise easy-to-read text, giving factual information and discussion on the four interrelated problems of energy, environment, populations, and food. Discusses planning for American economic, social and personal futures.

0471 02091 5 278 pages March 1977 £11.00/$19.00(cloth)
0471 02090 7 " " £5.95/$10.30(paper)

STRATEGY OF POLLUTION CONTROL

by **P. M. Berthouex** and **D. F. Rudd**, both of *University of Wisconsin, Madison.*

This deals with water, air, and land pollution as an integrated whole using innovation and logical design for solving pollution control problems. Stresses the importance of accounting for material and energy, exploitation of chemistry and biological reactions, synthesis of integrated sequences of reactor material, separation systems, and policy evaluation.

0471 74449 2 590 pages March 1977 £14.20/$24.00

X-RAY FLUORESCENCE ANALYSIS METHODS FOR AEROSOL AND WATER POLLUTION SAMPLES

edited by ***T. G. Dzubay****, Research Physicist, Environmental Science Research Laboratory, U.S. EPA Research Triangle Park.*

At a time of heightened awareness of potential health hazards to communities exposed to various substances in the drinking water and in the atmosphere, this book presents approaches and methods for analyzing trace elements in atmospheric aerosols and in water using X-ray fluorescence spectrometry. This book brings together the contributions of the chemists and physicists who have made advances in the field of X-ray spectrometry for trace element analysis in the environment.

0250 40134 7 320 pages April 1977 £18.50/$30.25

Published by Ann Arbor Science Inc., and distributed by John Wiley & Sons Ltd.

SMOKE, DUST AND HAZE: Fundamentals of Aerosol Behavior

by **S. K. Friedlander**, *California Institute of Technology.*

This text concerns the fundamentals of aerosol behavior. The first half of the book focuses on particle transport and optical properties of aerosols. The second half discusses the dynamics of size distribution. Worked examples and problems are included after each chapter.

0471 01468 0 338 pages April 1977 £11.35/$19.50

An Introduction to Biophysics

By CHRISTIAAN SYBESMA

This volume forms the basis for a complete introductory course in biophysics. The first section places biology within the context of the physical sciences and defines the cell and its constituents. Treatments of the relationships between molecular structure and biological function follow essential life processes (comprised under the heading bioenergetics) and the sensory systems are discussed next, and a final chapter is devoted to theoretical biology, an area of biology which emerged very much by virtue of the physical sciences-approach to biology. Although the author assumes a familiarity with the elements of calculus quantum mechanics, and thermodynamics on the part of the chemist or physicist, he does include appendices on elementary quantum mechanics and thermodynamics which render the book suitable for a more general audience.

1977, 286 pp., $19.50/£13.85 ISBN: 0-12-679750-1

Second Edition

Gene Activity in Early Development

By ERIC H. DAVIDSON

First published in 1968 and now completely revised and updated, *Gene Activity in Early Development* provides a novel and critical treatment of selected key topics in the molecular biology of animal development. The emphasis is on the role of the genetic apparatus in the processes of oogenesis and early embryogenesis. Thus the molecular biology of nucleic acids and proteins in developing systems is a central issue in this book. The author includes a general summary of renaturation and hybridization kinetics and a quantitative review of data on nucleic acid synthesis and turnover, and protein synthesis during early embryogenesis.

1977, 464 pp., $18.50/£13.15 ISBN: 0-12-205160-2

Reproduction of Eukaryotic Cells

By DAVID M. PRESCOTT

The primary purpose of this volume is to integrate recent discoveries about the molecular biology of the cell cycle into a comprehensive explanation of cell reproduction—its regulation and disruption of its regulation. The author has organized into a single discussion the principal facts and observations on the cell life cycle, and on the reproduction of eukaryotic cells. His integrated, up-to-date treatment adds considerably to our overall understanding of how cells reproduce themselves and how this reproduction is regulated—matters currently of key significance in the biological and biomedical sciences.

1976, 192 pp., $14.50/£10.30 ISBN: 0-12-564150-8

Pathology of the Lung 3rd Edition

Editor: **H. SPENCER**, *St. Thomas's Hospital Medical School, London*

An up-to-date new edition of a major reference work in the field of Pulmonary Pathology. Every chapter has been thoroughly revised and many new sections have been added. New additions to the varieties of lung tumours have also been included and extensive changes made to the chapters on the pulmonary reticuloses and hamartomatous states.

As in previous editions the emphasis has been directed primarily towards the pathology and pathogenesis of the disease, and this has been integrated with the clinical aspects in most cases.

Industrial Energy Conservation

A Handbook for Engineers and Managers

D.A. REAY, *International Research & Development Co. Ltd., Newcastle-upon-Tyne, England*

Provides plant engineers, energy managers and others in industry with a broad insight into the economics and practical engineering aspects of energy usage and cost. It contains the answers to questions which confront every responsible plant engineer who is concerned with the efficient utilization of energy. It presents a practical guide to a variety of energy-conserving measures relevant to a wide range of industries, with an emphasis on practical application.

Chemical Engineering

Volume 1 3rd Edition

J.M. COULSON, *University of Newcastle upon Tyne* and **J.F. RICHARDSON**, *University College of Swansea*, with the editorial assistance of **J.R. BACKHURST**, *University of Newcastle upon Tyne* and **J.H. HARKER**, *University of Newcastle upon Tyne*

This well established and highly regarded textbook which covers the physical basis of the three major transfer operations of fluid flow, heat transfer and mass transfer has now been considerably extended and modernised. In addition, the SI system of units has been incorporated and a new section on the flow of two-phase gas-liquid mixtures has been added to reflect the increased interest in the gas and petroleum industries.

Independent opinion of Volumes 1 and 2

"These two volumes are outstanding in this field and present a formidable challenge to all previous chemical engineering textbooks."

Optical astronomy

Bernard Pagel

Sterne—Kosmos—Weltmodelle. (Erlebte Astronomie.) By O. Heckmann. Pp. 353. (Piper: München and Zürich, 1976.) DM36.

THIS book is a collection of essays by the most distinguished living German optical astronomer and theoretical cosmologist of what is now the older generation. Scientific and autobiographical material is combined to make an unusually lively and lucid account in non-technical (German) language of the developments in which he has played a leading role: cosmology, positional astronomy, star clusters, development of the Hamburg Observatory (of which he became Director in 1941 after a four-year interregnum due to reservations as to his acceptability by the Nazi authorities), and the foundation of the European Southern Observatory (ESO, of which he was the first Director General from 1962 until his retirement in 1969). There are also shorter articles, including an obituary of the great Walter Baade, a Presidential address on the 50th anniversary of the International Astronomical Union and some experiences that read like short stories.

In the section on cosmology (described with deceptive modesty as the author's 'hobby'), the most interesting chapter provides an account of the history of the subject, his own involvement therein, and its relationship to German politics in the Nazi era. In the face of the official and noisy campaign against "Jewish physics", Heckmann held seminars on special relativity and on cosmology in which he took pains to expose the futility of such distinctions; and in 1942 (by which time that campaign had lost some steam) he published an important monograph on *Theories of Cosmology* which gave clear expositions of Newtonian, general relativistic and kinematic cosmology, but nevertheless got past the censor (perhaps because its arrangement so clearly brought out the connections between them), earning international acclaim. After the war, Heckmann continued to make important contributions to the foundations of cosmology until deflected by the departure of his collaborator, E. Schücking, and his own involvement with ESO. He gives a very clear and thoughtful description, enlivened with personal experiences, of developments up to the present, together with further chapters on historical and philosophical aspects.

Heckmann's chief personal contributions to optical astronomy were in the study of open star clusters (largely in collaboration with H. Haffner), notably the precision colour-magnitude diagram of Praesepe. The astrophysical significance and the enormous work involved in reaching a degree of accuracy unprecedented in 1937, are very well described, although in this case the absence of any diagrams from the book is a weakness. At Hamburg, clusters continued to be a major preoccupation; another was positional astronomy—completion of the AGK2 and launching of the AGK3, which now provides proper motions and spectral types for 180,000 stars. Situated 20 km east of the city centre, Hamburg Observatory emerged from the War almost unscathed, although there was a narrow escape in the final battles around Lüneburg. After the War its staff was enlarged and its facilities enhanced with an 80-cm Schmidt telescope originally planned in 1937 in the hope of attracting Baade; it took immense political skill to get renewed funding in 1948. Significant studies of galactic structure were carried out with this instrument in the late 1950s, but its usefulness was already becoming restricted by city lights; and it has now been moved to the new Spanish–German observatory near Almeria.

The ESO project was suggested in 1953 by Baade as a means of redressing the balance both between the Northern and Southern Hemisphere and between US and European optical astronomy; to save time and money, direct copies of Californian telescopes were to be used. Governmental support was rapidly secured in Holland, Belgium, Sweden and West Germany, and later in France and Denmark; and the Ford Foundation contributed a million dollars. Progress was slow, however, until the 1960s when the site of La Silla in the Andes was finally adopted after extensive site-testing in South Africa and Chile. It now boasts a fine collection of instruments including a 3.6-m Ritchey–Chrétien, together with offices and laboratories in La Serena, Santiago and Geneva—a far cry from the quick project based on existing designs envisaged by Baade, but nevertheless a great achievement which owes much to the energy and foresight of its first Director-General.

Heckmann's book gives a rounded picture of a man who has served the scientific community well through his thoughtful intelligence, integrity and very considerable courage, together with outstanding scientific and international vision, applied with great administrative and diplomatic ability. It is well worth reading, also, as an authoritative and often engagingly frank account of some of the most important developments in cosmology and optical astronomy in recent years. ☐

Bernard Pagel is Deputy Chief Scientific Officer at the Royal Greenwich Observatory, and Visiting Professor at the Astronomy Centre, University of Sussex, UK.

JOURNAL OF NEUROBIOLOGY
An International Journal
Editor-in-Chief: **Graham Hoyle,**
University of Oregon

JOURNAL OF NEUROBIOLOGY was launched in response to the rapid expansion in neuroscience research that occurred in the 1960's. It serves the needs of investigators working in new areas as an established outlet for both vertebrate and invertebrate studies.

The new Editor-in-Chief, Graham Hoyle, intends to establish a trend in a particular, though broadly-based, interdisciplinary direction. The common theme will be: *how nerve cells generate behavior.* Work on all types of organism, at all levels, and utilizing any kind of technique will continue to be published, but preference will be given to papers that contribute to this central theme.

DEVELOPMENTAL PSYCHOBIOLOGY
An International Journal
Editor-in-Chief: **Gilbert W. Meier,**
University of Nebraska Medical Center

DEVELOPMENTAL PSYCHOBIOLOGY is a forum for important research concerning the effects of physiological, environmental and genetic conditioning on an organism's development and later functioning. Primary emphasis is on studies examining the neurological, endocrinological, enzymatic and behavioral systems of humans and animals treated experimentally during the early stages of life. The journal also publishes purely descriptive and theoretical papers.

Nineteenth century kinetic theory

N. Feather

The Kind of Motion We Call Heat: A History of the Kinetic Theory of Gases in the 19th Century. Book 1: Physics and the Atomists. Pp. xxxix+1–302. Book 2: Statistical Physics and Irreversible Processes. Pp. xxxix+303–769. By S. G. Brush. (North-Holland: New York and Oxford, 1976.) Dfl. 210; $83.95 the set.

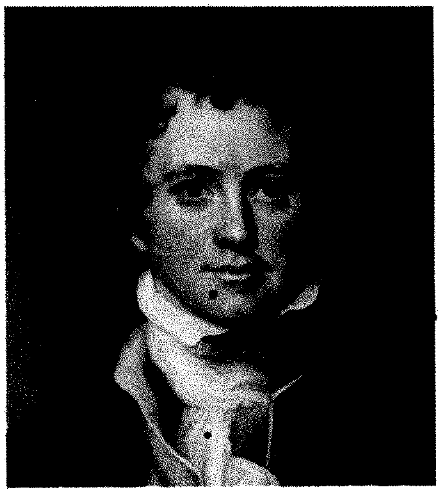
IT is not until he reaches p168 of this weighty monograph that the author admits that its title is taken, in literal translation, from that of Clausius' paper of 1857 which, as he says, "defined the scope and viewpoint of most 19th-century work in the kinetic theory of gases". Nothing else in the monograph is similarly derivative. Since he was invited to deliver a seminar at Harvard in 1954, Dr Brush has immersed himself in his chosen subject, and has written copiously about it. The present publication is a re-presentation and up-dating of the contents of 17 articles (the author says 15) which appeared under his name (one with C. W. F. Everitt as collaborator) in various journals between 1957 and 1974. These have been organised in two sequences. In Book 1 are accounts of the relevant contributions of seven individuals, from John Herapath (1790–1868) to Ernst Mach (1838–1916); in Book 2 discussions of seven 'problems' which exercised the minds of nineteenth century scientists and philosophers—problems ranging from "the wave theory of heat" to "Brownian movement". These two sequences are prefaced by a 100-page "introductory survey", specially written to give coherence to the whole work.

This is an interesting arrangement; however, as the author concedes, it "obviously entails considerable redundancy". "That may not be a disadvantage", he adds, optimistically, " . . . the reader can jump into the . . . chapters in almost any order . . . without losing too much of the overall picture". Unhappily, such licence is not vouchsafed a reviewer—although when he meets an outline of the derivation of Boltzmann's H theorem for the third time he is tempted to skip.

The chapters are divided into sections, and footnotes are collected together at the end of each section. There are some 108 sections so annotated, and with the number of sectional footnotes ranging from 1 to 59, it will be clear that the publishers' claim that "the author's historical researches have gone far beyond any other books on the subject" has at least statistical justification. Moreover, the last 49 pages of the monograph contain a separate bibliography, with brief indication of content, of 539 publications, listed by authors arranged alphabetically. These publications, Dr Bush considers, constitute the essence of the matter, so far as the nineteenth century is concerned. He has cited "thousands" of others in the footnotes—but he admits that they are "minor works".

What, then, has this monumental effort achieved? A balanced account of the history of the development of the subject within the century surveyed—that cannot be gainsaid—and a redistribution of emphasis and credit. Credit to Herapath and Waterston for being in advance of their time (largely because the notion of heat as a wave process, which became popular in the early years of the ninteenth century, went far to diminishing the impact of the experimental researches of Rumford and Davy). Similar credit to Leslie as the first to distinguish the three modes of heat transfer. Credit to Loschmidt and E. P. Culverwell for pertinent criticisms which led Boltzmann to a deeper study of his statistical theory. And, in respect of the last years of the century, a reappraisal of the discontents which beset kinetic theorists generally—the problem of gaseous specific heats seen as a minor problem, in comparison with more fundamental doubts of a quasi-philosophical character concerning randomness and irreversibility.

No-one will read Dr Brush's account without having his horizons widened and his detailed knowledge of the history of the subject immeasurably increased. It must be said, however, that he is likely to be much irritated in the process. Leaving aside the 'redundancies' in text and footnotes (it would seem almost as if the field is wide enough to sustain an ergodic theorem in respect of the continuing theme of this book), he will be irritated by the numerous textual errors and misprints.



Experimentalist Humphrey Davy

Photo: Mary Evans Picture Library

As a matter of interest, I checked the examples noticed during a single reading of chapters 11 and 12 against the relevant articles in *American Journal of Physics* where the material was originally published. I found three cases in which a typographical or textual error was repeated from the original version, and fourteen examples of errors newly appearing—five in new matter, and nine in places where there had been no error before. One example of the latter class is particularly puzzling. On p413, the factor $(1+(b/v))$ in equation (13)—which was correct—has been replaced by $(1-(b/v))^{-1}$, although the whole point of the argument in the following paragraph turns on the retention of the correct form in the equation.

There is an interestingly gratuitous error in the introductory survey (p43). Traversing a field of physics less familiar to him than gas theory, the author is presenting the old story of Fresnel and Poisson and diffraction by a circular disc. Poisson, he says, concluded that, if Fresnel were correct, "there should be . . . a tiny bright spot at a certain distance behind the disk". When the test was made, "the bright spot appeared just where the mathematics predicted".

In a work of the magnitude before us, occasional errors are inevitable, but, sadly, there are more than they should be; and some will almost certainly mislead. American usage, too, is sometimes subtlely different from our own. One example will suffice. Cayley is described as a 'colleague' of Tait (p358). Cayley, however, had left Cambridge before Tait went up as an undergraduate; by the time he returned, Tait was already in Edinburgh. They were never workers in the same institution. This usage, however, seems not to be accidental. In his preface, Dr Brush has a list of 22 "colleagues", the world over, whom he thanks for "valuable suggestions and information". At least he does not call his helpers "co-efficients", as Kelvin did (preface, *Baltimore Lectures*). Incidentally, Kelvin's nephew, J. T. Bottomley, worked, not "in England" (p520), but in his uncle's laboratory in Glasgow—and Oliver Lodge published (in 1894), neither from London nor from Birmingham (p745), but as professor in Liverpool. ☐

N. Feather is Emeritus Professor of Natural Philosophy at the University of Edinburgh, UK.

The Development of X-ray Analysis

SIR LAWRENCE BRAGG

"It is a textbook designed to share with the reader the author's own pleasure in the elegance, excitement and widespread relevance of his subject. . . . To sum up, this book can be read with pleasure and profit by people of very different backgrounds; it should certainly be read by anyone teaching crystallography at any level." *New Scientist. £6.50 net*

An Atlas of Optical Transforms

C. A. TAYLOR/G. HARBURN/
T. R. WELBERRY

"The exposition here (and, indeed, throughout the book) is admirably clear, and all the points made are lavishly illustrated by many beautiful reproduced diffraction patterns. All crystallographers, and diffractionists, are strongly advised to read this book; they will get much pleasure and profit from it." *Nature. Hardback £6.00 net, Paperback £3.25 net*

The Perception of Light and Colour

C. A. PADGHAM/J. E. SAUNDERS

LOCAL CIRCUIT NEURONS

Pasko Rakic

"Local Circuit Neurons" is used here to define cells that connect to other cells within the vicinity of the same structure rather than to cells in distant brain structures or organs. The author covers the historical background and distribution of LCNs and changing concepts in the light of recent discoveries. It describes the physiological properties of LCNs and theoretical considerations on the functional relationship between mitral and granule cells in the olfactory bulb. Methods for the analysis of local neuronal circuits are presented, and LCNs and neuronal circuits in different structures of the central nervous system are described. The book also takes into account phylogenetic and ontogenetic factors.

BIOCHEMICAL SYSTEMS ANALYSIS

A Study of Function and Design in Molecular Biology

Michael A. Savageau, *University of Michigan*
Foreword by Robert Rosen
Dalhousie University

From the Foreword by Robert Rosen:
"Dr. Savageau's work represents a fundamental contribution to the analysis and synthesis of biochemical control systems. An understanding of these control mechanisms lies at the very heart of the fundamental problems of biology and medicine, and in my view such understanding can only arise through the imposition of imaginative mathematical analysis on the empirical foundations. This is precisely what Dr. Savageau has done; I hope that his book will be widely read, and that it will have the influence it deserves."

INTERFACIAL ELECTROCHEMISTRY

An Experimental Approach

E. Gileadi, E. Kirowa-Eisner, and J. Penciner
Tel Aviv University

This is a good reference book for electrochemists and materials scientists interested in the kinetic processes that occur in the areas of corrosion, energy conversion using fuel cells, catalysis, and electroplating. It would also be useful to researchers interested in crystal growth and surface physics if they have the proper chemistry background. The authors correctly state that electrodics and irreversible processes are neglected in physical chemistry textbooks. They have done much to remedy the situation with their quite complete book.

INTERFACIAL PHENOMENA IN METALS AND ALLOYS

Lawrence E. Murr, *Department of Metallurgical and Materials Engineering, New Mexico Institute of Mining and Technology*
Foreword by Morris Cohen, *Department of Materials Science and Engineering, Massachusetts Institute of Technology*

"A hundred years of research on interfaces, from Gibbs to the present, is summarized in this useful work. Designed either as a reference or as a graduate text, it contains both problems and an extensive bibliography at the end of each chapter. The text is carefully referenced and illustrated with figures and photographs that have been borrowed from research journals, resulting in a very concrete and clear presentation. Murr has also prepared current tables of interfacial energies, which are not available elsewhere, and has included some unpublished data. The outstanding reputation of the author and his consulting editors is reflected everywhere in this unusually well-organized and well-written publication."

Spring books from Oxford

The Versatile Satellite

Richard W. Porter

This book reviews the historical background, the basic facts of satellite orbits and rocket propulsion, and the physical environment of near-earth space and its influence on the design of satellites. The author describes the diverse uses of satellites in communications, navigation, meteorology, earth and ocean observations, monitoring fresh-water resources, managing agriculture and forestry, and for various scientific and astronomical investigations. Finally he discusses Skylab and other manned vehicles, and speculates on the future applications of artificial satellites. Illustrated £4.95

A Shell Model Description of Light Nuclei

I. S. Towner

The goal of nuclear structure physics is to understand the properties of finite nuclei starting only with a knowledge of the free nucleon-nucleon interaction. This book traces the progress towards this goal. The early chapters discuss Hartree-Fock theory, Brueckner theory, and particle-hole models. The concept of effective interactions is introduced and applied to the spectroscopy of open-shell nuclei. A final chapter discusses the spectroscopic information derivable from direct nuclear reactions. £11 *Oxford Studies in Nuclear Physics*

Two-Phase Flow and Heat Transfer

Edited by D. Butterworth
and G. F. Hewitt

Two-phase flow is a phenomenon of importance in a wide variety of industrial plant, including boilers and nuclear reactors. This book covers gas/liquid two-phase flow, two-phase heat transfer, hydrodynamic instability, and condensation, finishing with a discussion of loss-of-coolant accidents in nuclear reactors. £14 *Harwell Series*

Module Theory

An Approach to Linear Algebra

T. S. Blyth

The aim of this text is to develop the basic properties of modules, and to show their importance in the theory of linear algebra. The first part deals with modules and vector spaces, and is suitable as an introductory undergraduate course; the second part deals with advanced linear algebra and is suitable as a final-year undergraduate or graduate text. £9.50

Beginning Model Theory

The Completeness Theorem and Some Consequences

Jane Bridge

Model theory is an important area of mathematical logic, and Gödel's Completeness Theorem and its corollary, the Compactness Theorem, form its core. This book concentrates on first-order predicate logic and a proof of the Completeness Theorem and its main consequences, and finishes with a selective introduction to model-theoretic applications of the results. £4.50 *Oxford Logic Guides*

Elements of Intuitionism

Michael Dummett

This book begins with a philosophical orientation and a sketch of the salient differences between intuitionistic and classical reasoning. The author outlines the intuitionistic approach to the theory of real numbers, in order to give the reader enough of a taste of actual intuitionistic mathematics to motivate the ensuing discussion of choice sequences and spreads, bar induction and the continuity principle, first-order intuitionistic logic, current results on completeness, and the philosophical issues surrounding an intuitionistic theory of meaning. £9
Oxford Logic Guides

Choice Sequences

A. S. Troelstra

This monograph presents a coherent and virtually complete account of the conceptual side of the theory of choice sequences, a theory which has already proved its value in mathematical research into intuitionism. An introductory chapter is followed by an extensive discussion of the motivation and the axioms for lawless sequences, the simplest case. The formal elimination of lawless sequences and the universes that can be constructed from them by continuous operations are then treated. £4.95
Oxford Logic Guides

Nuclear Sizes and Structure

Roger C. Barrett
and Daphne F. Jackson

A wide range of electromagnetic, strong, and weak interaction processes are here used to explain precisely which properties of the nucleus can be obtained from the various experiments, and to indicate the extent to which previously published parameters are really determined by the measurements as opposed to being merely consistent with them. The emphasis is on recent developments, both experimental and theoretical. £15

Texts for Advanced Undergraduates and Graduates

ELEMENTS OF QUANTUM THEORY

2nd edition, revised and enlarged

Frank L. Bockhoff, *Cleveland State University*

Review of first edition:

"This book is intended to initiate undergraduate chemistry students with very limited physics and mathematics backgrounds into the concepts and elementary applications of quantum mechanics. The author has gone to some pains to give a detailed development of those aspects of the subject that the beginner usually finds most difficult. The text divides roughly into two sections. The first half leads to a statement of the postulates and their application to the standard problems of particles in boxes and barrier penetration, and the second half treats the quantum description of atomic and molecular structure with emphasis on the hydrogen and helium atoms. The book's principle merit is its detailed exposition." — *Physics Today*

1976, xii, 334 pp., illus.
hardbound 0-201-00799-1 $17.50

INTERPRETATION OF MASS SPECTRA: An Introduction

2nd edition, revised, enlarged, reset

F. W. McLafferty, *Cornell University*

"This is an uncommon book. In addition to being a first-rate scientific document and text, it is a highly personal expression. Every page is colored by the author's enthusiasm, by his style in dealing both with chemical concepts and with his students and associates; it sometimes seems as though he is a part of his own subject matter . . . From the first page of the preface through the detailed solutions to unknowns, the book conveys McLafferty's sense of excitement and fun in working with mass spectra."

— *Journal of Chemical Education*

1973 (4th printing, with additional corrections, 1977), xx, 278 pp., illus.
paperbound 0-8053-7047-1 $8.50

INTRODUCTION TO CRYSTALLOGRAPHY

Donald E. Sands, *University of Kentucky*

"In a book written by a chemist for chemists, it is no surprise to find Crystallography considered a topic in Physical Chemistry. The first four chapters explain how structures are described. This is the backbone of the text: chemists obviously consider this material their main stumbling block. A second part, half as long as the first, tells how structures are determined. Granting the author his rightful choice of prerequisites, we would be hard put to improve his presentation."

— *The American Mineralogist*

1969 (2nd printing, with corrections, 1975)
xii, 165 pp., illus.
paperbound 0-8053-8473-1 $6.75

PROBLEMS IN SPECTROSCOPY

ORGANIC STRUCTURE DETERMINATION BY NMR, IR, UV, AND MASS SPECTRA

Barry M. Trost, *University of Wisconsin*

Review of first printing:

". . . The problems are difficult and challenging. Most of them require inferences from each of the available spectra for their solution. There are no reference tables of spectra so the problem solver must use other sources of data. This is an experience which closely parallels that encountered in solving a research problem.

"Certainly, the person who successfully works the problems in this book will be well equipped for the assignment of structures from modern spectroscopic data. The book seems most appropriate for advanced undergraduates and first-year graduate students."

— *Journal of Chemical Education*

1967 (2nd printing, 1977), xvi, 412 pp., illus.
paperbound 0-8053-9325-0 $13.50

Perspectivist tradition leads men of vision

J. D. Mollon

Theories of Vision from Al-Kindi to Kepler. By D. C. Lindberg. Pp. xii+324. (University of Chicago: Chicago and London, 1976.) £13.60.

In laboratories and coffee-rooms it is countless times debated whether a knowledge of the literature allows the scientist to stand on the shoulders of his predecessors or merely bestows on him a *damnosa hereditas*, fatally constraining his thought. The literature man scorns the rediscoveries and the omitted controls of his unread colleague: the latter argues that it is often faster to do the experiment than to find the answer in the literature and points to the low publication rate of the literature man.

Two of the greatest contributors to our understanding of visual perception, Thomas Young and Hermann Helmholtz, were literature men of enormous erudition whose systematisations too easily conceal from us the achievements of the eighteenth century. In his book, D. C. Lindberg argues that a third outstanding innovator in the theory of vision, Kepler, was not a revolutionary working in a vacuum but rather represents the culmination of the perspectivist tradition that extends back to the Islamic writers of the ninth and tenth centuries. He shows that Al-Kindi first made explicit the principle that luminous rays issue in every direction from every point on the surface of a luminous body and that Alhazen set the problem, that of establishing a one-to-one correspondence between points in the visual field and points on some plane in the eye. The pre-Keplerian solution was to assign an especial potency to those rays that were perpendicular to the surface of the cornea, that is, to those making up the visual cone, with its base on the object of vision and its apex at the centre of curvature of the cornea. (Lindberg does not notice that this theory is lent some truth by the Stiles–Crawford effect, the directional selectivity of the photoreceptors that favours rays normal to the retina). Kepler, equipped with the improved anatomy of Felix Platter and with his own understanding of the focusing properties of transparent spheres, was able to offer the correct solution, that the crystalline humour is not itself the seat of vision but in combination with the cornea serves to form an inverted image on the retina. But, Lindberg argues, the perspectivist tradition gave Kepler his problem, his facts, his methodological rules and his criteria of success. In this conclusion Lindberg explicitly opposes the standard view that Kepler transformed visual theory by mechanising it: "Kepler presented a new solution (but not a new kind of solution) to a mediaeval problem, defined some six hundred years earlier by Alhazen".

Lindberg himself is clearly a literature man by temperament. His impressive grasp of the primary Latin texts is complemented by a very wide knowledge of the academic literature: his book has over 1,000 footnotes to secondary sources. So it is understandable that he is unimpressed by Leonardo's contribution to visual theory. Leonardo was avowedly not a literature man and himself wrote: "If indeed I have no power to quote from authors as they have, it is a far bigger and more worthy thing to read by the light of experience, which is the instructress of their masters. They strut about puffed up and pompous, decked out and adorned not with their own labours but by those of others, and they will not allow me my own". Lindberg believes that Leonardo had read Pecham and Witelo but that his knowledge of the optical tradition was imperfect. Usually Leonardo did not work with Al-Kindi's principle of punctiform analysis but rather thought of the species, or image, of an object as radiating holistically. His understanding of the formation of images by reflection and refraction was limited. It is particularly curious that this skilful anatomist was so weak in ocular anatomy: he confounded the vitreous and the crystalline and supposed that the eye consisted of two concentric spheres. By reading any of the mediaeval perspectivists he would have been furnished with a more sophisticated account. Lindberg is mistaken, however, in admonishing Leonardo for claiming that the apparent size of objects increases with the size of the pupil: there is a clear basis for this observation in the phenomenon of irradiation. Leonardo's *explanation* is another matter, but it is noteworthy that his claim about the effect of pupillary size is contained in the same manuscript (F of the Library of the Institut de France) as his observation that a uniform iron rod heated only in part of its length will appear considerably larger in its heated part. The latter phenomenon is primarily a consequence of irradiation.

The theory of optics and vision was central to mediaeval philosophy and provided a link between physics, medicine and theology. Optics was, for example, fundamental in Bacon's planned synthesis of all human knowledge. Lindberg's book should therefore be of interest to mediaeval historians in general. He draws attention, for example, to the neglect of the history of the translations from Greek and Arabic to Latin in the twelth century: almost nothing is known of the purposes and motivation of the translators, of the selection of works or of the mechanics of translation; and towards the further understanding of this crucial movement, Lindberg provides a detailed Appendix on the translation of optical works.

The book is illustrated with many diagrams of the eye drawn from ancient and mediaeval authors. Man's idealised representations of his own visual organ serve nicely to illustrate how his perception is influenced by his conceptual framework. Perhaps we can never accurately perceive a biological mechanism until we have constructed the artefact that will serve as a model: we must have lenses before we can perceive the eye as an image-forming device and computers before we can perceive the brain as an information-processing machine. What is regrettable is that Lindberg nowhere includes an accurate modern diagram of the eye, an inclusion that would have been invaluable to the general reader trying to follow mediaeval discussions of whether there are four tunics or seven, three humours or two.

To reduce his material to manageable proportions, Lindberg omits discussion of theories of the physiology and psychology of vision. To some extent this exclusion is artificial, for it is clear that many of Kepler's predecessors (including Leonardo) were held back from the correct solution by explicit reluctance to entertain an inversion of the image; and Kepler himself acknowledged that he "dutifully tortured" himself "in order to show that the cones intersecting when they pass through the aperture of the uvea intersect again behind the crystalline, in the middle of the vitreous humour, so that another inversion is produced." But he protested that geometry allowed no escape from an inverted image and thereby bequeathed to his own successors a new and peculiarly vexatious problem. ☐

J. D. Mollon is Lecturer in Experimental Philosophy at the University of Edinburgh, UK.

Mental imagery

John Krebs

The Question of Animal Awareness. By D. R. Griffin. Pp. viii+135. (Rockefeller University: New York, 1976.) $8.95.

GRIFFIN'S thesis is that animals experience mental images and therefore a primitive form of awareness. One could argue about the meaning of these words and their relationship to the more strictly human experiences of subjective emotions and self-awareness, both of which are specifically excluded from Griffin's definitions. But since it is easy to see roughly what Griffin is getting at, I think such a philosophical argument is superfluous. Much of the book is filled with the 'evidence' for animal awareness, and although the style is clear and concise, I feel that Griffin makes an unnecessarily elaborate case: most behavioural biologists are quite ready to accept the idea that animals have mental images of events or objects in their environment.

The main points of Griffin's thesis are as follows. First, he establishes, with a few examples—such as bats catching their prey by sonar and birds orientating by star compasses—that animals are rather more complex than might have been supposed 50 years ago. Especially remarkable are the linguistic abilities of chimpanzees and honey bees. Chimps, such as Washoe, can construct sentences in American Sign Language, showing that they understand a few rules of human language, and bees use an arbitrary communication system for encoding information about remote feeding places.

Griffin sees the complexity of animal language as important, because so much of man's mental experience is dependent on language. (As an aside, the chimp and bee examples are always quoted as evidence for the complexity of animal language: chimps one can understand, but bees seem to be an anomaly. Either they are an evolutionary freak, or we are waiting for more scientists of von Frisch's genius.) In fact, the complexity of animal language does not seem to be a crucial part of Griffin's thesis, since some of the clearer examples of mental imagery in animals—for example, 'searching images'—do not involve complex language.

Another line of evidence used by Griffin is neurophysiological. He revives the argument that the nervous system of man is only quantitatively different from that of animals, so products of the nervous system such as awareness should also differ only in quantity. This assumes, of course, that quantitative differences are not translated by thresholds into qualitative effects.

Finally, Griffin argues on evolutionary grounds that mental awareness has survival value in allowing an animal to anticipate and cope with complex problems, so it should be favoured in all animals by natural selection. Interestingly, Griffin does not use dreaming in animals as evidence for mental imagery, although all dog-watchers will agree that dogs dream about chasing the cat next door.

Whether or not they accept the individual steps in his argument (most of which are not new), most behavioural biologists will concur with Griffin's overall thesis. Equally, I feel that most will be disappointed with Griffin's answer to the "so what?" question. The test of the value of any scientific hypothesis is whether or not it generates new experiments, and it seems to me that the awareness hypothesis fails this test.

Griffin argues, by analogy with man, that the only way to find out about an animal's mental experiences, it to ask it directly, or indirectly, what is it thinking about. With Washoe this might be done through American Sign Language, with bees and birds through life-like dummies or models. If one leaves out the special case of Washoe and his clan, what it boils down to is a plea for more work on animal communication. This is an uncontroversial proposition, but if I try to think up experiments or observations to elucidate the meaning of, for example, the incredibly complex song of a skylark, is the hypothesis that larks have mental experiences going to help me? ☐

John Krebs is Lecturer in Zoology at the Edward Grey Institute of Field Ornithology, University of Oxford, UK.

a revolution in the theory of gravitation

A NEW RELATION BETWEEN THE VELOCITY OF LIGHT and PLANETARY MOTIONS

discovered by

MORRIS REDMAN SPIVACK

PART II of

$$G = \frac{Mm \quad c}{r^2}$$

(A revision of NEWTON'S LAW)

(5th EDITION—JAN., 1977)

Abstract:

1. GRAVITATION transfers energy from one body to another with the velocity of light. The relative intensity of the field controlling the orbit may therefore be expressed as a proportion of the velocity of light depending on the radius between the bodies.

2. In the case of the non-periodic advance (excess motion) of the perihelia of any planets — if the excess motion be known (as it is in the case of MERCURY), then dividing the excess motion by the observed mean orbital motion will give a PROPORTION of the RECIPROCAL of the velocity of light (as pure number) which can be obtained *independently* when the non-periodic advance is *not* known (for example in the case of MARS).

3. The MEAN MOTION when multiplied by the proportion of the reciprocal of the velocity of light ("c") thus independently obtained, will ALWAYS give us the EXCESS MOTION — and vice versa as at (2) above.

4. The METHOD of obtaining the correct proportion of "c" independently and directly from relativistic principles is demonstrated herein.

5. A new relation between the velocity of light and planetary motions is thus established, which may be useful in solving other problems of illimitable range and most certainly lead to the discovery of other important relationships and equivalencies in relativity.

4pp., unbound folio, litho, £1 or $2, by sea mail (in the ORIGINAL STAMPED BOARDS, £5 or $10.)

Brain anatomy

J. Z. Young

The Vertebrate Brain. By R. Pearson and L. Pearson. Pp. xi+744. (Academic: London and New York, 1976.) £23.

THE great expansion of interest in neuroscience in recent years has not been accompanied by an equivalent interest in comparative neurology. Microscopists and experimentors have indeed used neurones from very diverse animals, but few have tried to investigate their specific adaptive features in relation to the environment. Still fewer have tried to follow the course of evolution of the brain throughout the vertebrate phylum. The only comprehensive work on the subject is that of Kappers, Huber and Crosby written in 1936. The leading living expert in the field in Hans Kuhlenbeck, whose major work is still appearing. One looks therefore with excitement at a new book on *The Vertebrate Brain*. The authors' aim is to provide "a survey of the anatomical, biochemical and physiological aspects of the vertebrate brain". They believe that the development of the neurosciences "will probably prove as profound in their effects on man and his philosophies as did the concepts of nuclear physics during the 1930s or the 'molecular biologists' of the 1950s".

This may turn out to be so, but unfortunately the data that they have collected certainly do not provide a sufficient basis for such a revolution. The function of the nervous system is to process "information", but this word does not occur in the index, nor does "code" or "representation", or indeed "action potential," "electroencephalogram", or most of the terms of neurophysiology. We shall only be able to compare different brains when we have developed adequate ways of analysing how complex masses of nervous tissue process information.

What the present authors have done is to make a survey of some aspects

Chapman & Hall

The Scientific division of Associated Book Publishers Ltd,
11 New Fetter Lane, London EC4P 4EE.

Titles marked * are distributed in the USA by Halsted Press,
a division of John Wiley, 605 Third Avenue, New York, NY 10016.

*Plant Viruses 6th edition

K. M. SMITH

This sixth edition of Plant Viruses not only incorporates all new developments but also includes a chapter on an entirely new group of micro-organisms, the mycoplasmas, discovered in recent years, which cause many of the diseases previously attributable to viruses. The comparatively new field of algal and fungal viruses is also discussed and modern technical developments, such as tissue and cell culture of viruses are described.

14th April 1977: £5.50. Science Paperback: £3.25.

*Asthma

Edited by T. J. H. CLARK and S. GODFREY

This book is intended to be a contemporary summary of our knowledge regarding asthma both from the viewpoint of the origins of the disease and its treatment. The book assembles leading authorities from the United Kingdom to give a detailed account of asthma, and the range of authors has enabled the subject to be covered comprehensively, authoritatively and in a readable way.

12th May: £10.00.

OUTLINE STUDIES IN BIOLOGY SERIES
General Editor: J. M. ASHWORTH

We believe that the *Outline Studies in Biology Series* represents the only sensible answer to textbook publishing for a whole range of new topics in university and college biology curricula.
The individual books in the *Outline Studies in Biology Series* present succinct, authoritative and up-to-date introductions to their subject. They supplement and extend the main course texts, and because each book deals with only one topic the series offers the advantage of great flexibility of use.

*Enzyme Kinetics

P. C. ENGEL

This book emphasises the importance of enzyme kinetics to understanding how enzymes function under various conditions. It is especially written for those students who find detailed mathematics an obstacle to understanding this subject.

12th May 1977: £1.75.

*Insect Biochemistry

H. H. REES

In addition to outlining the most distinctive features of the biochemistry of insects, this book draws attention to the way in which insects have adapted or evolved to cope with their particular environment.

12th May 1977: £1.50.

Outstanding Books of the Year

MOLECULAR ANTHROPOLOGY
Genes and Proteins in the Evolutionary Ascent of the Primates

edited by **Morris Goodman**
Wayne State University School of Medicine
and **Richard E. Tashian**
University of Michigan Medical School
Associate Editor: **Jeanne H. Tashian**
University of Michigan Hospital

Explores some of the major issues and controversies surrounding the subject of molecular anthropology—a relatively new discipline concerned with the study of primate phylogeny and human evolution through the analysis of genetic information contained in proteins and polynucleotides. A volume in the Advances in Primatology series, **W. Patrick Luckett** and **Charles R. Noback,** editors.
466 pp., illus., 1977, $42.00/£22.05

BIOMEDICAL APPLICATIONS OF IMMOBILIZED ENZYMES AND PROTEINS

edited by **Thomas Ming Swi Chang**
McGill University

This two-volume work provides a comprehensive survey of the state of research on the uses of immobilized enzymes and proteins in medicine. The first volume is devoted to the multiplicity of current and future therapeutic applications; the second volume discusses the applications and prospects for immobilized enzymes and proteins in diagnosis and public health, as well as preventive medicine.
Volume 1: approx. 475 pp., illus., 1977, $53.40/£28.04
Volume 2: approx. 400 pp., illus., 1977, $47.40/£24.89

COMPREHENSIVE VIROLOGY

edited by **Heinz Fraenkel-Conrat**
University of California at Berkeley
and **Robert R. Wagner**
University of Virginia

This interdisciplinary treatise, published in approximately 25 volumes, is the first encyclopedic analysis of the current information explosion in animal, plant, and bacterial virology.

Volume 7: Reproduction: *Bacterial DNA Viruses*
300 pp., illus., 1977, $30.00/£15.75
Volume 8: Regulation and Genetics:
Bacterial DNA Viruses
350 pp., illus., 1977, $35.40/£18.59
Volume 9: Regulation and Genetics:
Genetics of Animal Viruses
approx. 695 pp., illus., 1977, $59.40/£31.19
Volume 10: Regulation and Genetics:
Viral Gene Expression and Integration
approx. 530 pp., illus., 1977, $47.40/£24.89
Volume 11: Regulation and Genetics: *Plant Viruses*
approx. 325 pp., illus., 1977, $35.40/£18.59

THE YEAR IN ENDOCRINOLOGY
1975-1976

edited by **Sidney H. Ingbar, M.D.**
Director, Thorndike Laboratory of Harvard Medical School at the Beth Israel Hospital

A new, comprehensive annual series that provides the reader with a broad authoritative review of the important developments in the major areas of endocrinological research.
327 pp., 1977, $27.00/£14.18*

THE YEAR IN METABOLISM
1975-1976

edited by **Norbert Freinkel, M.D.**
Director, Center for Endocrinology, Metabolism, and Nutrition
Northwestern University Medical School

Introduces a major new annual series in which the developments of the previous year in eleven broad areas of metabolism are reviewed by internationally recognized experts.
353 pp., 1977, $27.00/£14.18*

$47.40/£24.89 for combined order for *The Year in Endocrinology* and *The Year in Metabolism*

PHOTOCHEMICAL AND PHOTOBIOLOGICAL REVIEWS

edited by **Kendric C. Smith**
Stanford University School of Medicine

Documents and interprets past developments, recent advances, and possible areas of further study in the fields of photochemistry and photobiology.
Volume 1: 391 pp., illus., 1976, $39.00/£20.48
Volume 2: approx. 335 pp., illus., 1977, $35.40/£18.59

HUMAN EMOTIONS

Carroll E. Izard
University of Delaware

Explores how emotions form an integral part of human consciousness, cognition, and action through analyses of both theoretical and empirical research. A volume in the Personality, Psychopathology, and Psychotherapy series, **Carroll E. Izard** and **Jerome L. Singer,** editors.
approx. 480 pp., illus., 1977, $30.00/£15.75

THE TOKEN ECONOMY
A Review and Evaluation

Alan E. Kazdin
The Pennsylvania State University

A critical and comprehensive review of the use of token economies in behavioral modification therapy, this important work evaluates the advantages and limitations of this controversial treatment modality. A volume in The Plenum Behavior Therapy Series, **Nathan H. Azrin,** editor.
342 pp., illus., 1977, $20.34/£10.68

TREATMENT AND REHABILITATION OF THE CHRONIC ALCOHOLIC

edited by **Benjamin Kissin** and **Henri Begleiter**
Downstate Medical Center of the State University
of New York

Presents the whole range of treatment approaches in long-term rehabilitation of the alcoholic. The multiplicity of proposed therapies, each strongly defended by its proponents, points to the major difficulty in treating alcoholics—that alcoholism is a complex medical-social syndrome requiring an integrated therapy. Volume 5 in The Biology of Alcoholism series, **Benjamin Kissin** and **Henri Begleiter**, editors.
658 pp., 1976, $47.40/£24.89

HANDBOOK OF TERATOLOGY

edited by **James G. Wilson**
The Children's Hospital Research Foundation
and University of Cincinnati
and **F. Clarke Fraser**
McGill University and The Montreal Children's Hospital

This authoritative four-volume treatise offers a definitive, integrated source of facts, concepts and methods in the broad field of teratology.

Volume 1: General Principles and Etiology
476 pp., illus., 1977, $46.80/£24.57*
Volume 2: Mechanisms and Pathogenesis
approx. 480 pp., illus., 1977, $46.80/£24.57*
*Not available from Plenum in Japan and Okinawa.

TOPICS IN COGNITIVE DEVELOPMENT
Volume 1: Equilibration: Theory, Research, and Application

edited by **Marilyn H. Appel**
Medical College of Pennsylvania
and **Lois S. Goldberg**
Glassboro State College

This volume, featuring Jean Piaget's famous paper on equilibrium, inaugurates a new series devoted to the theoretical, empirical, and applied aspects of Piaget's epistemology. A publication of the Jean Piaget Society.
approx. 200 pp., illus., 1977, $22.20/£11.66

PROTEIN METABOLISM OF THE BRAIN

A. V. Palladin, Ya. V. Belik, and **N. M. Polyakova**
Academy of Sciences of the Ukranian SSR
Translated from Russian by **Basil Haigh**
Translation edited by **Abel Lajtha**

Giving equal emphasis to the structural, dynamic, and functional approaches to brain biochemistry, this comprehensive book reviews both the development of, and the most recent advances in, brain protein research—a rapidly developing field essential for a complete understanding of the neurobiology of brain function. A volume in the Studies in Soviet Science—Life Sciences series.
335 pp., illus., 1977, $42.00/£22.05

FEAR OF SUCCESS

David Tresemer

Focusing on the current controversy surrounding the "fear of success" theory used to explain women's unequal attainments in the modern occupational structure, the author probes fundamental questions about motivation and the nature of the psyche in a social setting.
approx. 220 pp., 1977, $17.94/£9.42

PEPTIDES IN NEUROBIOLOGY

edited by **Harold Gainer**
National Institute of Child Health and Human
Development, Bethesda, Maryland

Critically and comprehensively analyzes a new and exciting area of research in the neurosciences—the role of peptides in the regulation of neuronal activity, the mediation of many higher brain functions, and the control of behavior. A volume in the Current Topics in Neurobiology series, **Samuel H. Barondes** and **Floyd Bloom**, editors.
approx. 440 pp., illus., 1977, $41.40/£21.74

BIOLOGY OF THE UTERUS

edited by **Ralph M. Wynn**
University of Illinois at the Medical Center

This important work—the only book currently available that deals with both basic biology and clinical aspects of the uterus—correlates classical histology and embryology with biophysics, ultrastructure, and biochemistry, relating these topics to the clinical problems of ovarian-uterine relationships and to the onset of labor.
748 pp., illus., 1977, $66.00/£34.65

THE PROSTAGLANDINS
Volume 3

edited by **Peter W. Ramwell**
Georgetown University School of Medicine

Reflecting the rapid progress in biomedical research, this volume examines the most recent developments in research into the relationships between prostaglandins and physiological functions such as digestion and respiration.
approx. 350 pp., illus., 1977, $47.40/£24.89

COGNITIVE-BEHAVIOR MODIFICATION
An Integrative Approach

Donald H. Meichenbaum
University of Waterloo, Canada

Helps to bridge the gap between the clinical concerns of cognitive-semantic therapists and the technology of behavior therapy by offering a new integrative, empirical account of the mechanisms of change involved in any therapeutic procedure. A volume in The Plenum Behavior Therapy Series, **Nathan H. Azrin**, editor.
approx. 300 pp., illus., 1977, $17.94/£9.42

Systemic Fungicides
Second edition
Edited by R W Marsh

The first edition of this highly successful book was published in 1972. Since then there has been a massive increase in the production and utilisation of systemic fungicides. These developments are reflected in this new and enlarged edition, which assembles the contributions of sixteen authors from the UK, USA and the Netherlands. Each of the authors is an acknowledged authority in a specialised field of fungicide studies.

Tropical Pasture and Fodder Plants
A V Bogdan

This is a unique and valuable source of reference for all those concerned with agriculture, animal husbandry, ecology and soil science in tropical areas. Over 300 species of grasses and legumes are described in alphabetical order of botanical names. The information given on the more important plants includes: botanical and common names; climate and soil requirements; establishment; management; fertilising; yields; chemical composition and nutritive value; reproduction; and much more.
In the *Tropical Agriculture Series.*
Cased £17.00 net

The Oil Palm
Second edition
C W S Hartley

Since the first edition was published, the oil palm has developed faster than any other tropical plantation crop. This second edition covers all aspects of its growth and exploitation. A full description of the botany of the crop is given, together with details of the research carried out on oil palm physiology, selection and breeding, the climate and soils suitable to its culture, methods of cultivation, nutrition, pests and diseases, and the extraction of palm oil and kernels by village and industrial methods.
Available soon.

Pleistocene Geology and Biology
Second edition
R G West

This general account of the geology and biology of the Pleistocene will be invaluable to students of geography, archaeology, geology and biology. In this second and updated edition, Professor West provides a chapter by chapter account of various aspects of Pleistocene environments and life. This includes glacial geology, periglacial phenomena, sea-level change, climatic change, dating, investigations in the field, and plant and animal life. The final chapters deal in some detail with the Pleistocene of the British Isles.

Longman

Circle No. 21 on Reader Enquiry Card.

of the literature of the classical comparative anatomy of the cell masses and tracts in different vertebrate brains. It is a formidable problem, indeed, to know how to present this knowledge. The authors have decided to take each part separately. So we go through the details of the medulla from Agnatha to Mammals and then start on the cerebellum, and so on. It is not the authors' fault that such a division makes for difficulties in following particular functional systems. In some parts it works well—for instance, the mid-brain roof—but it is disastrous for the reticular system, which is scattered all through the book, and it does not work well for the forebrain.

No-one has discovered the principles with which knowledge about the structure and functioning of various nervous systems can be compared. The authors' brave attempt provides some of the facts and the stimulus to attack the problem. ☐

J. Z. Young is Emeritus Professor of Anatomy at University College, London, UK.

Perceptual exploration

Stuart Sutherland

Cognition and Reality. By U. Neisser. Pp. xiii+230. (Freeman: San Francisco and Reading, 1976.) £3.70.

In 1967, Neisser published a book called *Cognitive Psychology*: it was a vigorous and clear account of that subject which marked its coming of age. The book was optimistic and gave the impression that we would eventually come to understand the workings of the mind in terms of the information processing operations it carries out. In *Cognition and Reality,* Neisser seems to have become somewhat disillusioned with the progress of the cause he espoused ten years ago. Workers in the field, he claims, are trapped in specific experimental paradigms; they fail to tap the true potential of the human mind since they use unpractised subjects and artificial tasks; their work has little bearing on real life situations and does not tell us what mind or consciousness really are.

Neisser's own solution to the problem of cognitive psychology takes the form of a shot-gun marriage between J. J. Gibson and F. C. Bartlett. To understand the mind, we must first understand the world in which people live: in particular we must understand the relationship between the information available to our senses and the external world specified by that information. The information we "pick up" depends on our internal schemata: they guide perceptual exploration and are in turn modified by it. Perception is not an instantaneous happening but an ongoing interaction between our schemata and the world. "Images are not pictures in the head, but plans for obtaining information from potential environments".

The book makes some cogent points even if they are often incidental to the main theme. For example, Neisser points out that except in a very constrained environment where people have few choices, we shall never be able to exert behavioural control over other people: to do so, we would need to have a complete understanding not only of them, but also of the world in which they live. We cannot predict, let alone control, the moves a master chess player will make unless we have at least as much knowledge of chess as he does. Elsewhere, Neisser exposes some of the crudities of earlier theories of cognition. He has himself shown, amongst others, that with sufficient practice it is sometimes possible to carry out two complex tasks at once: the brain is not in any obvious sense a limited capacity channel.

Cognition and Reality is not an easy book to understand or to evaluate. First, it is unclear how far Neisser is putting forward a new thesis rather than merely using a different terminology. Nor is it obvious whose views he is attacking. There is a good deal of verbal fencing: for example, he registers his objection to the idea that the mind *processes* information by writing: "The information itself is not changed, since it was in the light already. The schema picks it up, is altered by it, uses it". Second, his exposition of the operation of schemata remains at a very general level and he is curiously reluctant to give examples of how his ideas can explain any phenomena in detail. When he does attempt explanation, as, for example, in his discussion of the perception of emotional expression in others, the explanations are at such a general level that it is hard to see whether any new light has been thrown on the problem.

At times one may even suspect that the constant flourishing of the magic word "schemata" serves more to distract attention from the phenomena to be explained than to explain them. Although the status of Neisser's central thesis remains unclear, the book deserves to be widely read if only for the interesting and acute observations that are scattered through its pages. ☐

Stuart Sutherland is Director of the Centre for Research on Perception and Cognition at the University of Sussex, UK.

BMJ BOOKS

STATISTICS AT SQUARE ONE

by T. D. V. SWINSCOW
from the British Medical Journal
2nd Edition — March 1977

The statistical testing of data is indispensable in many types of medical and biological investigation. This book provides step-by-step instruction on the use of statistical tests. Subjects covered include standard deviation, Chi-Square tests, t tests, non-parametric tests, product-moment and rank correlation, and Fisher's exact probability test. Methods are specially adapted to pocket calculators.

"The ability to put symbols in sequence may well be one of the greatest advances in man's development . . . This excellent and attractive volume will give you an idea into which category an article or projected article fits. The ink you save may be your own. It is superb value."
O'Donnell, Barry, *British Medical Journal*, 1977, 1,451.

". . . the reader is introduced to the most important statistical concepts in a concise, straightforward manner. Dr. Swinscow's commonsense approach to his subject is outlined in the introduction. . . ."
Murray, J. J., *British Dental Journal*, 1977, 142,81.

Technology and food production

C. R. W. Spedding

Food Production and Consumption: The Efficiency of Human Food Chains and Nutrient Cycles. Edited by A. N. Duckham, J. G. W. Jones and E. H. Roberts. Pp. xx+541. (North-Holland: Amsterdam and Oxford, 1976.) Dfl.120; $48.95.

THIS is a bold and ambitious book that deserves to be treated as a serious attempt to encompass in one volume the entire food production system of the world, from photosynthesis to marketing and consumption. Rigorous criticism is therefore a better use of limited reviewing space than mere description of contents. The latter can be summarised as being organised into 28 chapters (by 31 authors) in five parts (introduction; ecological aspects; biological components; social and economic aspects; a strategic synthesis). The book is well produced and edited, and relatively free from minor errors.

The quality of the individual contributions is inevitably uneven but as a compilation of basic facts the book is extremely valuable, although more could usefully have been included on, for example, the inefficiencies of animal populations and nitrogen fixation in plants. The enterprise, however, was intended as much more than a compilation; what has to be assessed, therefore, is the success of the synthesis achieved.

Energy is used as "the major currency" and, although the arguments are strong, it is perhaps rash to base a total synthesis too heavily on this alone. It is argued that the value of land depends largely on its ability to derive an income from solar energy. The world is, however, full of exceptions to this: the very ability referred to is dependent on other inputs with costs that have to be justified by probable profit and this is often not related at all to current energetic efficiency.

Furthermore, there are dangers in regarding food as merely a biological necessity. Space, water and oxygen are also biological necessities, but who would accept an argument based on providing the minimum biological requirements for these necessities? If man wants more than the minimum out of life, 'better' food would seem at least as reasonable an optional extra as cars, bingo or television.

Indeed, the book recognises that there is little hope of diverting cereals from livestock even though this could result in more food being available. The question of "available to whom?" remains a worrying one. The confidence generated by the conclusion that there are "no insuperable biological problems in feeding the world up to 2000 AD" evaporates somewhat when it is realised that both hunger and overconsumption now exist independently of technical knowledge, even when applied.

The conclusion that food systems are extremely inefficient is well documented but there is, in my view, too little emphasis on the problems of tackling such inefficiency. Identifying a problem has to be followed by selection, from all the technical possibilities, of an appropriate solution.

Although a systems approach is advocated, the book is mainly based on an examination of food chains—linear linkages without feedbacks. The editors recognise this but do not greatly emphasise that, when governments are recommended to focus on particular inefficiencies, they should do so with due regard to all the consequences. The difficulties of doing this ought to be amongst the reasons for the modelling activity recommended.

It will certainly be necessary, as is strongly argued, to aim at high yields *without* high inputs of support energy, but this may not be sufficient. No-one would quarrel with the conclusion that "the greatest potential improvement thus lies in the area of conventional agricultural technology", but this is always likely to be so in the short term (if we mean by improvement greater food production). But if much more food was grown and harvested, the dilemma would remain, that the hungry people are also desperately poor.

Despite these criticisms, this volume is a constructive step in the right direction and will be of great value to all those interested in the application of technology to efficient food production.

C. R. W. Spedding is Professor of Agricultural Systems and Head of the Department of Agriculture and Horticulture at the University of Reading, UK.

Foresight and responsibility in land use

John Andrews

The Thames Transformed: London's River and Its Waterfowl. By J. Harrison and P. Grant. Photographs by P. Harrison. Pp. 240 (André Deutsch: London, 1976.) £5.95.

INDUSTRIALISED British estuaries have recently begun to receive the attention necessary to retain or restore their natural productivity. The Thames exemplifies the work, its results and the complex problems to be solved if the international importance of wildlife in our major estuaries is to be maintained.

One-third of *The Thames Transformed* deals with the inner estuary, describing well the decline of water quality to the point where the river was a deoxygenated broth in which neither bird, fish nor weed could persist, and outlining the remarkable work of the London County Council/Greater London Council and the Port of London Authority in restoring reasonable conditions in which wildlife could return. Ironically, continued improvement has now reduced the massive *Tubifex* population on which the wildfowl feed, so that their numbers are declining, whereas waders have lost feeding areas due to reclamation.

The authors are experienced amateur ornithologists, Jeffery Harrison being known particularly for work on wildfowl and his concern for the north Kent marshes. Nearly half the book is devoted to this area—the Essex shore is dismissed in a cursory eighteen pages—and deals almost exclusively with wildfowl, including detailed historical accounts of occurrences. There is no discussion of the ninety-thousand waders or other bird populations, nor of the botanical, entomological and other important scientific features of the outer estuary. Concentration on the wildfowl produces recommendations about the agricultural management of the marshes which are not in the best interests of the total biological resource, whereas the conflict between wildfowl—particularly brent—and farmers, is glossed over. The identification of current industrial and recreational threats is valuable but too brief to demonstrate fully the complexity of the problems, both from the point of view of the 'developer' faced with real social and economic issues, and of the 'conservationist' striving to maintain scientific interest.

The authors suggest that the north Kent marshes should become a National Park rather than a National Nature Reserve, perhaps because the Nature Conservancy Council (NCC) has never had the finance required. Indeed, the money for research and land acquisition which resulted from the Maplin Airport threat, were gained for NCC by the voluntary bodies which fought the Bill at Committee stage. It seems odd that there is no mention of this and some other important milestones, including the establishment of the NCC/Ministry of Defence Advisory Committee on Foulness and of the Thames Estuary Wildlife Conservation Group. The authors do give credit, however, to the conservation efforts of the PLA, the Central Electricity Generating Board, and others. By encouraging them, their book can only help conservation which depends so much on the foresight and responsibility of all involved in land-use decisions. ▣

John Andrews is Head of the Conservation Planning Department of the Royal Society for the Protection of Birds, dealing with land-use issues affecting birds throughout the UK.

Baffling disease

C. H. Andrewes

Influenza: The Viruses and the Disease. By Sir Charles H. Stuart-Harris and G. C. Schild. Pp. x+242. (Arnold: London, 1976.) £12.

THE remarkable properties of the causative virus have made influenza a most fascinating yet baffling disease. Despite a vast amount of work there is still much to learn, particularly about how the infection can be controlled. Stuart-Harris and Schild's book is packed with information. For much of his working life, Sir Charles Stuart-Harris has been involved with the disease; he has in particular cultivated the area in which clinical and laboratory medicine overlap. Dr Schild was until recently in charge of the WHO World Influenza Centre at the National Institute for Medical Research, London, UK. Each of 12 chapters is followed by a list of references varying in number from 40 to over 100. Even these, as the preface points out, represent only a selection from the vast world literature.

We have first an outline of "the modern history of the study of the causes of human influenza". The authors pay only brief attention to work preceding the discovery, in 1933, of the susceptibility of ferrets to infection. Indeed there is only passing mention of Pfeiffer's so-called influenza bacillus, *Haemophilus influenzae*. Nor is much space devoted to outbreaks in earlier years, for the identity of the infecting agent of those times can only be inferred. Even the catastrophic 1918–19 pandemic is not considered at length.

Having reviewed the most important laboratory findings, including transmission to animals, cultivation and interference, chapter 2 discusses in great detail the molecular biology and replication of the virus. There are many excellent and well reproduced electron micrographs. These depict the whole virus and its separated components, and are supplemented by diagrams clearly explaining the structure and mode of replication of the virus.

Description of the viral antigens leads on to discussion of virus variation, the minor changes known as 'antigenic drift' and the periodical major 'antigenic shift' that herald pandemics. We learn how two viruses growing together in culture or in living animals may exhibit recombination of characters, resulting in viruses with hybrid properties.

Chapter 4 deals with the influenza viruses of swine, horses, birds and other species; for it is now recognised that man is only one host of a versatile family of viruses. There is increasing interest in the possibility that new pandemic strains may arise from recombination between human and animal viruses. The authors are, however, very cautious and write: "At the present time is seems somewhat premature to assess the significance of these findings . . .".

Chapter 5 describes the disease in man and its complications. We then have two chapters on epidemiology, with numerous diagrams illustrating the variations in mortality and morbidity from year to year. The authors admit to being puzzled as to where the virus goes between outbreaks and why older viruses disappear when new antigenic variants appear. There are full references to the work that led to the doctrine of "original antigenic sin". This concerns the remarkable fact that a person's first experience of a virus determines the pattern of his subsequent antibody responses: these are largely directed against the virus he first encountered rather than against more recent ones. When tests are made in the light of this, against various animal viruses, all sorts of intriguing questions arise about the nature of the influenza viruses involved in outbreaks of earlier years.

Studies of immunity, next described, deal largely with the relation between immunity and the level of antibodies in serum and in nasal secretions. Clearly it is vital to understand these matters if vaccination is to be attempted with any success. The results of several trials with inactivated vaccines of various kinds are reviewed in detail, and there is discussion about the best strategy for vaccine administration.

There are obvious theoretical advantages in the use of a live attenuated vaccine: it can be given as a spray and thus be much more acceptable; and it would be vastly cheaper. Methods used for virus attenuation are described together with the results of trials; those on a large scale have been carried out mainly in the USSR and Jugoslavia. It seems that, although acceptably attenuated vaccines are available, the results of trials have been variable. The authors suggest that live vaccines are more likely to be effective "when a new pandemic virus is triggering off a new cycle of epidemics". Otherwise, killed vaccines may be better.

"Some progress" is reported in the field of chemoprophylaxis and chemotherapy. Amantidine, in particular, is discussed, as is the theoretical basis of the ways in which drugs may contrive to upset replication or release of virus.

The final chapter provides details of the various techniques in use for the isolation and assay of virus, and of the various serological methods in use. Particularly useful will be the accounts of the recently described "single-radial-immunodiffusion" and "single-radial-haemolysis" tests.

A postscript discusses the recent excitement over the small outbreak due to a swine-like virus in New Jersey. As is wisely pointed out, "spread of swine influenza viruses from pig to man and their restricted spread in the population may have occurred from time to time in the past without detection".

The book will be of great value to workers in this field and to those concerned with preventive measures. It invites comparison with another, much smaller, popular book on the subject, *Influenza, the last great plague* by Professor W. I. B. Beveridge (Heinemann Educational: London, £2.95). Stuart-Harris and Schild's book is full of well documented facts, but the authors are very chary of even modest speculation. Not so, Professor Beveridge; he freely discusses pandemics from 1700 onwards, considers the birth of pandemics, and seems to have little doubt about the role of animal viruses in their genesis. Whereas one book describes the "trees" in most valuable detail, the other makes a bold attempt to discern the nature of the "wood".

The only serious criticism of Stuart-Harris and Schild's book is that the print is annoyingly smaller than usual; doubtless the price would otherwise be even higher. One hopes that the rising cost of books will not cause publishers to lower their standards of presentation.

Sir Christopher Andrewes was Deputy Director of the National Institute for Medical Research, London, UK, from 1952–61, during which time he was also in charge of the WHO World Influenza Centre.

Climatic pipe dreams

R. P. Pearce

The Cooling. By G. Ponte. Pp. 306. (Prentice-Hall: Englewood Cliffs, New Jersey, 1976.) $8.95.

THE author of this book is described on the fly-leaf as having been an arms control researcher and who has since worked as a television and radio commentator. The book is about world climatology, its scientific as well as its wider human aspects. I, the reviewer, am a meterorologist who has spent a large part of his life in a University environment, attempting to solve some of the enormously difficult scientific problems which the atmosphere poses, of which those relating to longer-term climatic changes on the global scale are perhaps the most challenging of all.

I can only describe the experience of reading this book as having been something resembling a meteorological nightmare. Such a hostile instinctive reaction to a book makes it difficult for any reviewer to present what he feels he will regard in retrospect as a fair and reasoned appraisal, and I will therefore make every effort to give the author as much credit as it seems possible to give him, bearing in mind the highly controversial nature of the topic on which he has chosen to write.

The first part is an account of existing knowledge of climatic trends, particularly those of the past 20,000 yr or so, and of the physical factors determining climate. The presentation emphasises the role of solar radiation and discusses processes likely to result in variations of solar energy output. The second part examines the influence climatic factors have had on human activity from prehistoric to more recent times. The increasing susceptibility of the rapidly expanding and technologically developing human population to climatic variability is strongly emphasised; an appreciation of this by governments is illustrated by their involvement in discussions of schemes to control weather in various ways—for example, by hurricane modification, rain enhancement by cloud seeding, and the construction of barriers to modify ocean currents. Illustrations are also drawn, mainly from the US experience in Vietnam, of the use of weather modification as a weapon of war. The severe consequences of adverse weather such as droughts and hailstorms on food production over large parts of the globe are discussed in some detail, and the activities of weather modification groups to alleviate the worst effects of these phenomena are given some prominence. The legal aspects of these activities are also discussed.

The third and final part of the book looks to the future. Taking as its basic proposition that there is a one-in-ten chance that the Earth's climate will cool and become more hostile to and seriously affect human activity over a large part of the globe within the next hundred years, it examines in some detail three possible options (apart from doing nothing) open to us for meeting this situation. The first is to adapt ourselves to the anticipated new conditions (for example, by introducing mandatory birth control to stabilise the world population, accompanied by food, water and energy rationing): the second is to try to modify climate locally—for example, by building a dam across the Straits of Gibraltar; and the third is to try to alter the global climate by, for example, blackening the polar ice caps or damming the Bering Straits. The author, after a brief reference to present international research efforts under the Global Atmospheric Research Program and stressing the urgent need for more research, concludes that the wisest course is a flexible mix of options.

The work is written in a highly sensationalist style which never lets up. The author's insatiable urge to impose his ideas on the reader and saturate him in his verbal imagery frequently leads him to use phrases which are logically absurd and amount to little more than scientific mumbo-jumbo. An example of this occurs in his description of a stationary high pressure area over Greenland as "causing a slight vacuum effect in wind patterns that increased cold winds sweeping down into Europe". Another is his description of tornadoes as "masses of cold air bumping into each other in thunderstorms". Some of his diagrams, too, are inaccurate. One of these shows the intertropical convergence zone as penetrating north of the Himalayas and up into Mongolia during the period 1900–1940!

But there is another aspect of this book which I find highly irritating and irresponsible. This is its almost total disregard and arrogant dismissal of the substantial progress made by the worldwide scientific meteorological community in recent years in getting to grips with the fundamental problems concerning the physical basis of climate. The Global Atmospheric Research Program gets a mention here and there, but this hardly compares with the attention given, for instance, to the work of those who predict that an ice age could be upon us in seven years, or who talk of "punching holes" through the ozone layer with laser beams as a possible means of waging war on an enemy. The US National Academy of Sciences has recently produced a highly professional and valuable report (*Understanding Climatic Change: A Program for Action*) but this is referred to only briefly in an Appendix; and the Academy itself is cursorily dismissed as a "staid group".

All this is a great pity and, I fear, could even be dangerous. Lay individuals reading this book (including politicians, one of whom has contributed a foreword) could easily be misled into thinking that meteorologists know enough about global atmospheric behaviour to make a reasonable guess at what will happen to our climate over the next hundred years; and that we are on the verge of being able to change climate to provide a more favourable environment for mankind. The impression is given that only those meteorologists prepared to indulge in climatic prediction and weather modification have any real concern for applying their science to the benefit of humanity and that the others are just sitting back and taking little effective action.

It is a pity that the author has not directed his obvious talents as a publicist primarily towards drawing the attention of those who read his book to the great economic importance of weather and climatic research and to the need for strong financial support for the activities of those who are, and have been for many years, attempting to fill the large gaps in our scientific knowledge of the atmosphere and oceans, and the factors determining their behaviour, particularly on the longer time scales. Contrary to the impression conveyed by the author, most meteorologists see these as the primary goals of the science at this stage in its development. Until we have made more progress in this direction, reliable climatic prediction and control, the main themes of this book, are but pipe dreams. □

R. P. Pearce is Professor of Meteorology and Head of the Department of Geophysics at the University of Reading, UK.

cloth ISBN 0-85274-327-0 £10.00 net
paper ISBN 0-85274-347-5 £7.50 net

Two textbooks written to meet the current need for a comprehensive and systematic treatment of astronomy, including the physical and mathematical groundwork so often omitted from other textbooks. Both books include many worked examples, problems with answers, and a selection of practical projects. Although primarily intended for under-graduate use, these books will enable serious amateur astronomers to study their subject as a working science. They are published in a large format as both casebound and paperbound editions.

Morphogenetics of Karst Regions
L Jakucs *(Szeged University, Hungary)*
A modern geomorphological treatment of the origin of the distinctive geographical features of karsts (limestone areas). It resolves many contradictions between theory and observation, and offers revolutionary new standpoints in karst morphology. There is no similar book.
284 pp illustrated cloth
ISBN 0-85274-309-2 £17.00 net

Operational Calculus
I Z Shtokalo *(Soviet Academy of Sciences)*
The author outlines the development of operational calculus and presents a general course in the subject, before describing his own work and that of his colleagues.
333 pp cloth
ISBN 0-85274-321-1 £16.00 net

Decomposition of Superpositions of Density Functions and Discrete Distributions
P Medgyessy *(Mathematical Institute, Budapest)*
The first substantial monograph devoted exclusively to density functions and the problem of their mathematical separation or decomposition.
308 pp illustrated cloth
ISBN 0-85274-294-0 £12.00 net

Spectrochemical Analysis of Pure Substances
Kh I Zil'bershtein *(Institute of Silicate Chemistry, Leningrad)*
A translation of a major Russian work devoted to the special refinements of technique needed for the spectrochemical analysis of trace elements in high-purity materials. Revised and updated with the full cooperation of the author.
435 pp illustrated cloth

The Analysis of Organic Materials An International Series of Monographs Number 2

The Determination of Sulphur Containing Groups Volume 3. Analytical Methods for Sulphides and Disulphides

M. R. F. Ashworth

May/June 1977, x + 220pp., £11.00/$21.50 0.12.065003.7

This volume, the third on the determination of sulphur-containing groups, presents the methods which are available to detect, identify, separate and quantitively to determine compounds containing a sulphide or disulphide group. The compounds considered are those in which the -S-S groups are attached to carbon atoms linked otherwise only to hydrogen or to other carbon atoms, which covers thia- and dithia-alkanes, cycloalkanes, and arenes. Of the many heterocyclic structures then theoretically eligible for treatment only the important thiophanes and biotin have been included.

Personality and Psychopathology
A Series of Monographs, Texts and Treatises

The Scientific Analysis of Personality and Motivation

R. B. Cattell and P. Kline

June/July 1977, x + 382pp., £11.50/$22.50 0.12.164250.X

Presented here is a comprehensive reference source to the work of Cattell and other factorists. The basic aims of the book are to explicate the results of the multivariate analysis of personality and to integrate Cattell's work with non-multivariate psychological theory. Topics under discussion include different methods of multivariate theory analysis and their application to the study of personality and motivation; types of personality test; the psychological meaning of the main personality factors discovered among normals, subnormals and children; the application of these findings to education and to clinical and industrial psychology, and finally their relevance to psychological theories.

Computational Mathematics and Applications
Series Editor: J. R. Whiteman

This new series on computational mathematics has been conceived in order to fill the gap which exists between numerical mathematics and theoretical applied mathematics on the one hand and engineering and scientific applications of numerical methods on the other. The numerical theme is central to the series and thus topics suitable for inclusion will range from numerical analysis to the application of numerical methods in engineering.

Volume 1

Finite Element Programming

E. Hinton and D. R. J. Owen

June/July 1977, xiv + 288pp., £11.80/$23.00 0.12.349350.1

Contents

Introduction and theory. Assembly of elements and solution of stiffness equations. Input and output. Element characteristics for plane stress/strain. Element characteristics for plate bending applications. Equivalent nodal representation of loads. Discussion and further developments. Appendices. Index.

Electron Spectroscopy: Theories, Techniques and Applications

Volume 1

edited by C. R. Brundle and A. D. Baker

May/June 1977, xiv + 460pp., £24.00/$46.90 0.12.137801.2

This book reflects the feeling that there is much to be gained by bringing the diverse types and applications of electron spectroscopy together. It is felt that advancement of scientific knowledge most often results from cross-fertilisation of ideas emanating from individuals in areas of endeavour which, although seemingly separate are unified by some common aspect. Volume 1 provides basic information on electron spectroscopy and on the application of photoelectron spectroscopy, both x-ray and ultraviolet, to chemical systems. The volume also includes chapters on calculations of energy levels carried out in relation to electron spectroscopic measurements, and on the applications of coincidence techniques to electron spectroscopy in general.

Economic Microbiology

This new multi-volume series aims to provide a fully authoritative and lasting reference work on all aspects of the economic importance of microbial activity.

Volume 1

Alcoholic Beverages

edited by A. H. Rose

June/July 1977, xiv + 760pp., £25.00/$48.90 0.12.596501.X

Contents

A. H. Rose: History and scientific basis of alcoholic beverage production. *A. M. McLeod:* Beer. *F. W. Beech and J. G. Carr:* Cider and perry. *R. E. Kunkee and R. Goswell:* Table wines. *A. Jarczyk and W. Wzorek:* Fruit and honey wines. *K. Kodama:* Saké. *R. Goswell and R. E. Kunkee:* Fortified wines. *A. C. Simpson:* Gin and vodka. *M. Lehtonen and H. Soumalainen:* Rum. *T. P. Lyons and A. H. Rose:* Whisky.

Biometrical Journal

Journal of Mathematical Methods in Biosciences

Presented here are papers on new theoretical aspects of mathematics and its applications to the biological sciences — whether to biology, medicine, the agricultural science or to forestry. The application of mathematical and statistical methods to new areas of science and the mathematico-cybernetic model construction of biological sciences are also discussed. Original papers, summary reports on the latest developments, proceedings of conferences and book reviews are all featured in this journal. The publication languages are English, German, French and Russian.

Included in the papers to be published in 1977 are:
M. Ten Hoopen: Incidental distortions in a point process. *G. K. Murdoch:* A note on Bailey's analysis of the simple stochastic epidemic. *J. Bock:* Sample size determination for the comparison of the regression coefficient with a constant in the case of simple linear regression model II. *V. Guiard and G. Herrendorfer:* Estimation of the genetic correlation coefficient by half sib analysis if the characters are measured on different offspring. *A. M. Fedotov:* A threshold model for analysis of function of homogeneous cell populations. *K. G. Janardan and D. J. Schaeffer:* A generalisation of Markov-Polya distributions its extensions and applications. *P. P. Mager:* Multidimensional analysis of the effects of organic molecules, metabolic inhibitors and drugs on biochemical responses.

Semimetals and Narrow-Bandgap Semiconductors

D. R. Lovett

April 1977, xiv + 258pp., £8.50/$17.50 0 85086 060 1

Although metals and semiconductors have been extensively treated in introductory texts and research monographs, semimetals and narrow-bandgap semiconductors have received less attention. This book sets out to provide a unified treatment of the subject. It is divided into two sections. The first deals with the preparation, electrical properties, and applications of semimetals and narrow bandgap semiconductors in general terms. It contains a discussion of the various methods of crystal growth and the application of phase diagrams, particularly in the production of mixed-crystal materials. The exposition of the underlying theory concentrates on features peculiar to the group of materials, such as the use of intermediate statistics to describe partially-denegrate electron systems. The second section deals with specific elements and binary and ternary compounds, and includes a large amount of experimental data. There is an emphasis on the chalcogenide compounds, many of which, such as lead-tin telluride and mercury-cadmium telluride, are currently of considerable technological importance.

Pion Advanced Biochemistry Series

Aldehydes in Biological Systems

Their Natural Occurrence and Biological Activities

E. Schauenstein, H. Esterbauer, H. Zollner
Translated by P. H. Gore

April 1977, 205pp., £9.00/$18.50 0 85086 059 8

Aldehydes are very widely distributed in living matter and have a surprisingly broad spectrum of chemical and biological functions, ranging from their occurrence as metabolic intermediates, to their more or less selective interference in energy metabolism and biosynthesis, to highly specific biological effects. In addition a large number of aldehydes occur under abnormal physiological conditions. Many of these aldehydes are highly reactive substances and are potent inhibitors of metabolism and cell growth. Thus aldehydes also play an important role in environmental pollution problems. This book is intended as a reference work and presents for the first time a comprehensive literature on the biological effects of naturally occurring aldehydes. An introductory chapter on their occurrence *in vivo*, reactive sites, and mechanisms of action is followed by detailed descriptions of classes of aldehydes and of specific aldehydes, including their structures, reactions with other cellular constituents, and effects on the metabolism both of natural and of cancerous cells.

New books from Churchill Livingstone . . .

THEORY AND PRACTICE OF HISTOLOGICAL TECHNIQUES

Edited by John D. Bancroft and Alan Stevens
436 pages fully illus plus 8 pages of colour plates £13.00

This comprehensive reference volume covers most of the laboratory techniques used in modern histology and histopathology, from the principles of tissue fixation to scanning electron microscopy. Written by histopathologists and technical staff with a wide range of experience it outlines the ways in which material can be handled to yield the maximum information.

INTRODUCTION TO RESEARCH IN MEDICAL SCIENCES

A. Cuschieri and P. R. Baker
226 pages illustrated £3.95

The book deals with the basic principles involved in the setting up and execution of biomedical research projects right through from the stages of literature review to data analysis and presentation of results.

Throughout the book, emphasis is placed on information of a practical nature. This includes research posts, the organisation of research and the requirements for the use and selection of laboratory animals. The principles of animal experimentation, laboratory techniques, and clinical trials are presented, together with useful practical details.

A guide to further reading is given at the close of each chapter, and includes reference books which the authors have found to be particularly helpful.

THE PRESENTATION OF ORIGINAL WORK IN MEDICINE AND BIOLOGY

Hugh Dudley
112 pages illustrated £2.50

This is a general account of the principles and practice of writing papers and of the presentation of short communications at scientific meetings. It is written with particular emphasis on the organisational and practical aspects of communication. All those involved in research medicine and biology will find this book invaluable, whether as a manual for the beginner or as a source of reference for the experienced.

CLINICAL RADIOBIOLOGY

W. Duncan and A. H. W. Nias
234 pages 112 line illus plus 4 half-tone photographs £9.50

This is the first textbook of radiobiology in which the *clinical* requirements of the subject have been given priority. It is an authoritative account of the important principles of radiobiology relevant to clinical radiation oncology.

The authors have throughout tried to make the book as readable as possible, selecting scientific material carefully to emphasise those aspects of immediate interest to radiotherapists, clinical oncologists, radiographers and clinical radiation physicists.

The authors are a professor of radiotherapy and a consultant medical radiation biologist in two of the leading British cancer treatment centres. They both bring to the work over twenty years of practical experience in the day-to-day problems of radiation oncology, and experience in the investigation of radiotherapy's scientific basis through radiobiology research. The book is thus firmly embedded in the practicalities of clinical radiotherapy.

British weather

H. H. Lamb

The Climate of the British Isles. Edited by T. J. Chandler and S. Gregory. Pp. xviii+390 (Longman; London and New York, 1976.) £5.95.

THIS useful book is likely to win wide acceptance as the fundamental reference work that its title implies. It presents a mine of information within a handy size and will serve many practical needs. Its editors, who are the heads of the Georgraphy Departments of Manchester and Sheffield Universities, planned the book as a successor to E. G. Bilham's classic work which appeared under the same title in 1938: this new version, written with more awareness of climatic change, and incorporating a chapter on that topic, is to provide up-to-date observational data, including much (for example, on pollution) that was not available 40 years ago, and an introduction to modern ideas and analysis techniques (notably the greatly increased use of synoptic climatology). Although 12 of the 15 chapters are by scientists holding university appointments and only three by present or recently retired members of the UK Meteorological Office staff, the Office, together with the Irish Meteorological Service and their official publications, have provided most of the data.

The book is on about the same scale as Bilham's, having 390 pages to his 347 and 110 maps and 80 tables to his 101 and 63. Like all works made up of contributions from different authors, however, the style and standard of the chapters in the new work is somewhat uneven (although as regards most, not badly so). One is not told about the qualifications of the authors, but the research fields preferred by all but two of them can be recognised in their works cited in the 560-item bibliography (a very good list of modern references, although omitting some of C. E. P. Brooks's works, such as his *Climate in Everyday Life* and *British Floods and Droughts*, which are still useful).

It is sad to have to criticise anything in such a useful straightforward job as this compendious book. Yet the text is presented in a thin spider's web of print which is also too large for the spacing of the lines and fades to an indecipherable greying of the page in poor light in which Bilham's older text is still clearly readable. Another unhappy choice is the bold poster-print of page-numbers in the index which has no point in combination with the spidery print of the subjects to be identified. The style in itself is not unattractive but is more appropriate to a mail-order catalogue than to a book that is to be read and re-read carefully over many years. By contrast, the printing of the many maps and tables is mostly good; but it is too small, so that a magnifying glass is needed to check many details. In some cases this, combined with awkward spacing of the figuring (as in Fig. 6.6 on p141), presents a real danger of misreading 1.0 as 10 and 2.5 as 25, and so on. It is odd, too, that so few publishers seem to realise the virtue of giving the key date—the year(s) and/or month or season—of each map of a series boldly on the map rather than in a list in small print in the group caption. There are also a few complaints about language. The Gaelic word Eire, which means the whole island of Ireland, is wrongly used in the title of the Irish Meterorological Service and elsewhere in the book to relate to just the 26 counties of the Republic. Another author prefers to use the five-syllable word "altitudinal" when he means "height" differences. In these changing times the fashion for changing names presents problems to writers who have to refer to the geography. This book boldly uses names of new counties in England and Wales, possibly before it is certain that they will stick.

In writing of the book's many virtues it is hard to know what to stress. This reviewer will probably find most occasion to refer to the data in the chapters on wind, radiation, temperature, precipitation, the climates of coasts and inland water bodies, of soils, slopes and vegetation, and the climates of towns. But nearly every chapter is packed with data, presented in forms likely to be of wide usefulness, and some of the other chapters also (for example, on synoptic climatology) are very good and up-to-date.

A few samples of items that struck one reader as interesting either *per se* or as indicating lines of development of the subject will illustrate the content and flavour of the book. First, a point that indicates *inter alia* where further development is needed: the presentation (pp62–68) in text, map and tables of extreme windspeeds having average recurrence periods of just once in 50 and once in 100 yr, derived by sound statistical theory and adopted by the British Standards Institution for basic design windspeeds for buildings, are based in many cases on only 20–30 yr of record (and, in at least some cases, it may be presumed based on the very unrepresentative decades earlier in this century). The table of average yearly number of days with gale at 19 sample places illustrates not only the real gross geography of gales in these islands but how localities (and other things) may change with time and affect the issue. The second lowest frequency of gales (1.3 days per year) is at Mildenhall, Suffolk, now on the edge of Thetford Forest, an area which was known in the seventeenth century when it was open barren land for its storms of blowing sand that ruined many estates.

It is odd that there is no reference to hail in the index, but in the precipitation chapter we learn (p129) that this is an item which has been insufficiently studied and for which data are sparse. Many readers will be interested in the opportunity to compare the raininess of different places in terms of the average duration of rainfall: within the British Isles (in the 1950s) this ranged from $407\,\mathrm{h\,yr^{-1}}$ at Ipswich (427 in the London area) to 616 at Plymouth, 1,157 at Swansea and up to 1,422 in the Western Highlands of Scotland. Cloud-cover apparently varies much less widely, from an overall average of 6.7 tenths at Aberdeen and 7.0 in London and East Anglia to 7.8 in the west and north of Scotland. Another aspect of the western climates comes out in the temperature chapter, where the extreme south-west, the coasts of Wales and south-west Ireland, so favoured for retirement, are pointed up as the areas where the average winter temperatures are not low enough for the vegetation (and the grass of your lawn!) to cease to grow.

Other interesting features include a map of the summer albedo of England and Wales, and diagrams detailing the radiation falling hour by hour on slopes of various angles facing north, east and south. A map of the frequencies of fog, with the greatest frequencies (up to 60–70%) occurring on the high ground, reminds us how poorly represented are the hills in this country by observing sites since the discontinuation already in 1904 of the pioneer Ben Nevis Observatory. There is much that is interesting also in the chapter on coasts and inland waters, although we learn that most of the study of the climate of the latter so far has been left to the freshwater biologists.

This book is a worthy successor to Bilham's, keeping abreast of the climate itself and our developing knowledge of it and its impacts. Altogether good value at the price. ☐

H. H. Lamb is Director of the Climatic Research Unit at the University of East Anglia, Norwich, UK.

Engineering geology

J. L. Knill

Principles of Engineering Geology. By P. B. Attewell and I. W. Farmer. Pp. xxx + 1045. (Chapman and Hall: London; Halsted/Wiley: New York, 1976.) £25.

ENGINEERING GEOLOGY has been the main growth subject within the industrially-orientated aspects of the Earth sciences during the past two decades. The question remains, however, as to whether the success of engineering geology has been a consequence of the development of a new discipline, or is more fairly a reflection of the vocational opportunities for geologists within the construction industry.

The origins of engineering geology, as it is now defined, lay in the heavy construction industry in the early years of this century when geologists were invited to advise firstly on ground problems encountered during construction, and subsequently to assist in the prediction of difficulties during the earlier phases of investigation and design. At that time soil and rock mechanics did not exist as such and so it was natural in civil engineering for geologists to continue to be employed in the United States for the following decades; it was not until the 1950s that systematic education and growth in employment opportunities began to develop on a world-wide scale.

Soil mechanics was, by then, a well-established branch of engineering science, and subjects such as rock mechanics and hydrogeology were also firmly established. Perhaps it was inevitable that engineering geology has tended to move into a central position within the engineering earth sciences, attempting to link together the interactions between rock, soil and water as engineering materials within the realities of natural geological conditions and engineering problem-solving during investigation, design and construction.

There is, in consequence, a considerable element of choice not only in the balance between the component subject areas but also in the extent to which these subject areas are integrated with one another. On the one hand, it can be argued that the professional engineering geologist is essentially a geologist and his knowledge of the engineering disciplines should be maintained at a level that enables him to be able to communicate effectively in an engineering environment. On the other hand, engineering geology can be viewed as representing a balanced approach towards geotechnical engineering drawing together soil and rock mechanics, hydrogeology and geology into a unified whole to that the engineering geologist adopts the role of an engineer.

The authors of this textbook have been concerned for some years with the organisation of a postgraduate course in engineering geology at Durham University, and the structure of the book reflects both the philosophy of this course, and the associated research activities. The book falls into two broad sections, the earlier part providing an approach towards the study of the engineering properties of engineering soils and rocks, whereas the later part deals with more practical, engineering-orientated topics.

The opening chapter provides a general coverage of minerals and rocks, drawing particular attention to clay minerals and their identification and this is followed by a concise review of soil mechanics. The succeeding chapter is a major treatment of the geotechnical and geological characteristics of clays and clay shales, much of the relevant material having been drawn from unpublished research. The text turns to rock as a material, and the influence of symmetry and preferred orientation of micro- and macrofabrics on the properties of rocks and soils. The progressive approach of the authors towards the development of macroscopic fabric diagrams related to stability/instability fields is of particular interest.

At this point the book seems to change step, turning systematically to site investigation, groundwater, soil and rock slope stability, techniques of ground improvement, and the assessment and control of water resources. Most surprisingly, the application of geology to underground works and foundations, two important facets of the subject, are almost completely ignored.

This textbook is an interesting view of engineering geology, more strongly reflecting the engineering aspects than the geological. The arrangement of the book into two parts with somewhat different themes, is, however, not wholly satisfying nor has there been adequate control of excessive detail which penetrates into the text. For a book in excess of a thousand pages and at a price that will deter many, more careful structuring of the book with regard to the potential market could have yielded a shorter, cheaper and more comprehensive text.

The publishers suggest that the book will be of value for courses in both civil engineering and geology; at this price it can only possibly attract those who have already chosen engineering geology or geotechnical engineering as their career field. It has also been suggested by the publishers that "the book will itself eventually become synonomous with the subject area of engineering geology". Many will debate this prediction but it does not detract from the valuable service that the authors have done in drawing together so much useful material. ☐

J. L. Knill is Professor of Engineering Geology at Imperial College, University of London, UK.

Dating in archaeology

Elizabeth Slater

Dating in Archaeology: A Guide to Scientific Techniques. By S. Fleming. Pp. 272. (Dent: London, 1976.) £8.95.

A DECADE AGO, when the application of scientific dating techniques to archaeological material was gaining momentum, this book would have been a welcome addition to the bookshelves of archaeologists. Non-specialists then needed a general introduction to the available methods, with some indication of their potential and limitation, to illustrate the wealth of information that could be extracted from archaeological material and to assist them in the assessment of the validity of the dates produced.

This book follows a standard format with sections devoted to the main dating methods, giving information on the method, the materials to which it can be applied, its accuracy, associated problems and selected examples of its application. There are eight main chapters, plus a useful introductory chapter on the chronological patterns that were developed before the main impact of scientific dating methods, and a final chapter on scientific techniques applied to art history. The methods which reveal aspects of climatic changes are considered in an appendix and the other appendix contains an outline of the pre-dose thermoluminescence technique.

One of the greatest problems facing archaeologists is the interpretation of the information yielded by scientific dating methods. They are left with dates, plus associated errors, and a bewildering array of methods for the manipulation of the data. This problem is more readily acknowledged in the case of radiocarbon dating but it is inherent in all dating methods. The author gives no guidance in this matter, nor does he mention all possible procedures. He may feel that it would be premature to do so, and, as he says, "So many of the finer details of radiocarbon variations remain unresolved that no strong attempt has yet been made to routinely correct older conventional dates . . .". But he adds: "the reader may be tempted to adopt at least one form of correction factor to produce more absolute ages . . ." (p73). The non-specialist, who has to make a selection and evaluate conclusions, understandably requires assistance, or positive or negative recommendations. In the examples given of the application of the methods, Dr Fleming concentrates on the results, and not the validity of their interpretation.

The selection of examples of applications is wide-ranging, and one of the merits of the book is that it draws on material not readily accessible, but some omissions are rather surprising from an archaeological viewpoint. For example, scientific dating has had a considerable impact on the chronology of prehistoric Europe, but two references to the same paper is scant recognition of the lengthy debate which has produced a book and numerous papers. It may be considered that no conclusions are yet possible or that the topic has already been fully discussed, but readers familiar with the arguments will also be conversant with much work in this book. Also, the chronological framework discussed in chapter 1, and that indirectly derived from it, have been discussed in the light of new dating evidence, and a final summary of the continuing validity of the original patterns would have been helpful.

The topics discussed are continually being developed and modified, and the author has made a conscious effort to keep the bibliography up-to-date. Although it is useful to find descriptions of methods, like acid racemisation, which have so far only achieved limited recognition, from the point of view of archaeologists the changes in the main methods have been evolutionary rather than revolutionary in the few years to elapse since the last synopsis was published.

Despite the comments above, there is much of merit in this book. It contains a wealth of information, it is up-to-date, the methods are described clearly with an adequate amount of detail, and the diagrams are particularly clear. One distinctive feature is that analytical techniques and applications which have chronological implications are rightly included. It can certainly be recommended as the most up-to-date text for non-specialists, and the author is only unfortunate that he has followed a path which a number have trod. Perhaps the definitive book on dating, which Dr Fleming is admirably qualified to produce, is not destined to appear in the immediate future. ☐

Elizabeth Slater is Lecturer in Archaeological Science at the University of Glasgow, UK.

History of the Nile valley

Gudrun Corvinus

Prehistory of the Nile Valley. By F. Wendorf and R. Schild. Pp. xxiv+404. (Academic: New York and London, 1976.) $25; £13.75.

THE INTENTION of this book is to assemble and present all the available data and observations made during three seasons of fieldwork (1967–69) along the Nile in Egypt. The first part of the book covers in considerable detail the geology and stratigraphy of the Final Pleistocene Nile sediments between the Assuan and Fayum Depressions, including comprehensive descriptions of sites and sections. The second part describes and revises the sequence of stratigraphical and chronological events, and attributes the archaeological sites to cultural units.

The book is well illustrated with maps, section drawings, drawings of artefacts and photographs which clarify the rather lengthy descriptions of the sites. Regrettably a few names of the areas discussed are not mentioned in any of the maps.

The title of the book is somewhat misleading in view of the detail concerning the geology and palaeoenvironment; this latter is, nevertheless, of considerable value. The purely archaeological descriptions occupy only a small portion of the book.

The most significant contribution that the book makes is the revision of the sequence of events of the Final Pleistocene and Early Recent periods. The authors have assembled and interpreted a considerable amount of new data, filling gaps in the existing knowledge of the prehistory of the Nile and leading them to revise previous concepts.

The principal amendments concern the two large aggradations of the modern Nile. The Ballana Masmas episode is regarded here as one unit of simultaneous dune formation and Nile silt aggradation. A number of carbon-14 dates place this period between 17,000 and 15,000 BC, two different archaeological complexes having been recognised (the Idfuan and the Fakhurian). Furthermore, the Darau Member of the Kom Ombo area and the late Sahaba Formation of Sudanese Nubia belong, according to the authors, to the same episode of Nile aggradation and are termed here the Sahaba–Darau aggradation. The archaeological sites attributed to this period, dated from 12,000 to 9,700 BC, are the Afian, the Sebilian and the Isnan industries.

The authors are to be commended in attempting to compile and interpret such a vast amount of data. The book will serve as an excellent base for further research and as a reference for comparative studies, and will mainly interest the specialist in this field. ☐

Gudrun Corvinus is a consulting archaeologist to the Consolidated Diamond Mines of South-west Africa, Oranjemund.

Lake Rudolf Basin

G. E. Kennedy

Earliest Man and Environments in the Lake Rudolf Basin: Stratigraphy, Paleoecology and Evolution. Edited by Y. Coppens, F. Howell, I. Clark, L. Glynn and R. E. F. Leakey. Pp.xxi+615. (University of Chicago: Chicago and London, 1976.) Cloth £11.90; paper £5.80.

PALAEOANTHROPOLOGISTS have often discussed the value of an interdisciplinary, 'synthetic' methodology and yet this approach has not been highly visible in the literature. This book, and the recently published *After the Australopithecines* (ed. K. W. Butzer and G. L. Isaac; Mouton: The Hague and Paris; Aldine: Chicago; for review, *see Nature*, **262,** 331, 1976) may represent a strong sign that broad interdisciplinary analyses of early man sites will become the rule rather than a rarity. It is no doubt a sign of this trend that reports of the hominids found at East Rudolf comprise only five papers out of a total of fifty in this volume. These papers, presented at a workshop held in Nairobi in September, 1973, have been arranged into three sections: Geology and Geochronology; Paleontology and Paleoecology; and Paleoanthropology.

From this volume it is apparent that there are areas of both agreement and disagreement among the thirty-eight scientists who were involved in the Nairobi workshop. An interesting area of agreement concerns the occurrence of a climatic change between 2.5 and 2.0 Myr BP. This change, which resulted in drier conditions and an expansion of grassland areas in the Rudolf basin, has been indicated by studies on pollen (Bonnefille), bovids (Gentry) and micromammals (Jaeger and Wesselman). Documentation of climatic change at this time is of particular interest because the first clear evidence of archaeological materials also occurs within this period. Although the relationship, if any, between climatic change and the appearance of cultural materials is unclear, this interesting association requires more investigation.

From the standpoint of early man studies, one of the major outstanding questions is the date of the KBS tuff. The date of this tuff is crucial because there is good evidence of the presence of the genus *Homo* below this level. The results of radiometric studies have been contradictory, ranging from 1.6 to 2.6 Myr BP for this tuff. As Cooke's paper indicates, the earlier date for the KBS tuff may be suspect on palaeontological grounds. Cooke's studies on fossil pigs has shown that tooth size in one taxon, *Mesochoerus limnetes*, found below the KBS tuff at East Rudolf most closely resembles that in specimens from the nearby Omo area dated to 2 Myr BP.

This important volume contains a wealth of detailed and important information, and will be very useful at the professional level. Its information, however, will be less accessible to students. Although each of the three major sections is prefaced with an introduction, these are far too brief to really open the major issues and questions posed by each area of research. Such interdisciplinary studies are most valuable when they result in a synthesised and comprehensive view. Although such synthesis is missing here it is a minor defect in an otherwise fine volume. ☐

G. E. Kennedy is Assistant Professor in the Department of Anthropology at the University of California, Los Angeles, California.

Hominid and the bathwater

W. W. Bishop

Geology of the Olduvai Gorge: A Study of Sedimentation in a Semiarid Basin. By R. L. Hay. Pp. xvi + 203. (University of California: Berkeley, Los Angeles and London, 1976.) £15.75.

RECENT interest in Earth science has promoted fruitful growth of such 'interface' studies as geochemistry, geophysics, and geobiology. It comes as no surprise to see the common ground between geology and archaeology also attracting attention. What is unusual is to find, within the 200 pages of a single-author volume, a blue-print for the application of various disciplines to the study of sediments yielding hominids and artefacts. These include stratigraphy, geochronology, sedimentary petrography, mineralogy, isotope geochemistry and amino acid chemistry, to mention but a few.

On this substratum Dr Hay builds a sophisticated time framework for the past 2 Myr and reconstructs palaeoenvironmental settings for the hominids, their artefacts and, by inference, their activities in the changing palaeogeography of the Olduvai region.

Olduvai was the area where large scale excavations by Louis and Mary Leakey showed geologists, vertebrate palaeontologists and even some archaeologists, how local microstratigraphy could be studied to set early hominids and their palaeolithic took kits against a factual background from which to decipher the environment of burial and, with luck, the habitat of life. Dr Hay, with early experience of the stratigraphical complexity posed by arid intermontane basins in western USA, was the ideal successor to other geologists (Hans Reck, E. J. Wayland, P. J. H. Boswell, P. E. Kent and R. A. Pickering) who worked at Olduvai. It was fortunate that he appeared on the scene in 1962 after initial over-concern with alleged pluvial–interpluvial 'climatic stratigraphy' had been passed over in favour of a return to 'normal' stratigraphical and geological methods.

The finding of the skull of *Australopithecus* (*Zinjanthropus*) *boisei* in 1959 was the trigger mechanism for new investigations. Olduvai witnessed the first application of K–Ar dating to rocks as young as 1 or 2 Myr. Dr Hay tabulates the 57 K–Ar ages established for Bed I since the initial investigation by Curtis and Evernden, and discusses them in relation to fission-track dating and palaeomagnetic polarity data. Beds II to IV yield few reliable K–Ar dates, but numerous radiocarbon ages are given spanning the past 30,000 yr at Olduvai.

For the archaeologist the most important sections of the book are those presenting palaeogeographic reconstructions, both descriptive and visual (18 out of 27 maps in a total of 63 text figures), based upon detailed stratigraphical columns, which are also excellently illustrated by pull-out sections. These provide the factual and the interpretative environmental record against which Dr Hay records the hominid and artefact content of each formation. The final chapters present a synthesis in the form of a four-page evolutionary history of the Olduvai basin and a discussion which in 7 pages distils evidence for the pattern of hominid activities.

Despite its high price this is a book to purchase as well as to read, for its seems certain to become a 'classic'. It demonstrates how geochronology and the study of palaeoenvironments may be used to obtain full value out of both the fossil baby and the sedimentary bathwater.

W. W. Bishop was Professor of Geology at Queen Mary College, University of London, UK. He died on 19 February this year at the age of 46.

THE BULLETIN OF THE BRITISH MUSEUM (NATURAL HISTORY)

Unlike the usual research journal the Bulletins of the British Museum (Natural History) appear at irregular intervals and each is a comprehensive monograph on a specific subject.

Development of bioenergetics

A. R. Crofts

A New Look at Mechanisms in Bioenergetics. By E. Racker. Pp. xiv+197. (Academic: New York, San Francisco and London, 1976.) $9.50; £5.80.

PROFESSOR RACKER has ranged widely in his experience of research in bioenergetics, and this small book chronicles his activities in the field over the past ten years or so. The book takes the form of, and is based on, a series of lectures to students; it is aimed at the undergraduate or early postgraduate level rather than at established research workers. The chapters are prefaced by some admirably chosen quotations, and the text is interspersed with homilies and cautionary tales. The subject matter covered includes substrate level and electron transport-linked phosphorylation, ATP-driven ion pumps, resolution and reconstitution of the different complexes of enzymes which catalyse these activities, and details of the enzymology of these complexes.

Racker has played a major role in catalysing an acceptance of the chemiosmotic view of the mechanism of catalysing an acceptance of the chemiosmotic view of the mechanism of coupling between electron transport and phosphorylation. The book describes fully the very nice work carried out by Kagawa, Hinkle, Kandrach, Ragan and many other colleagues in collaboration with Racker, on the reconstitution of oxidative phosphorylation in liposome vesicles, using the purified enzyme complexes of the mitochondrial apparatus. This work had a strong biochemical appeal, which won over many of those in the field (and there were many) who had blanched at the large body of biophysical evidence previously available, that supported a similar view. The demonstrations that the mitochondrial ATPase, cytochrome oxidase and NADH$_2$ dehydrogenase could separately act as proton pumps when incorporated into liposome vesicles, and that when the ATPase was incorporated together with any of the electron transport complexes, the electron transport could drive phosphorylation, provided a powerful support for the argument for a chemiosmotic mechanism.

Most dramatic of all, however, was the demonstration, in work with Stoeckenius, that the purple membrane protein of Halobacter could be similarly reconstituted as a light-driven proton pump, and that inclusion of the ATPase in the vesicles led to a preparation capable of photophosphorylation. In this case, a clear distinction was evident between the requirement for a device for pumping protons, and an electron transport system. The former was necessary, but not the latter, so that the obligatory coupling between electron transport and phosphorylation predicted by chemical and conformational hypotheses for the mechanism of coupling could be excluded. It is perhaps a minor criticism of this book that the controversy over the mechanism of coupling is framed in such a way as to highlight these biochemical contributions. This is only human; the book cannot be recommended as a completely balanced view of the development of the subject, but, rather, as a personal view.

The other criticism I have to make relates to the "lessons" which crop up here and there, especially at the beginning of the book. These are asides, included perhaps to entertain the reader, and for the most part they are sensible and amusing. Some of them, however, strike me as ham-fisted. For example, Racker is being both cynical and unjust when he teaches with reference to Mitchell's preliminary paper on chemiosmotic coupling: "If you propose a brilliant, new hypothesis and avoid being specific, you probably will be ignored. If you want attention be sure to include a few features that are not essential for the main theme, but open to attack". Several other of the lessons also read like tips to a trainee con-man rather than distillations of wit and wisdom. The quotation above reflects more Racker's own late conversion to Mitchell's point of view than the considerable impact of this early paper; Racker (to his credit) draws attention to this tardiness of his in the preface.

These criticisms are, however, trivial, and I would not wish to discourage anyone from reading this book. It provides a lively and fresh insight into the subject, avoids obscurity and mystification, and provides a more than usually straightforward account of the development of an area of research, mistakes and all, in one of the most influential laboratories in the field. □

A. R. Crofts is Reader in the Department of Biochemistry at the University of Bristol, UK.

Molecules in solution

J. M. Creeth

Biological Macromolecules and Polyelectrolytes in Solution. By Henryk Eisenberg. Pp. xviii+269. (Clarendon: Oxford; Oxford University: London, 1976.) £16.

FEW developments in physical biochemistry over the past two decades have had greater impact than that initiated by Casassa and Eisenberg in the years 1960–64. In a notable series of papers, a theory was described which dramatically simplified the measurement of molecular weight in ternary systems. This was most timely: it coincided with a surge of interest in charged polymers and with the recognition of the subunit structure of many proteins, where measurements were often necessarily made in high concentrations of urea, etc. Such systems were now shown to be amenable to analysis by pseudo-ideal equations, with the twin provisos that the solutions were at dialysis equilibrium and, most characteristically, that the multiplying coefficients (for example, a specific density increment) were defined at constant chemical potentials of the permeating components. In this way, all the effects of interaction (no matter how great) disappeared with the introduction of the appropriate coefficient.

The theory was very soon accepted, but, by the majority, perhaps, more on trust than by conviction, for the mathematics were undeniably tedious. The appearance of a volume by Professor Eisenberg devoted to a comprehensive account of macromolecules in solution is therefore an important occasion. The author has taken full advantage of the opportunities presented to him: a useful summary of the chief structural features of proteins and nucleic acids is followed directly by chapters on the fundamental thermodynamics of ternary solutions. Here the Casassa–Eisenberg concept is developed from first principles: this section contains a clear exposition of the meaning of the preferential interaction parameter, which should be read carefully by anyone tempted to refer loosely to 'solvation' or 'salt-binding'. The notation has been considerably simplified, and accordingly the essential concepts can now be grasped much more readily.

In the chapter devoted to partial volumes, density and refraction increments, the significance of the restriction of constant chemical potential is fully explained: a simple sketch brings home forcibly the meaning of each step. Here also we find the essential conclusions concerning the magnitude of the interaction coefficients: the practical demonstration that these do not vanish in the limit of zero concentration is, of course, the justification of the method. Most readers, I think, would now agree that the conventional 'buoyancy factor' in the equations of sedimentation should be replaced by the density increment, although some would, perhaps, regret the loss of the conceptual aid provided by **v**, with its reminder that the experiment determines the molar volume.

The remainder of the book is devoted to the four chief experimental procedures—light scattering, sedimentation equilibrium, sedimentation velocity/diffusion, and viscosity—each being treated in terms of the new definitions when appropriate. In addition to conventional methods, the newer technique of intensity-fluctuation spectroscopy is described, and the chapter on sedimentation equilibrium includes a section on density gradients which is notable for its vindication of the original theory of Vinograd and colleagues for the distribution of charged macrospecies. Those wishing to find their way through the tortuous paths of associating systems will find the rather sweeping assumptions made in this field clearly set out and assessed, and a useful summary is given of the procedures devised by Yphantis and Roark for the elimination of the effects of non-ideality.

The equations of transport are distinctly more complex than those relating to equilibrium, but this section will interest many for its revision of the theory of Alexandrowicz and Daniel, and the subsequent proof that the limiting sedimentation coefficient of a charged polymer may also be described in terms of the macromolecular component alone, when this is formulated in terms of the theory.

The volume is completed by a series of appendices devoted to thermodynamic concepts (including irreversible process theory) and the references, which are conveniently divided into categories of broad interest and of specific detail. The general standard of presentation is excellent, the few printer's errors noticed being essentially trivial—no mean feat in view of the complexity of notation.

The book will undoubtedly please the theoretician, for the logic and elegance of the mathematics; however, I think that most of all, it will be a delight to the concerned experimentalist, who will find the essential practical procedures and necessary precautions summarised concisely, in readily accessible form, together with the underlying theory. No laboratory working with macromolecules in solution should be without its copy. ☐

J. M. Creeth is Research Fellow in the Department of Biochemistry, University of Bristol Medical School, Bristol, UK.

Darwinism at a cellular level

Leslie Brent

Immunology, Aging and Cancer: Medical Aspects of Mutation and Selection. By F. M. Burnet. Pp. 162. (Freeman: San Francisco, 1976.) Hardcover $9.95; softcover $6.50.

THIS slender volume is based on lectures given by Sir Macfarlane Burnet in 1975 to students at the University of California, Irvine, and at Southampton University Medical School. It is an audacious and successful attempt to scan the wider horizons of immunobiology and genetics by examining and linking such fundamental issues as immunological homeostasis, the ability of cells to repair errors created in their DNA during the mutagenic process, the problem of aging, the pathogenesis of certain genetic and autoimmune diseases, and cancer.

According to Burnet, the common thread of the book is Darwinism at a cellular level. Although other theories have been put forward, it is somatic mutation that is most likely to account for the great diversity of antibodies and the cells that produce or carry them, and it is somatic mutation—coupled with a diminishing effectiveness of DNA polymerases and other enzymes in aging organisms to repair DNA errors—that leads to the manifestations of old age. Likewise, it is the accumulation of DNA errors in lymphoid cells that results in autoimmune disease, whereas the same phenomenon in somatic cells in general leads to the formation of malignant clones that, clinically, we call cancer.

Burnet is as adventurous and vigorous as ever in his discussion of these problems. Although it is true that many of his ideas have been developed at greater length in his earlier writings, this does not in the least detract from the value of this book; on the contrary, it is immensely readable precisely because of the economy of argument. The combination of brevity and global approach nevertheless imposes its own limitations, examples and data are selected fastidiously and, despite occasional warnings that the author's notions may eventually be shown to be wrong, the reader is sometimes left in the dark about points that might have been regarded as detrimental to them. For example, the superficially attractive idea that mast cells are fully differentiated T lymphocytes, bearing roughly the same relationship to each other as plasma cells do to B lymphocytes, is itself based on a questionable premise—that the immunoglobulin receptors of T cells are secondarily acquired from B cells shedding superfluous monomeric IgM. The existence of immunoglobulin-like T-cell receptors, let alone their origin, is still disputed. If it is true that T cells do not possess home-made receptors and that B-cell receptors are created by somatic mutation, it is reasonable to ask how it is that T cells have eluded this basic genetic mechanism and why it is that these cytophilic receptors are so difficult to demonstrate on T cells.

In the chapters on mutation and aging, Burnet explains that both bacteria and mammalian fibroblasts can make good errors in their DNA caused by *in vitro* exposure to ionising radiation. He proposes that the differences in the average lifespans of mammalian species can be largely, if not wholly, explained by differences in the efficiency of the DNA repair mechanism. Apart from the fact that this hypothesis disregards other possible factors, such as the more severe metabolic requirements imposed on small mammals by their high surface/volume ratio, even experts in this field are not yet certain of the extent to which DNA repair influences lifespan. In the words of R. E. Hart (in *Aging Carcinogenesis, and Radiation Biology*, ed. K. C. Smith, Plenum: New York, 1976.): "Indeed, at this time it would be premature to infer that DNA repair in and of itself is a primary determinant of lifespan, much less to state that a single repair process is of more significance than any other". Be that as it may, Burnet does not envisage that immunological processes play a primary part in aging but, rather, that they are brought into play as a result of accumulated errors in aging somatic cells, thus producing autoimmune diseases; and that aging of the lymphoid cells themselves leads to decreased efficiency in immune surveillance, thus permitting the development of malignant clones. Little credence is given to the suggestion that viruses may be playing a critical role in some so-called autoimmune diseases, and in re-stating the hypothesis of immune surveillance there is no mention of the experimental evidence that has, in recent years, somewhat weakened this highly attractive idea—certainly so far as T-cell surveillance is concerned. I am thinking here mainly of the observations that neither "nude" (T-cell deficient) mice, nor mice treated from birth with antilymphocyte serum, show a markedly increased incidence of various kinds

New Chemistry Titles

Chemical Carcinogens

edited by **Charles E. Searle,** *University of Birmingham*
ACS Monograph Series No. 173

Contains comprehensive accounts of the latest theories of cancer chemistry and biology and of the major hazards identified so far. A valuable resource for scientists engaged in cancer research and occupational health studies, this monograph covers material on carcinogen testing methods, co-carcinogenesis and endocrine aspects of cancer, and various classes of carcinogens in polluted air and tobacco smoke, in plants and foods, in many chemicals used in industry and laboratories, and in soots, tars, and oils. (Over 3500 literature citations.)

". . . an admirable and much needed attempt to present the available facts and some of the theories . . . invaluable to research workers and administrators concerned with cancer problems. . . . The preface . . . is an excellent review of the present position of the subject. . . . There are 16 chapters written by 23 experts in their fields. . . . The book is well produced, easy to handle . . . and provides an excellent overview and reference work. . . ."
Nature (1977) **Feb.** (265)

". . . a tremendously useful review of the state of knowledge for those in the field, or for those who must make judgements concerning exposure to chemical compounds . . . . (an) enormous amount of information . . . compressed into a single volume."
Atmospheric Environment (1977) **May**

788 pages. Cloth. (1976) $67.50/£45.00
LC 76-26515 ISBN 0-8412-0226-5

Chemical Mechanisms in Bioenergetics

edited by **D. Rao Sanadi,** *Boston Biomedical Research Institute*
ACS Monograph Series No. 172

The six chapters in this volume discuss the fundamental aspects of bioenergetics with emphasis on the underlying chemical mechanism. Major topics covered in depth include biothermodynamics, biomembranes — structure and function, membrane transport, chemical reactions in oxidative phosphorylation, mechanisms in photosynthesis, and the mechanism of muscle contraction.

". . . a valuable source for specialists and graduate students and is suggested as a reference for libraries."
Electrochemical Progress (1976) **Nov.,** 13

272 pages. Cloth. (1976) $28.50/£19.00
LC 76-26707 ISBN 0-8412-0274-5

Molecular Sieves—II

edited by **James R. Katzer,** *University of Delaware*
ACS Symposium Series No. 40

Fifty-eight program papers from the Fourth International Conference on Molecular Sieves. Review papers as well as those describing original research results cover five main areas: structure, synthesis and modification, adsorption and diffusion, catalysis, and technological applications. These chapters illustrate the shift in research emphasis from classical framework structural papers to those concerned with the location and properties of transition metal complexes in zeolites.

732 pages. Cloth. (1977) $30.00/£23.00
LC 77-720 ISBN 0-8412-0362-8

Radiation Effects on Solid Surfaces

edited by **Manfred Kaminsky,** *Argonne National Laboratory*
Advances in Chemistry Series No. 158

The twenty papers in this symposium feature current research results in three significant areas: basic surface processes occurring under surface irradiations with atoms, ions, neutrons, electrons, positrons and photons (including x-rays); recently developed techniques based on particle and/or photon irradiations of surfaces; and surface irradiation effects in solar and nuclear energy applications.

397 pages. Cloth. (1976) $32.50/£25.00
LC 76-51209 ISBN 0-8412-0331-8

Organotin Compounds: New Chemistry and Applications

edited by **Jerold J. Zuckerman,** *University of Oklahoma*
Advances in Chemistry Series No. 157

Nineteen chapters discuss recent chemistry and commercial applications including homolytic reactions; organostannylanionoin chemistry; organotins as catalysts; organotin alkoxides and amines; use of estertin stabilizers in PVC; organotins as agricultural fungicides and miticides, as industrial biocides, and as surface disinfectants; mitochondrial functions; bioorganotin chemistry; spectroscopy; optical stability; and triorganotin compounds.

299 pages. Cloth. (1976) $32.50/£25.00
LC 76-54338 ISBN 0-8412-0343-1

High-Level Radioactive Waste Management

edited by **Milton H. Campbell,** *Exxon Nuclear Co., Inc.*
Advances in Chemistry Series No. 153

Twelve papers identify technical centers and technical experts working toward improved immobilization and storage techniques. Specific topics concentrate on the U.S. federal government's philosophy and policy; waste management at government sites where the waste is generated; commercial reprocessing plants; efforts at long-term solutions; and waste management practices in Europe.

"Having an adequate index and bibliography, excellent illustrations and good stylistic properties, the work is highly recommended as a reference volume for libraries."
Choice (1977) **April**

166 pages. Cloth. (1976) $18.50/£14.25
LC 76-25020 ISBN 0-8412-0270-2

Electrochemical Studies of Biological Systems

edited by **Donald T. Sawyer,** *University of California*
ACS Symposium Series No. 38

The major emphasis of these twelve chapters is on the study of the redox properties of model compounds for biological systems. Specific topics include vitamin B_{12}, cytochrome c, ligand structural modifications, metalloporphyrins, N-bridged dimers, reduction of nitrogenase substrates, redox model for mitochondrial superoxide dismutase, interfacial behavior of purines, mediator-titrants, rotating ring disk enzyme electrode, model for a mammalian heart, and analysis of NTA and EDTA in water samples.

216 pages. Cloth. (1977) $15.50/£15.00

of tumours. That immunosuppressed kidney allograft recipients have a greatly increased incidence of lymphoid tumours provides far from convincing evidence for the hypothesis, as the immunosuppressive drugs used could themselves be carcinogenic for lymphocytes or, alternatively, chronic stimulation by alloantigens might act as a trigger for malignancy in lymphoid tissues.

We must be grateful to Sir Macfarlane for giving us a highly readable and stimulating book, although the general reader should be warned that some background knowledge of immunology or genetics is desirable if he is to get the most out of it. ☐

RNA polymerase

Walter F. Mangel

RNA Polymerase. Edited by R. Losick and M. Chamberlin. Pp. ix+899. (Cold Spring Harbor Laboratory: Cold Spring Harbor, New York, 1976.) $38.

GENE EXPRESSION and its control has, for the past 30 years, been one of the more fruitful areas of research for molecular biologists. The intriguing results of the bacterial geneticists enticed many biochemists and physicists to seek molecular explanations for such widely diverse phenomena as the inducible metabolism of sugars, the initiation of DNA synthesis and the temporal expression of bacteriophage genes. In most cases, they ended up studying transcription. This book summarises their progress and illustrates the multifarious and subtle ways that have evolved to control gene expression at the level of RNA polymerase activity. Now they are studying the primary sequence of *lac* operator DNA, the RNA primers for DNA replication and the phage-induced RNA polymerases.

Losick and Chamberlain are to be congratulated for having designed an excellent book which will be useful to those who desire a comprehensive introduction to the subject, as well as to those who are actively carrying out research in the field. It is also an excellent text for graduate students. The first half of the book contains an historical introduction by Weiss, an overview of the transcription process by Chamberlin, and eleven review articles that outline the active areas of research. The second half consists of 32 previously unpublished research articles. As with all Cold Spring Harbor monographs, this one contains an extensive and useful list of references.

In his introduction, Weiss describes how the discoveries of different but specific tRNAs and of nucleoside triphosphates as substrates for DNA synthesis led him to assay for an RNA polymerase activity in a crude rat liver homogenate. And in the next article, Chamberlin summarises the work done in the intervening 17 years. His overview of both the molecular and catalytic properties of RNA polymerase is comprehensive, integrating properties of the *Escherichia coli* enzyme with those from other prokaryotic and eukaryotic cells. This is followed by a highly practical article by Burgess on the purification and physical properties of the enzyme. Zillig, Palm and Heil discuss the functions and re-assembly of the subunits, and Krakow, Rhodes and Jovin describe the use of inhibitors to study catalytic mechanisms. The intriguing problems of how RNA polymerase recognises a promoter, initiates transcription and terminates RNA synthesis at specific sites, are discussed in articles by Chamberlin, Gilbert and Roberts. Scaife delineates the progress in the location of the genes for RNA polymerase and the control of their expression. Transcription patterns in bacteriophage infections are controlled, in some cases, by regulatory subunits or bacteriophage-induced RNA polymerases, as outlined by Losick and Bautz. Roeder discusses the properties of nuclear RNA polymerases and some of the problems encountered in studying eukaryotic transcription. Finally, Kornberg defines the role of RNA primers in DNA replication.

The research articles in the second half of the book are specific extensions of each of the areas described in the first half. There are three articles on promoter sequences. With nine promoters having been sequenced, common features, such as twofold axes of symmetry, are emerging. RNA polymerase will not, however, rebind to promoter fragments isolated by protection from DNase, so that additional elements remain to be discovered. The inhibitor, rifampicin, has been extremely useful in studying RNA chain initiation, and there are three articles which indicate that the mode of action of the drug is surprisingly complex. Rifampicin-resistant mutants made possible the mapping of the β subunit. In four articles, the locations of the other subunits are described and shown to be linked with the genes of some of the proteins of the translation apparatus. There are four papers on the regulatory subunits which become associated with RNA polymerase after bacteriophage infection. With the discovery that the rho gene maps at the suA locus, the termination step in RNA synthesis is a very active area of study and is represented by six papers.

Finally, there are some excellent articles on eukaryotic RNA polymerases from yeast, *Drosophila* and mammalian cells. Although the activity of RNA polymerase is modulated to control gene expression in prokaryotes, similar mechanisms have not yet been observed in eukaryotic cells. An elephant may still be a big *E. coli* but it is, ironically, less obvious when viewed at the level of transcription.

This is an excellent book on an important and fascinating subject. ☐

Genetic evolution

Thomas H. Jukes

Molecular Evolution. Edited by Francisco J. Ayala. Pp. x+277. (Sinauer Associates: Sunderland, Massachusetts; Freeman: Reading, 1976.) Paperback £6.90.

THIS book is a compilation of thirteen papers that were presented at a symposium held at the University of California, Davis, in June, 1975. Most of the articles are more closely related to population genetics than to molecular evolution.

There is an introductory chapter by Francisco J. Ayala followed by chapters on genetic variation in natural populations (Robert K. Selander); genetic polymorphism and enzyme function (George B. Johnson); allozyme variation: its determinants in space and time (Michael Soulé); genetic strategies of adaptation (James W. Valentine); organismic and molecular aspects of species formation (Theodosius Dobzhansky); genetic differentiation during speciation (John C. Avise); biochemical consequences of speciation in plants (Leslie D. Gottlieb); protein sequences in phylogeny (Morris Goodman); molecular evolutionary clocks (Walter M. Fitch); evolution of genome size (Ralph Hinegardner); evolution of repetitive and non-repetitive DNA (Glenn A. Galau, M. E. Chamberlin, B. R. Hough, R. J. Britten and E. H. Davidson); and gene regulation in evolution (Allan C. Wilson).

The discussions of molecular matters occur principally in the final five chapters. Goodman's observations lead to his concluding that the evolution of globin sequences in vertebrates proceeds at different rates during different evolutionary periods. He attributes the "fast evolution to positive natural selection for improvements in the function of hemoglobin and the slow evolution to stabilising natural selection after the improvements were fixed", following which "natural selection would then be able to shape the finer adaptations of the protein". It is possible to propose, however, various interpretations to account for such observations, and Goodman acknowledges this point.

Fitch, in discussing molecular evolutionary clocks, says that "we have several sloppy clocks", which may be an example of sloppy diction. He states that "the tRNAs are mostly paralogous", which was news to me, because there are many examples of homologous tRNAs for the same amino acid occurring in related species of organisms. Obviously, many thousands of such tRNAs have not yet been sequenced. Fitch tells us it came as something of a shock to him that Δ haemoglobin has never been sequenced, which leads me to comment that those who accept the sequences in the *Atlas of Protein Sequence and Structure*, instead of referring to the original literature from which the sequences are derived (sometimes by presuming the sequences of unordered peptides), should expect such shocks. Fitch gives a good discussion of the rates of 'silent' nucleotide substitutions. He challenges comparisons of snake, bird and turtle cytochromes *c* by suggesting that "either one or more of its sequences is incorrect", which is an easy out of the argument.

The review by Galau and co-workers is a valuable compilation of recent results on the rate of re-association of various types of DNA. Wilson presents an excellent summary of the differences in rates of evolution between frogs and placental mammals in support of his thesis that contrasts the rates of organismal change and structural gene evolution. The apparent similarities of different species of frogs to each other conceals the fact that they may be widely separated in terms of ancestral history, and also in terms of amino acid differences between their homologous proteins. Hinegardner discusses the wide variations in haploid DNA contents per cell in various groups of organisms. The DNA content per cell has increased during the history of life on Earth, but mammals do not lead the parade.

I wish that the term "nonsense" for polypeptide chain-terminating codons, and the non-word "missense" for mutations that produce single amino acid changes (as used and defined by Ayala) could be relegated to the graveyard of discarded and superseded neologisms. But new words never seem to die, or even fade away. ☐

Somatic cell hybrids

R. T. Johnson

Cell Hybrids. By N. R. Ringertz and R. E. Savage. Pp. 366. (Academic: New York and London, 1976). $29.50; £20.95.

THERE are relatively few events in the recent history of biology which have so fired and re-directed the imagination as somatic cell fusion. Suddenly, in the mid-1960s, the unexpected and unnatural seemed commonplace in cell biology. Somatic cells of diverse origin and nature could be brought together within a single cell, their interactions studied and their hybrid progeny cultured for subsequent analysis. The revolution that Sendai virus-promoted fusion brought to the embryonic subject of cell hybridisation not only permitted the achievement of a greater number of fusion events by a greater number of people but also generated the enthusiasm to develop hybrids between seemingly impossible combinations of cells. The search for agents that promote fusion between unlikely partners remains an area of continuing interest, with the recent demonstration of polyethylene glycol-induced fusion of human and plant cells.

The unusual attraction and usefulness of cell hybrids to biologists soon became evident from the growing number of publications covering a very wide area of contemporary biology. Cell fusion rapidly became one of the most attractive ways of detecting differences between cells. By combining two cells it is possible to monitor some of their differences by following interplay with respect to such general genetic activities as the initiation of RNA and DNA synthesis, and more specifically, to the extinction, re-expression and activation of single genes. Although fraught with difficulties, the analysis of the differentiated state by means of cell hybrids has now progressed to a stage where general rules for the expression of facultative functions can be expected before long. Similarly, the usefulness of somatic cell hybrids in gene complementation and mapping is in no doubt, and advances here and in the study of differentiated expression in hybrid cells are fortunate to have coincided with a revolution in methods for chromosome identification. Cell fusion has also provided an opportunity to study the nucleocytoplasmic interactions in mammalian cells in ways which are similar to the investigations so elegantly carried out using the technique of nuclear transplantation in large cells like Protozoa or amphibian oocytes.

In this well illustrated volume the authors have gathered together, for the first time, the accumulated work up to the end of 1975 on somatic cell fusion and cell hybrids. This is a large, complex, controversial and expanding field and we are therefore indebted to Drs Ringertz and Savage for this timely compilation and review of the subject, reduced to manageable proportions and written with clarity.

The aim of *Cell Hybrids* is to provide an up-to-date account of the contributions made by cell fusion and cell hybrid studies to major areas of somatic cell investigation including cell cycle control, the expression of differentiated functions and malignancy, and the mapping of constitutive genes. It is also intended that the volume should serve as an introduction to students and to workers in other areas. A useful background is therefore included in each chapter providing sufficient information for critical appraisal of results obtained.

Because of their limited lifespan animal cell heterokaryons are less frequently investigated than their hybrid progeny. As the authors stress, however, heterokaryons permit analysis of regulatory phenomena in the presence of complete genomes and should be included whenever possible in any full description of gene expression in hybrid cells which usually contain a reduced and occasionally modified complement of chromosomes. Possibly the most famous heterokaryons contain chick erythrocyte nuclei which, as Henry Harris showed 12 years ago, are reactivated from the quiescent state. Much of the elegant work on erythrocyte activation has emerged from the Karolinska Institute and this is well represented in *Cell Hybrids*.

The very great problems that attend the unravelling of genetic interplay in somatic cell hybrids may to some extent be reduced by the use of reconstructed cells, and a full description of this new area of cell manipulation is included. For example, the production of hybrids by the fusion of whole cells with microcells containing very small quantities of DNA not only predetermines the segregation pattern but may speed up and ultimately simplify the analysis of gene localisation and regulation.

The advent of cell hybridisation has permitted many new experimental approaches to major and seemingly intractable biological problems. A number of the problems have now been reduced in stature and others re-defined because of cell hybrids. We should be grateful to the authors for this comprehensive and readable work on the subject.

Quantitative cell information quickly and accurately:

THE BARR & STROUD GN5 Integrating Microdensitometer

Improved image analysis techniques give fast scans of only 4 seconds duration with 0.25 micron resolution in the GN5 Integrating Microdensitometer. For accurate histochemical and cytochemical studies of your cell preparations this new instrument offers an accuracy better than ± 1% over an optical density range from less than 0.1 to greater than 2.5. Area measurement, electronic masking and narrowband illumination are some of the features which make this instrument particularly suited to your laboratory. The Barr & Stroud GN5 gives quantitative cell information fast and accurately. It is compact, reliable and ergonomically designed for easy operation.

Cell Membrane Iodination
Iodosulfanilic Acid [^{125}I] Labeling Kit

High specific activity agent labels only cell membrane surface proteins. This new iodination agent, when diazotized, does not enter the cell interior, and labels only outer membrane proteins. It may also be useful in fractionation of subcellular particulates and studies designed to follow the fate of autologous viable cells *in vivo*.

Iodosulfanilic acid [^{125}I] Labeling Kit
(including reagents for diazotization)
n-Propanol:water solution, 1:1, in Combi-vial
> 1000Ci/mmol NEX-121

Not for use in humans or clinical diagnosis

Protein Iodination
Bolton-Hunter Reagent [^{125}I]

Available at two specific activities: ~1500Ci/mmol, ~4000Ci/mmol. The Bolton-Hunter Reagent is now widely used to circumvent the difficulties associated with iodination of labile antigens and polypeptides. Conjugation of the iodinated ester to terminal or lysine amino groups is accomplished with minimal manipulation and under extremely mild conditions.

Bolton-Hunter Reagent [^{125}I]
(In benzene solution in Combi-V-Vial)
~1500Ci/mmol NEX-120
Prepared fresh weekly.
~4000Ci/mmol NEX-120H
Prepared every two weeks.

Not for use in humans or clinical diagnosis

Interpretation of the Southern California uplift in terms of the dilatancy hypothesis

Max Wyss

Cooperative Institute for Research in Environmental Sciences, University of Colorado/NOAA, Boulder, Colorado 80309

The 25-cm uplift in Southern California is interpreted as being due to dilatancy of the crust, which started in 1961 along the San Andreas fault and spread laterally during 1964–69. The San Fernando earthquake of 1971 occurred in part of the dilatant volume, and is interpreted as a sideshow of a future repetition of the 1857 San Andreas break, which had a magnitude > 8.

AN area of at least 12,000 km^2 was uplifted aseismically in the early 1960s in Southern California[1]. The uplift was centred on the San Andreas Fault, where it reached a maximum of over 25 cm near Palmdale, 60 km north of Los Angeles. The portion of the San Andreas Fault that lies within the 15-cm uplift contour comprises the southern half of the last major earthquake in Southern California, the 1857 rupture, which had a length of about 350 km (ref. 2). The segment of the San Andreas Fault that broke in 1857 exhibited conspicuously low seismicity during the last 40 yr (ref. 3). This section is considered to be a mature seismic gap, which is expected to be closed by a large quake sometime in the future.

Castle *et al.*[1] offered two hypotheses to explain the portion of the aseismic uplift in the San Fernando area: (1) a north–south contractional strain effect coupled with creep on a deep part of the San Fernando Fault, or (2) a dilatancy effect. Thatcher[4], elaborating on the first hypothesis, proposed that the north-dipping San Fernando Fault reaches a depth of about 50 km, cutting below the San Andreas and extending north of it, and he suggested that aseismic creep started at the deepest part of this thrust fault and propagated upwards, causing the uplift and culminating in the 1971 San Fernando earthquake.

We formulate here a dilatancy hypothesis to explain the observed uplift and to show that this alternative has some advantages that may make it more plausible than the creep hypothesis.

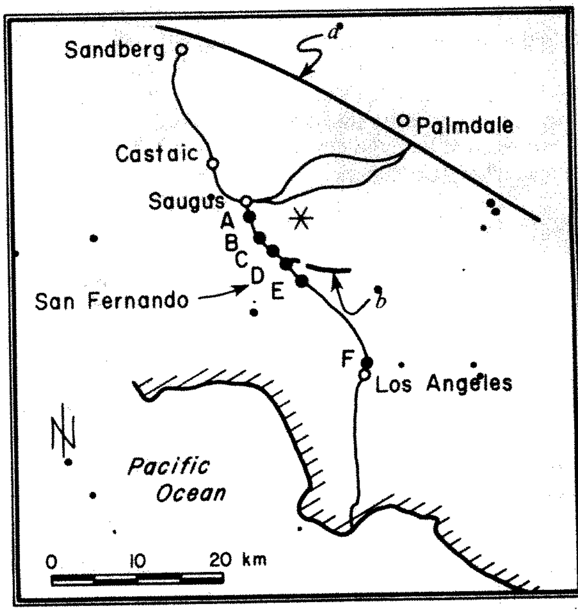
Uplift data

Figure 1 shows the location of the two levelling lines discussed by Castle *et al.*[1]: Los Angeles–Saugus–Palmdale, and Los Angeles–Saugus–Sandberg. Figure 2 shows the uplift as a function of time at the points A–F (Fig. 1), which straddle the 1971 San Fernando thrust fault (Fig. 1). The similarity of the uplift history before the San Fernando earthquake (Fig. 2) and the famous uplift before the Niigata earthquake[5] is striking. A 35–40-yr period of stability is followed by sudden uplift, which again is followed by a few years of quiescence. It is important to note that points A, B and C are located north of the San Fernando Fault on the upthrust block, and points D, E and F south of it on the downthrust block. All of these points were uplifted before the San Fernando earthquake. This feature is required by the dilatancy hypothesis, and it is opposite to what is expected by the creep hypothesis, as will be discussed below.

In Fig. 2 it is also evident that the uplift started earlier in the north (points A, B), and was larger there, than in the south (points E, F). This sequence is examined in more detail in Fig. 3, which shows the uplift along the Palmdale–Saugus–Los Angeles traverse. The picture is that of an uplift disturbance initiated in the north (at the San Andreas) and spreading south with the San Fernando earthquake as a preliminary culmination. A tiltmeter located anywhere along this traverse would have recorded a south tilt at first (1961–64), and then a north tilt (1964–65), as was noted by Thatcher[4] for the traverse Sandberg–Saugus.

The Sandberg–Saugus–Los Angeles traverse is shown in Fig. 4. For this traverse no data were available for the period 1961–64. During 1964–65, the uplift was concentrated in the middle to northern part of the traverse as it was for the other levelling line in the same period of time (Fig. 3). Next, the southern and northern portions were uplifted between 1965 and 1968. The middle portion stayed at the same elevation during this interval, but it caught up the next year, 1968–69 (Fig. 4*c*). The entire

Fig. 1 Map showing the location of levelling lines with respect to the San Andreas (*a*) and San Fernando (*b*) faults. *, 1971 epicentre. Uplift is measured with respect to the coastal point of the traverse (tidal 8) as constant[1].



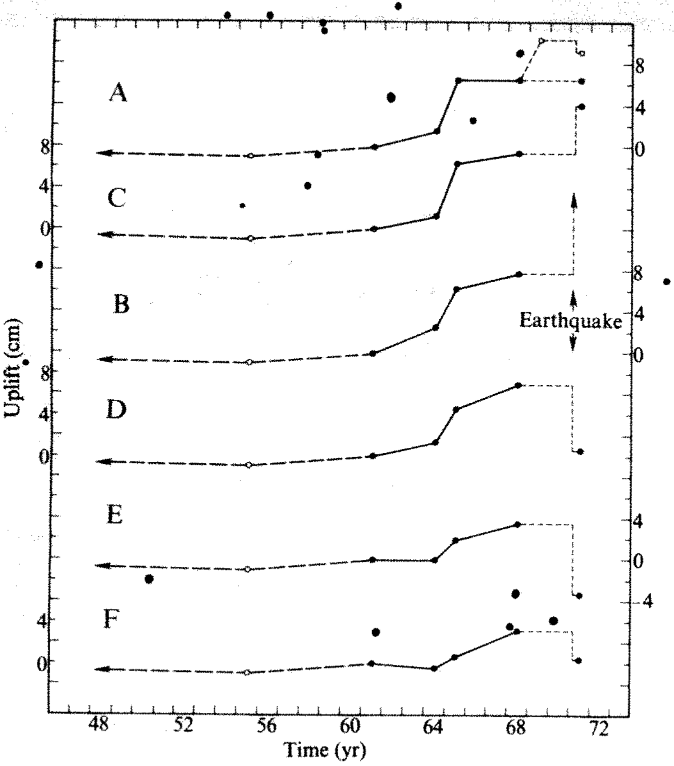


Fig. 2 Uplift as a function of time for three points each on the upthrust (A, B, C) and downthrust (D, E, F) blocks of the San Fernando quake. The data from 1961–71 are from Castle *et al.*[1]. Before that, two measurements in 1926 (→) and 1955 (○) were the same, within a couple of cm, as those in 1961 (R. O. Castle, personal communication).

southern part of the traverse may also have been uplifted a further substantial amount in 1968–69; however, there are no data along this portion of the surveying line. The possibility of this additional surge in 1968–69 is indicated in Fig. 2 for point A as alternative. Figure 4*d* shows the elevations along the traverse after the 1971 San Fernando earthquake.

Interpretation

From Figs 2–4 it is evident that uplift before the San Fernando earthquake occurred both north and south of its surface rupture, suggesting that dilatancy preceded this earthquake. Dilatancy is the volume increase exhibited by sands and rocks under large deviatoric stresses[6,7], is measured as the deviation of the volume change, $\Delta V/V$, from the linear elastic behaviour, and is due to increased pore and crack volume. In the laboratory, dilatancy precedes rock failure. It was proposed that dilatancy in the crust is the cause of observed changes of crustal properties before some shallow earthquakes[8–13].

If we assume that the entire uplift was due to dilatancy, we may calculate the volume change from[14]

$$\Delta V/V \approx h/r$$

where h is the uplift and r is half the depth to which dilatancy extended. I will assume that only the 'brittle' part of the crust (the top 15 km which contain earthquakes) can become dilatant[15]. Under this assumption, a 15-cm uplift between 1961 and 1964 near the San Andreas implies that $\Delta V/V = 2\times10^{-5}$, which is schematically indicated in Figs 3*a* and 4*a* by dark shading. The spreading of increased uplift away from the San Andreas towards San Fernando is interpreted as being due to an increased amount of dilatancy, spreading through the crust, away from the San Andreas (see crustal cross sections as a function of time in Figs 3 and 4). Finally, the San Fernando earthquake locally released the deviatoric stress, and dilatancy disappeared below the southern portion of the profile. The crust within 30 km of the San Andreas remained dilatant, in this interpretation, and the repetition of the 1857 earthquake will reduce this portion of the crust back to normal. This model also accounts for the tilt reversal, which was presented as one of the main supporting facts for the creep hypothesis[4], and is in agreement with laboratory observations[16], where localised bulges due to dilatancy are observed to migrate to different parts of the rock sample, and, in the final phase; begin to concentrate along the subsequent fracture plane.

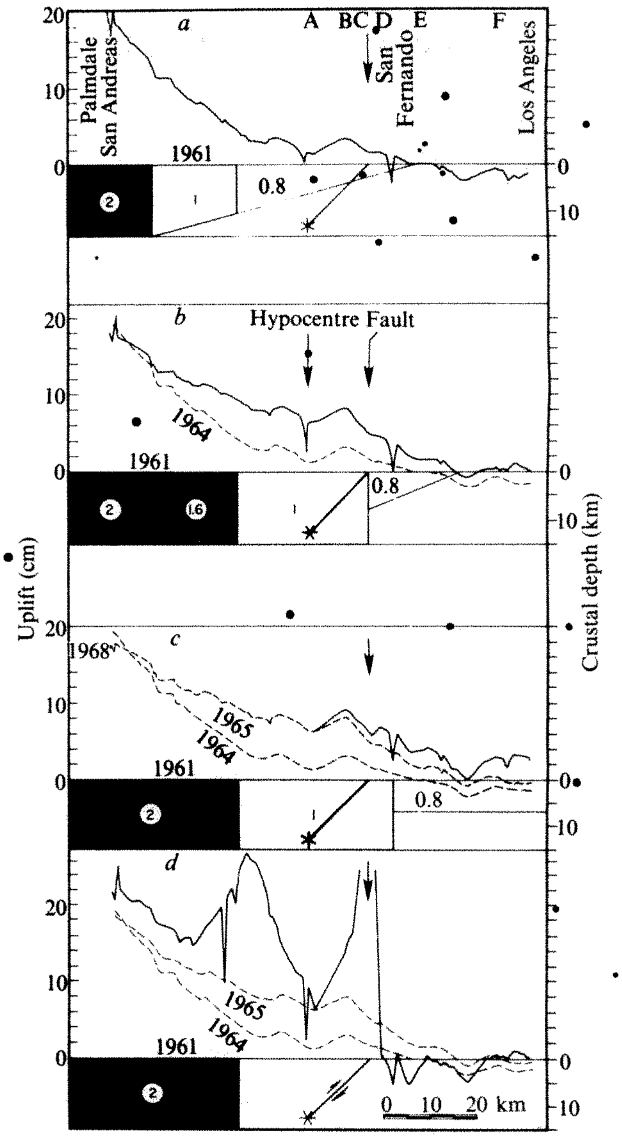

Fig. 3 Uplift along the Palmdale–Saugus–Los Angeles traverse from Castle *et al.*[1]. The 1961 level was taken as reference with respect to which the 1964 (*a*), 1965 (*b*), 1968 (*c*) and 1971 (*d*) levels are shown. The state of the crust below the traverse is shown in each time frame. The number in the crust indicates the volume increase in units of 10^{-5} if it is assumed that thickness of the dilated crust is that indicated by the stippled area. In the 1971 curve the hump north of the hypocentre is due to the corner in this profile which re-approaches the epicentre at this point. *a*, Uplift between 1961 and 1964, decreasing gradually from 20 cm in the north (at the San Andreas) to zero in the south (San Fernando). *b*, Uplift in 1965 (—) with respect to the 1961 level. The 1964 uplift is retained (- - -) for comparison. No further uplift occurred between 1964 and 1965 in the north, but a substantial amount was added in the south, near the future San Fernando rupture. *c*, Uplift in 1968, again being concentrated even further south than the 1964–65 episode. Finally, after the 1971 San Fernando earthquake (*d*), the previously uplifted area south of the rupture was now below the initial level, north of the rupture large co-seismic uplift occurred, and along the San Andreas the uplift was essentially unchanged.

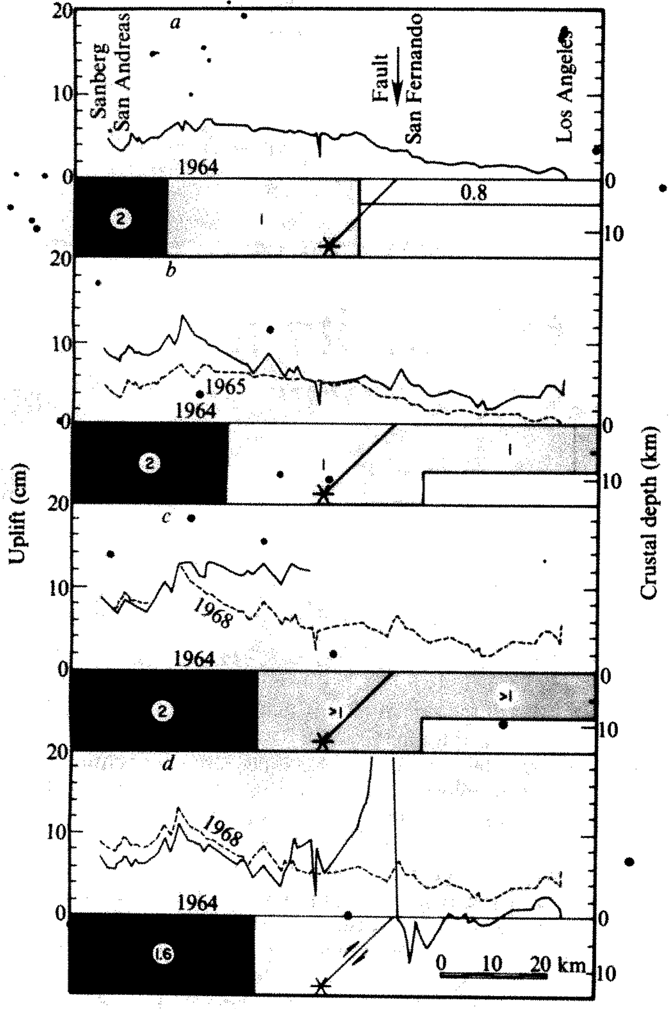

Fig. 4 Uplift along the Sandberg–Saugus–Los Angeles traverse from Castle *et al.*[1]. The reference level is that of 1964. Levels are shown for: *a*, 1965; *b*, 1968; *c*, 1969; *d*, 1971. Uplift episodes are again approximately interpreted by an increasingly dilated crust. The amount of volume increase is again given in units of 10^{-5} with the assumption that in the time interval 1961–64, for which no data were available, an uplift of 10 cm occurred near the San Andreas, decreasing to zero at San Fernando. The basis for this assumption was the uplift between 1961–64 on the other profile (Fig. 3), but divided by two so as to be on the safe side.

Why should dilatancy begin at the San Andreas, and why should it persist there at a time when rupture occurred in a less dilated volume? Geodetic measurements in California suggest that strain accumulation may be concentrated along the San Andreas Fault[17,22]. I will therefore assume that stresses are concentrated along the fault and hypothesise that the deviatoric stress *C′*, at which dilatancy appears[7], was first reached near the San Andreas. As further deviatoric stress was accumulating, *C′* was exceeded in a widening crustal volume. Also, as Thatcher[4] showed, the stress normal to the local trend of the San Andreas was increasing, thus locking the fault. The shear stress along thrust faults in the area increased, and so it follows that local thrust faults like the San Fernando Fault may fail first.

I also note that Thatcher[4] has shown that the surface stress was everywhere compressive perpendicular to the uplift contours. This observation is in agreement with the laboratory measurements on dilating samples. Nearly always the stresses on the outside of the buckling samples are compressive, that is, the samples continue to become shortened throughout the experiments up to failure, even though dilatancy occurs.

Another interesting point is that there were two surges of uplift, one in 1961–65 and the other in 1968–69. The latter may have occurred only in the middle part of the profile, including the epicentre region of the San Fernando earthquake. The second phase of uplift could have been due either to the pore fluid pressure increase expected as a corollary of the wet dilatancy hypothesis[18], or to precursory creep, as required by the dry dilatancy models.

Finally, the speed with which the uplift occurred might be taken to support the creep hypothesis. Laboratory results on jointed rocks[19] suggest, however, that in crustal conditions, dilatancy uplift of a few centimetres could occur within a few months. Several years before earthquakes in Peru, Japan and California, approximately 6 cm of aseismic uplift occurred which accumulated within less than half a year[20].

Conclusions

The Southern California uplift can be explained by a dilatancy model, as well as by a creep model. In fact, aseismic uplift, the only direct evidence for dilatancy, can always be explained alternatively by a creep model, unless gravity observations are available together with uplift data.

Thatcher's[4] creep model gives major importance to the transverse range. Its advantage is that it explains the observed asymmetry of the Southern California uplift (steeper to the south). Its disadvantages are that it does not explain the uplift south of the San Fernando rupture. The continuation of Thatcher's Fig. 4*b* to the south would have to show curves 1 and 2 below zero level, when the data show that this area was subject to uplift, not subsidence. Also, it does not explain why the uplift is centred on the San Andreas Fault, and it does not explain the Niigata data in a straightforward way.

The dilatancy model gives major importance to the San Andreas Fault as a plate boundary concentrating stresses. The transverse range follows from the bend in the San Andreas. This model's advantages are that it explains the entire uplift, including the uplift south of San Fernando. Also, it agrees with the interpretations of anomalous travel times[13] and anomalous seismicity[24] before the San Fernando earthquake. The disadvantage of this hypothesis is that it does not explain the asymmetry of the uplift. It is quite plausible, however, that the rheological contrast between the granitic transverse range and the deep sedimentary basin of Los Angeles may cause a different dilatancy response to the same overall stress.

A test for accepting or rejecting one of the models could be found in the seismic wave velocities during the early and mid 1960s. The dilatancy model requires that in the early stage a velocity decrease should have occurred. From 1973 on, no substantial velocity anomalies are observed in the general area of the uplift[21]. If ground water has returned to fill cracks and pores, however, the anomaly would have disappeared by now. Another test lies in the future developments in the area. The creep hypothesis was developed on the example of a very small feature, the 20 km long San Fernando rupture. If the creep hypothesis is correct, it should apply to the entire length of the uplift, which is at least 200 km long. The corollary is that ten more San Fernando-type thrusts should occur in the future along the transverse range front. If the dilatancy hypothesis is correct, medium-sized thrusts are not excluded, but the San Andreas would be expected to produce a major quake with some subsidence following it.

I feel that neither the creep nor the dilatancy hypothesis is strong enough to be accepted at this point. While the uplift south of San Fernando is best explained by dilatancy, it may be quite likely that premonitory creep occurred on a deeper part of the San Fernando fault, as required by the dry dilatancy models.

Hydrothermal fluids of seawater salinity in ophiolitic sulphide ore deposits in Cyprus

E. T. C. Spooner & C. J. Bray

Department of Geology and Mineralogy, Parks Road, Oxford, UK

Freezing points of fluid inclusions in vein quartz intergrown with sulphides from ophiolitic cupriferous pyrite ore deposits in Cyprus indicate a hydrothermal fluid of seawater salinity, and confirm the hypothesis of metal transport in hot seawater. It is therefore suggested that the economic potential of oceanic crust layer 2 is probably negligible.

EXISTING information suggests that hot seawater leached, transported and deposited metals (Fe, Cu, Zn, Pb, Ni, Co, Ag and Au) from solution to form the sulphide ore deposits in the Upper Cretaceous ophiolitic rocks of the Troodos Complex, Cyprus[1–4]. The evidence is based principally on the use of isotopes (^{87}Sr/^{86}Sr, D/H, ^{18}O/^{16}O and ^{34}S/^{32}S) as geochemical tracers and is consistent with a model for hydrothermal metamorphism and mineralisation which involved convection of seawater within the ~2-km thick permeable layer of pillow lavas and dykes which forms the upper part of the ophiolitic sequence (Fig. 1)[1–5]. By estimation of a Rayleigh number Spooner[3] has shown that the fluid dynamic conditions necessary for vigorous hydrothermal convection were satisfied.

The ore deposits, which formed in the submarine environment, generally consist of a lens of massive sulphides (pyrite – chalcopyrite ± sphalerite ± marcasite ± galena) intercalated within the pillow lava sequence[6–10]. This is underlain by a pipe-shaped mineralised stockwork extending downwards into the dyke complex (Fig. 1)[6–10]. They have been worked for copper since pre-classical times, for high quality pyrite used in the manufacture of sulphuric acid[11] and for minor quantities of gold and silver, which occur in 'Devil's Mud' only, found in the zone of supergene alteration[6]. Approximately 20 deposits containing on average ~1 million tonnes ore of variable copper content have been worked on the island. The largest and richest was Mavrovouni, which contained ~15 million tonnes ore grading between 3.5 and 4.5 weight % Cu (ref. 6). Limni—the largest working mine at present—produces ~450,000 tonnes ore per annum at a mean grade of ~0.85% Cu (refs 12,13).

The object of this article is to describe a test of the hypothesis of metal transport in hot seawater. This has involved determination of depressions of the freezing point of samples of the ore fluid which occur as small inclusions in minerals from the sulphide deposits. This colligative property, a reflection of the salinity of the solution, is then compared with the freezing point of seawater.

Experimental technique

The fluid inclusions were examined in thin sections of rock a few millimetres in size which were polished on both sides down to a thickness of ~60 µm using 1–0.3-µm sized alumina particles on a vibratory polishing machine. The slivers were prepared from ~1-mm thick slices of rock containing minerals with fluid inclusions which were mounted on glass slides using Lakeside resin. The thin sections were floated off by soaking in absolute alcohol for 1–3 days, and pre-selected areas of inclusions were cut out. Microthermometric measurements were then conducted on a Chaix-Meca heating-freezing (−180 °C to +600 °C) stage[14] mounted on a Leitz Ortholux II microscope fitted with ×32 and ×50 UMK objective lenses and ×25 binocular eyepieces. This facilitated examination of inclusions down to a few micrometres in size. Measurements were carried out on about 20 inclusions per sample. The inclusions were pre-selected in order to obtain an approximately random sample.

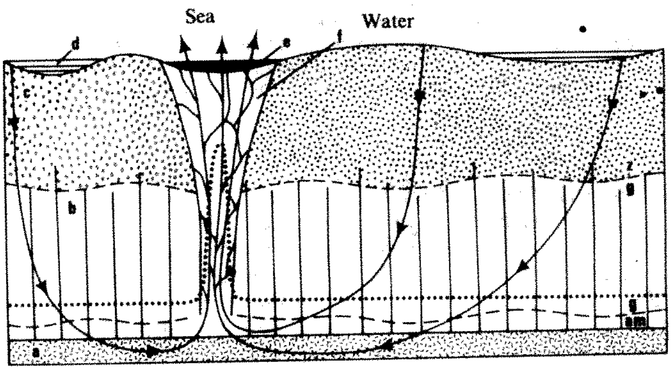

Fig. 1 Schematic diagram of model of hydrothermal convection, metamorphism and mass transfer within the ophiolitic rocks of the Troodos Massif, Cyprus. General metamorphism[37] occurred in zones of recharge flow, whereas formation of the cupriferous pyrite ore deposits[6–10] occurred in the discharge zones. Precipitation of Fe/Mn enriched sediments ('umbers')[38–40] was also probably a consequence of discharge of hot metalliferous solutions[1,38]. a, Gabbros, metagabbro and variably altered trondhjemite; b, sheeted dyke complex; c, pillow lavas; d, umbers; e, massive sulphide ore; f, mineralised stockwork. Dashed lines approximate to metamorphic boundaries between zeolite facies (z), greenschist facies (g) and amphibolite facies (am). Continuous lines are schematic flow lines for hydrothermal convection; dotted line is approximate form of an isotherm produced by convection.

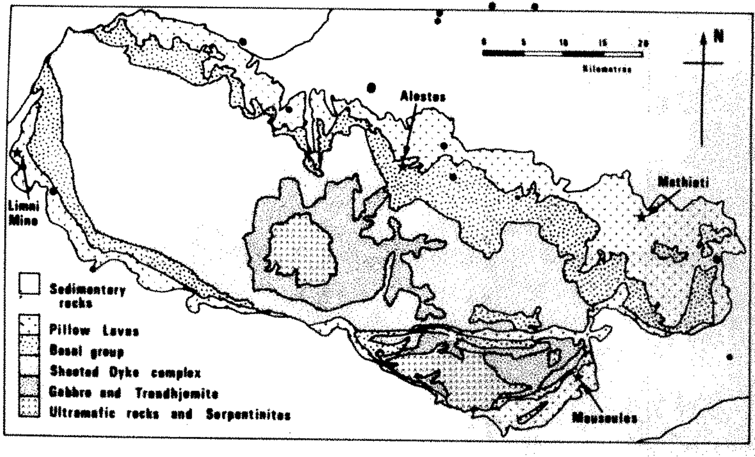

Fig. 2 Simplified geological map of the Troodos Massif, Cyprus (modified after the Cyprus Geological Survey map) showing the locations of the mines from which samples were obtained for fluid inclusion and strontium isotopic studies[21].

Pure nitrogen gas, which was passed through a heat exchanger in liquid nitrogen, was used to control cooling. The sample was taken down to −50 °C to ensure freezing of the inclusions since the fluid in the inclusions shows pronounced supercooling effects. Most inclusions froze at ~−30 °C. The sample was allowed to warm up to a temperature 1–3 °C below the freezing point of the inclusions and was then usually refrozen to −21 °C. This promoted growth of observable single crystals of ice and often produced a displacement of the vapour bubble from its equilibrium position. The temperature of ice disappearance was then measured in large inclusions (~50–100 μm). In smaller inclusions ice was not in general visible[15] because of the small refractive index difference between ice and water in dilute solutions. The temperature at which the vapour bubble returned to its original shape and position was then recorded. The freezing points of the inclusions were close to 0 °C, so the apparatus could be precisely calibrated against the freezing point of deionised water. This was done by squirting a small quantity of vapour from deionised water over a sample at low temperature, to produce small crystals of ice immediately above fluid inclusions. The freezing points of the inclusions and the frost on the sample surface were then measured sequentially. Hence, the freezing points of the fluid inclusions and the deionised water were determined in identical experimental conditions. The result of 12 such measurements indicated that the recorded fluid inclusion freezing points had to be increased by 0.2 °C. The estimated reproducibility of any given fluid inclusion freezing point is ±0.2 °C for the particular temperature range encountered.

When fluid inclusions which were formed at temperatures greater than ~50 °C cool down naturally vapour bubbles nucleate and grow, because the coefficient of thermal contraction of the liquid is greater than that of the enclosing solid. The temperature at which the vapour bubble disappears during controlled heating may then be determined in order to obtain an homogenisation temperature, which, if pressure corrected when necessary[16,17], gives a temperature of formation of the fluid inclusion. Such homogenisation temperatures are readily measured since the small vapour bubble goes into a state of progressively more violent Brownian motion just before its disappearance. The apparatus was calibrated using substances of known melting point[14,15]. The accuracy of any given measurement was controlled by the observed range of temperature over which the standards melted, and is considered to be ±2 °C for the temperature range encountered.

Fluid inclusion freezing points

As the primary salinity of the hydrothermal hot water was the subject of interest, it was necessary to avoid samples which could have contained inclusions formed from a boiling fluid. Hence, material was examined from three relatively deep stockworks, in which pressure would have been highest. At Limni mine (Fig. 2) the main ore deposit occurs as a stockwork developed in pillow lavas[13,18]. Samples were examined from the core of the deposit, where copper grades of 1–3% occur. In the SE corner of the opencast pit pyritised and hydrothermally metamorphosed Sheeted Dyke Complex occurs as part of an upfaulted block. This locality is particularly valuable because it probably constitutes the best exposure of the deepest part of a stockwork anywhere in Cyprus. The metamorphic mineral paragenesis differs from that typical of higher level stockworks (quartz–chlorite–illite–sulphides[10]) and is characteristic of the greenschist facies (quartz–albite–chlorite–epidote–actinolite–sphene–pyrite). The third locality chosen was Alestos (Fig. 2) which consists of a small cupriferous pyrite stockwork developed in the zone transitional between sheeted dykes and pillow lavas (the 'Basal Group'). Three samples from each of these localities were studied.

Fluid inclusions were examined in vein quartz intimately intergrown with sulphides, which contains high densities of inclusions. The inclusions are of variable shape, some being very irregular in outline whereas others show well defined negative crystal morphologies. They are in general between 5 and 100 μm in size (Fig. 3*a*). Boiling during ore formation is usually indicated by the presence of two co-existing types of inclusion—one type, with a high vapour–liquid ratio, corresponding to 'steam' and the other, with a lower vapour–liquid ratio, corresponding to 'liquid'. The former homogenise in the gas phase, the latter in the liquid phase. Such evidence for boiling was searched for in these samples and not found. Most inclusions are of the simple two phase type, but a third solid phase was quite frequently present in larger inclusions. These daughter crystals occur as highly birefringent feathery aggregates similar in appearance to dawsonite ($NaAl\,CO_3\,(OH)_2$)[19] (Fig. 3*a*). The high birefringence suggests that they are some type of carbonate or sulphate.

The freezing points and homogenisation temperatures, most of which have been determined on the same inclusions, are given in Table 1 and all the freezing point data are presented as a frequency polygon in Fig. 4.

The inclusions are clearly of hydrothermal origin since their homogenisation temperatures are universally high. The data for the nine samples vary from 301±23 °C (21 measurements) to 351±4 °C (20 measurements). Most inclusions show no obvious geometrical relationships which can be used to indicate that they are primary (formed during growth of a crystal) or secondary (formed after growth). It could be argued, therefore, that they might be unrepresentative of the fluid which actually precipitated the ore minerals. This is shown not to be the case from examination of sample CY/75/39 from the main Limni

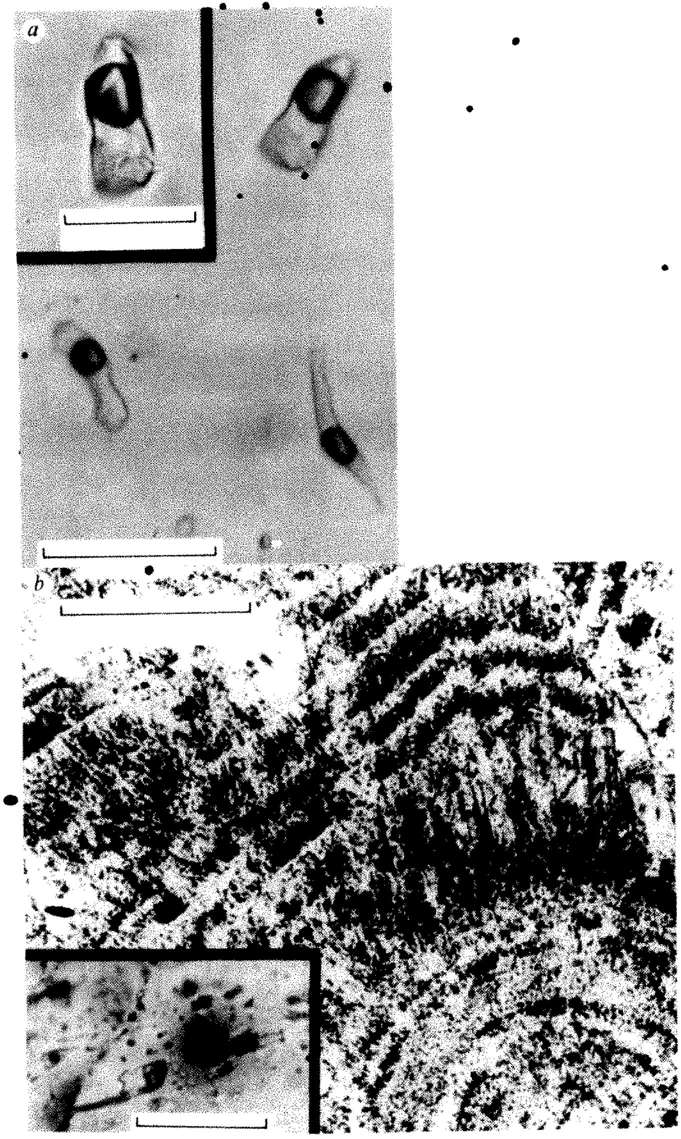

Fig. 3 *a*, Typical fluid inclusions in quartz from Cyprus sulphide ore deposit material (sample CY/75/38; Limni main stockwork; scale bar 30 μm). Central upper inclusion; T_H = 360 °C, T_F = −2.7 °C. Lower left inclusion; T_H = 313 °C, T_F = 2.1 °C. Lower right inclusion; T_H = 361 °C, T_F = −2.1 °C. Inset shows daughter crystals (? carbonate or sulphate) in the central upper inclusion, scale bar 20 μm. *b*, Primary fluid inclusions in vein quartz from the Limni main stockwork (sample CY/75/39). The inclusions define growth zones in the quartz crystal and are elongate parallel to the direction of growth. Therefore, according to normal geometrical criteria[16,17], they are considered to have formed during crystal precipitation. Since the vein quartz is intimately intergrown with sulphides the fluids in these inclusions are samples of the sulphide ore forming solution; scale bar 200 μm. Inset shows two primary inclusions in detail; scale bar 35 μm. Left inclusion; T_H = 307 °C, T_F = −2.0 °C. Right inclusion; T_H = 309 °C, T_F = −2.0 °C.

stockwork. This was the only sample to contain well defined primary inclusions clearly related to growth zones in quartz (see Fig. 3*b*). The results of measurements on these primaries and on inclusions of the more general type agree within 1σ (Table 1). Since the vein quartz is intimately intergrown with sulphides the fluid inclusion data from this sample, and all other samples, apply to the process of sulphide ore deposition itself.

The depressions of the freezing point of the fluid inclusions relative to pure water were found to be small (−1.6±0.2 °C to −2.4±0.4 °C), and therefore indicate that the hydrothermal ore forming fluid was a relatively dilute solution (2.7–4.0 equivalent weight % NaCl). The data for different samples are all statistically indistinguishable within 2σ limits, and most are indistinguishable within 1σ limits. Taking into account an accuracy of ±0.2 °C for any given measurement, the frequency polygon for all the 205 determinations (Fig. 4) shows a unimodal and symmetrical distribution about a mean value of −1.9 °C. The standard deviation is ±0.4 °C.

This freezing point is statistically indistinguishable from that of sea water. The salinity of sea water in the open ocean varies from 32 to 37.5‰ (ref. 20). In small ocean basins such as the Mediterranean and the Red Sea it rises to 41‰ (ref. 20). This produces a freezing point range for seawater of from −1.7 °C to −2.2 °C. Average seawater with a salinity of 35‰ has a freezing point of −1.9 °C. Hence, it is clear that a hydrothermal fluid identical to seawater in its salinity formed the ophiolitic sulphide ore deposits of Cyprus. That this fluid was actually of seawater origin is indicated by the stable isotope work of Heaton and Sheppard[4] and confirmed by the strontium isotope ratios reported by Chapman and Spooner[21], which demonstrate ^{87}Sr enrichment of mineralised material up to Upper Cretaceous seawater ^{87}Sr/^{86}Sr values. The hypothesis of metal leaching and transport by hot seawater is, therefore, verified.

The data may be compared with freezing points of fluid inclusions in minerals from greenschist facies metabasic rocks dredged from the Atlantic Ocean floor[15]. Since the mean homogenisation temperatures of six samples containing secondary actinolite ± epidote range from 219 °C to 324 °C, the fluids in the inclusions are clearly hydrothermal in origin. The mean of 77 freezing point values given by Jehl[15] for these samples is −2.0 °C, and the

Fig. 4 Frequency polygon of the 205 freezing point measurements of fluid inclusions in vein quartz from ophiolitic sulphide ore deposits, Cyprus, compared with the freezing points of seawater[20] and of fluid inclusions in metabasic rocks containing actinolite ± epidote dredged from the Atlantic Ocean floor[15]. Mean freezing point −1.9 °C, s.d. ±0.4 °C.

Cytobiologie, a Journal for experimental cell research, will publish papers in English, German and French languages on the structure, function and macromolecular organization of cells and cell components.

Aspects of cellular dynamics, morphogenesis, cytochemistry, biochemistry and molecular biology in relation to cytological research are preferred fields for contributions in which morphological, physiological, biochemical and biophysical data are correlated.

The journal will also publish short communications, abstracts of meetings, book reviews and review articles (upon request). Papers will be published free of charge within five months and short communications within eight to twelve weeks.

Don't settle for half the literature loaf.

Now you can get the "whole" loaf with **BioResearch Index (BioI)**. Certainly **BIOSIS** selects, abstracts and indexes more than 140,000 primary journal articles every year . . . but there's more to life science literature than that. Much more.

In **BioI** we meticulously search and report on—
- Research Communications • Notes
- Reports • Symposia • Proceedings
- Meeting Abstracts • Monographs

These add up to 100,000 items which appear each month in **BioI** from thousands of sources.

You can leisurely browse the contents pages or quickly find special interests indexed by—
- Subject • Author • Field of Interest
- Organism (Biosystematic/Generic).

	Kuroko sulphide ore deposits of Japan[23]	−1.8 to −3.7‡	146–189‡
	Sea water[20]	−1.7 to −2.2§	
	Average sea water (salinity = 35‰)	−1.9	

*Mean ± s.d.; figures in parentheses are numbers of measurements.

†These data were obtained from six samples (GA 12-14, V27-DR. 11-K1, G12-19, D1-11, G.12-A and AT150-20-1) listed by Jehl[15]. The number of measurements refers to the number of values quoted for each sample. The temperature range refers to the range of the means of the homogenisation temperatures listed for each sample. A wider range of salinities was recorded, but from material not from the greenschist facies[15,41].

‡This freezing point range was obtained from about 560 measurements on 51 samples from the Yunosawa deposit, Furutobe mine[23]. Fluid inclusions were studied in barite, sphalerite and fluorite. 34 samples were from siliceous ore and 17 from black ore. The homogenisation temperature range given refers to the range of the means of 85 determinations on seven samples (five from siliceous ore and two from black ore) also from the Yunosawa deposit[23].

§This range was obtained from the salinity variation in the open ocean (32–37.5‰) and from the salinities found in small ocean basins such as the Mediterranean (37–40‰) and the Red Sea (40–41‰)[20].

standard deviation is ±0.4 °C. This value is also statistically indistinguishable from that of seawater. These samples would probably have come from the recharge parts of ocean-floor hydrothermal convection systems, whereas the samples from the Cyprus ore deposits were formed in discharge zones. The data show, therefore, that seawater does not detectably change bulk composition sufficiently to affect its freezing point during interaction with basic igneous rocks at elevated temperature.

The freezing points of the Cyprus ore deposit fluid inclusions may also be compared with data from the Kuroko polymetallic sulphide deposits of Japan. These are also of submarine origin but formed in association with rhyolite domes rather than basic igneous rocks. Stable isotope ratios (δD and $\delta^{18}O$) of fluids from inclusions in sulphides in these deposits suggest that the ore fluid was also predominantly of seawater origin[22]. The range of ~560 measurements of freezing points of fluid inclusions in barite, sphalerite and fluorite from the Yunosawa deposit, Furutobe mine has been reported[23] as −1.8 °C to −3.7 °C (34 samples were from siliceous ore and 17 from black ore). This is very similar to the total range of fluid inclusion freezing points from the Cyprus ore deposits (−1.2 °C to −3.2 °C; Fig. 4). Hence, the effects on the bulk composition of seawater during water–rock interaction in the Cyprus and Kuroko environments were essentially the same.

Economic potential of oceanic crust layer 2

This information on fluid inclusion salinities in Cyprus ore deposits shows that when ordinary seawater interacts at elevated temperature with ordinary basaltic rock, sulphide deposits can be formed. Hence, regardless of whether the ophiolitic sequence of the Troodos Complex, Cyprus, is or is not a representative tectonically emplaced fragment of oceanic crust and upper mantle[24–26], the ore deposits within it may probably be taken as characteristic of the type of ore deposit formed during seawater circulation[1,27–30] within spreading oceanic ridges. This convective process is now thought to occur on a massive scale, and is probably the main hydrothermal ore forming process which affects the upper part of the sequence of igneous rocks of the oceanic crust (layer 2).

Hence, the sizes and metal contents of the Cyprus deposits may be used to assess the possible economic significance of oceanic crust layer 2. As mentioned above, these deposits are essentially small (0.5–15 million tonnes), occasionally relative rich copper ore bodies (~0.5–~4% Cu), which contain no other metals of economic importance[6-13]. To place them in context, they may be compared with a class of hydrothermal ore deposit which supplies the largest contribution (~45%) to world copper production—the porphyry copper deposits[31]. The average size of porphyry coppers is approximately 150 million tonnes, and they normally contain greater than 0.5% copper (average = ~0.8% Cu) which is often associated with economically significant quantities of molybdenum or gold[32]. They are therefore on average 1–2 orders of magnitude larger than Cyprus-type deposits, and can be much bigger. For example, the largest worked porphyry copper deposit (Bougainville, Territory of Papua and New Guinea) contains 900 million tonnes ore grading 0.48% Cu and 0.6 p.p.m. Au (ref. 33). The largest known porphyry copper (Cerro Colorado, Panama) contains at least 2,000 million tonnes ore grading 0.61% Cu (ref. 34). These data show, therefore, that Cyprus-type deposits are not particularly economically significant even when exposed on land. Also, an additional source of supply of copper in the future will probably be obtainable from the 'manganese nodules' which occur on the ocean floor[35,36].

Hence, bearing in mind the technological difficulties of ocean floor mining, this brief assessment of the ophiolitic sulphide ore deposits of Cyprus suggests that it is unlikely that layer 2 of the oceanic crust contains economically significant mineral deposits.

We thank Professor E. A. Vincent and Dr E. J. W. Whittaker for support, Professor B. Poty and the Chaix-Meca Co. for assistance in setting up the microthermometric apparatus, Mr R. Holland for perfecting a preparation technique for fluid inclusion thin sections and Drs S. Moorbath, A. H. Rankin and T. J. Shepherd. E.T.C.S. thanks Mr Y. HjiStavrinou, Dr G. Constantinou, Mr T. O. Trennery and the management of Limni mine for their cooperation. C.J.B. acknowledges an NERC grant.

Subsurface movements of stone artefacts and their implications for the prehistory of Central Africa

D. Cahen & J. Moeyersons
Musée royal de l'Afrique centrale, B—1980 Tervuren, Belgium

The general and systematic character, in Central Africa, of a postsedimentary process of vertical redistribution of stone artefacts buried in a Kalahari sand mantle is strongly suggested. This invalidates the prehistoric nomenclature and chronology of this area and may have implications on the palaeoclimatological interpretation of stone-line profiles.

THE immense area occupied by the Zaïre or Congo river basin in the heart of Africa is still very little known from the archaeological point of view. The present-day nomenclature of the post-Acheulian prehistoric industries of Central Africa is based on very few excavations and on some systematic surface collections, essentially made in the regions of Kinshasa, in Zaïre[1] and of Lunda, in north-eastern Angola[2]. This nomenclature presents a somewhat conjectural and theoretical character as it consists only of a compilation of various observations made at different sites. Only at the site of the Gombe Point (formerly Kalina Point) at Kinshasa, which had been excavated[3-4] as early as 1925, was a complete post-Acheulian succession supposed to exist.

In 1968, a Symposium held at Tervuren, Belgium, under the auspices of the Commission of Nomenclature and Terminology of the Pan-African Congress on Prehistory and Quaternary Studies expressed the wish that new excavations should be undertaken at Gombe Point to determine and date this prehistoric succession[5]. These new excavations[6] were performed in 1973 and 1974. Fairly quickly, the conclusion was reached that this new research raised a series of problems much more important than the mere revision of the prehistoric nomenclature as it now seems that all the evidence, previously considered to be established, should be questioned.

Evidence from the Gombe excavations

At Gombe, the stone artefacts are distributed irregularly at all depths but with a considerable concentration (45%–95% of the total population) near the base of a homogeneous sand–silt–clay mantle, 3–5 m thick, which overlies a silicified bed-rock. This mantle is derived from the Red Sands of the Upper Kalahari, which cover the surrounding

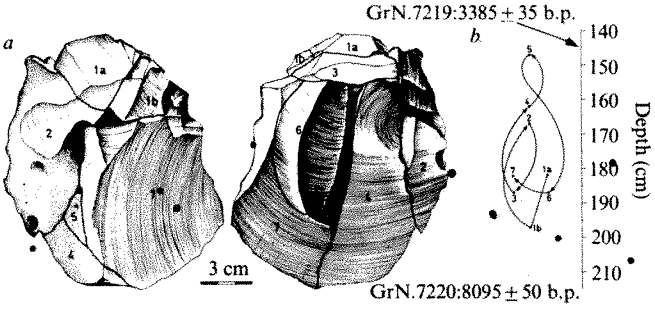
highlands[7]. This kind of irregular distribution of artefacts and this type of sediment are typical for the great majority of the open air archaeological sites known in the southern part of the Zaïre river basin and on which the knowledge of the Prehistory of Central Africa relies[8].

A study of the typological and quantitative distribution of the artefacts according to depth seemed to suggest the existence of different prehistoric industries: in the different trenches, various assemblages of characteristic artefacts were found in more or less the same order from the top to the base of the sand mantle. Charcoal fragments found at the same levels revealed dates which fell within the same periods as those already obtained for analogous industries from Kinshasa and Lunda. A fair typological and chronological correlation could thus be noted between the industries of the southern Zaïre river basin (Table 1). It must, however, be emphasised that at Gombe, just as at Kinshasa and Lunda, the dated samples exhibited no other relation with the archaeological material than to have been found at the same depth as some characteristic artefacts.

However, a systematic study of the reassembly of the worked stones of Gombe (that is, joining together the tools, flakes, core and fragments struck off from the same block) has shown that fitting artefacts were found at several different depths from which different radiocarbon dates have been obtained (the vertical distance between joining pieces sometimes exceeds 1 m). Hundreds of analogous observations have been made through the whole thickness of the sand mantle.

Fitting artefacts are part of the same technological process (blades removed from a blade core for instance) and are strictly contemporaneous. In most cases, the vertical distribution of the elements of the reconstructed cores does not follow the order in which they have been struck off (Fig. 1). This excludes the hypothesis of a later reutilisation of older artefacts. The abundance of reassembled pieces also precludes important lateral transport. Finally we were led to the hypothesis that only subsurface movements of the worked stones could explain this important vertical dispersion of contemporaneous artefacts. On the evidence of the reassembly, it becomes clear that, contrary to appearances, the site of Gombe Point has been disturbed in some way and that the lithic assemblages discovered there at a given depth are not homogeneous. As the Gombe Point can be considered as one of the most complete and most representative prehistoric sites of the southern Zaïre basin, it was thought important to investigate more deeply these disturbances.

Fig. 1 *a* Reassembled blade core from Gombe Point and *b*, vertical distribution of its elements. Numbers indicate the order in which the flakes have been removed: 1a and 1b are fragments of the first flake, 7 is the core itself.



Experimental research

By means of experiments[9], the possibility of subsurface movements[10–11] and of a dispersion of artefacts was tested out. The original materials were used for the experiments. The texture and some mechanical properties of the sediment are given in Table 2.

We investigated whether artefacts, laid down on and/or buried in the sediment could undergo vertical movements, when the sediment is wetted and dried alternatively. Down to depths of 60 cm sand columns were used. Greater depths were simulated by putting down weights on the sediment column. The different methods of wetting and drying were

Table 2 Characteristics of the sediment used in the experiments

Sand content (> 63 μm)[2]	58.1%	
Silt content (2–63 μm)	28.0%	
Clay content (< 2 μm)	13.9%	
Median size	77 μm	
Modal size	95 μm	
Calibrage	very bad	
Liquid limit water content	23%	
Plastic limit water content	12%	
Plasticity index	11%	
Specific weight	2.63 g cm^{-3}	
Angle of internal friction	45°	water content: < 1%
Cohesion	0 g cm^{-2}	
Apparent angle of internal friction	15°	water content: between 20% and 23%
Apparent cohesion	50 g cm^{-2}	
Compressibility constant:		
dry	25.9	slow test
wet (19% water content)	25.6	
Permeability: 10^{-3} cm h^{-1} for a dry volume weight of 1.42 g cm^{-3}		

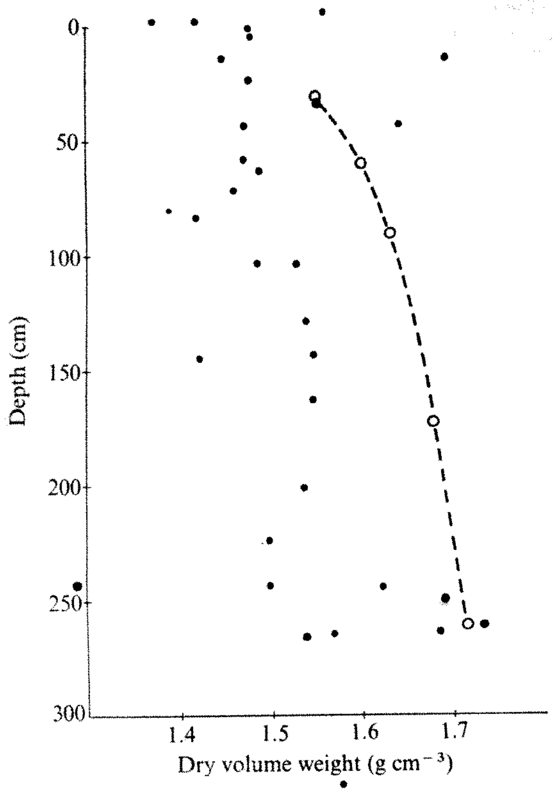


Fig. 2 The dry volume weight of undisturbed soil samples taken from trench 2 at Gombe (●) and the dry volume weight derived from the experiments and the oedometer-test (dotted line). In establishing the latter, a supposed dry volume weight of 1.5 g cm^{-3} of the column above each point was accepted. Therefore the dotted line still gives underestimated values.

simulations of an oscillating water table or of the percolation of rain water from the surface. Three conclusions were reached:

(1) Artefacts laid down on the surface can penetrate into the sediment over a distance of some mm to more than 1 cm, depending on their weight and shape. The amount of penetration shows a linear relation with the logarithm of the number of wetting–drying cycles applied. The explanation lies in a slight compression of the sediment just beneath the artefact. The experiment showed that the weight of the artefacts becomes unimportant and negligible, once they are covered by some cm of sediment.

(2) Buried at greater depths, artefacts do not move vertically, except if the artificial soil column is not entirely consolidated. Artefacts, laid down in an unconsolidated sediment at real or simulated depths of 30, 60, 90 and more than 200 cm, displayed, during consolidation, a general tendency to accompany the descent of the level at which they were buried. Some of them did however descend considerably more or less than the sediment which originally surrounded them.

(3) The dry volume weight of the sediment, measured in the basal part of the different experimental boxes after each experiment, exceeds systematically that of undisturbed samples, taken in the field at depths obtained or simulated in the laboratory (Fig. 2). An oedometer test confirmed the dry volume weight values obtained from the experiments.

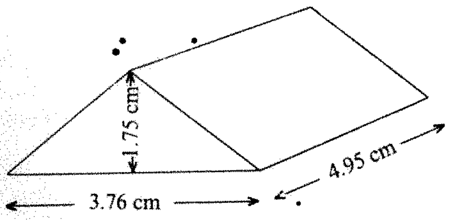
The observation in the field of termite activity and the fact that undisturbed soil samples displayed in several cases a high density of very small (ø about 0.5 mm) biogenic galleries led to the conclusion that the sediment mantle at Gombe is still unconsolidated. It undergoes a double post-sedimentary process: the soil fauna brings up particles to the surface. The dry volume weight of the sediment will diminish along collapsing biogenic structures. A continuous biogenic action and subsequent collapse of the structures

Table 3 Movement indices as measured in the shearing box of a shearing apparatus

Block number	Sediment	Orientation of block	Number of attempts	Mean movement index
1	wet	point up	6	1.16±0.12
	wet	point down	10	0.89±0.21
	dry	point up	5	1.51±0.21
	dry	point down	5	1.28±0.21
2	wet	point up	5	0.95±0.14
	wet	point down	5	0.97±0.15
	dry	point up	5	1.25±0.16
	dry	point down	5	1.38±0.17
3	wet	point up	5	1.18±0.05
	wet	point down	5	0.98±0.08
	dry	point up	5	1.37±0.24
	dry	point down	5	1.28±0.20

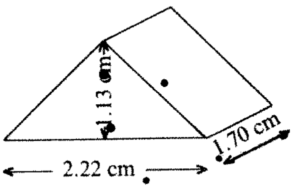
The movement index $i = (\Delta h_0)/(\Delta h_s)$, where Δh_0 is the absolute amount of descent of the gravity centre of the object during exertion of vertical stress on the soil column; Δh_s is the absolute decrease in height of the part of the soil column situated before the measurement between the bottom of the box and gravity centre of the object. For $i < 1$ the object penetrates in sediment situated originally above. In relative terms, the object rises. For $i > 1$ the object penetrates in sediments situated originally below. In relative terms, the object descends.

Block 1



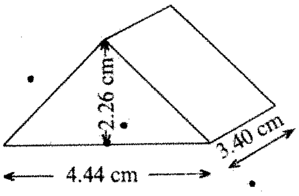
Centre of gravity 1.24 cm below top

Block 2



Centre of gravity 0.80 cm below top

Block 3



Centre of gravity 1.60 cm below top

created in this way, must finally lead to a reconsolidation of the soil column. In fact, the sediment mantle at Gombe must be considered as consolidating permanently in reaction to the continuous biogenic upworking.

In this perspective, conclusion (2) (see above) becomes very significant and was therefore elaborated on by further experiments, simulating the consolidation of the sands by applying vertical stresses. Measurements were made in the shearing box of a monoaxial shearing apparatus: it was noted on several occasions that undeformable objects did not, under compression, strictly accompany the vertical movement of the enclosing sediment. Depending on dimension, form and orientation of the objects and on the water content of the sediment, the objects penetrated into sediments originally situated above or below them. Table 3 gives the vertical movement indices for three wooden blocks.

It should be pointed out that the variability in shapes and dimensions of a lithic industry is obviously considerably higher than that of three wooden blocks. Therefore, the range of vertical movement indices within a whole industry will be also much wider than for the three blocks. Moreover, the experiments are based on the theoretical conception of a homogeneously spread biogenic activity. This is not the real situation in nature. Preferential reworking can contribute to a much higher dispersion than expected on the base of the experiments. Finally, these experiments yield information only about dispersion during consolidation. It is clear that the biogenic activity itself can also create vertical displacement of artefacts.

Discussion

At Gombe, the reassembly shows that strictly contemporaneous artefacts are scattered irregularly over the whole thickness of the homogeneous sand mantle. The experiments confirm the possibility of a postsedimentary differential descent of artefacts in the soil column. This process is catalysed by biogenic activity.

The following facts strongly suggest that this process of redistribution has a general and systematic character in the entire area covered by Kalahari-type sands in Central Africa:

(1) The sites on which our present knowledge of the Prehistory of Central Africa relies are located in the same environmental background—the southern Zaïre river basin.

(2) In these sites, the artefacts are generally distributed in a similar way—"isolated and at no consistent level"[8]—within a homogeneous mantle of redistributed Kalahari sands.

(3) At Lunda, Kinshasa and Gombe, typologically identical assemblages of worked stones are dated within exactly the same periods.

(4) Although systematic reassembly of lithic material has only been carried out for Gombe, similar examples of joining pieces found at different depths have also been observed at Dinga (Kwango) and at Kamoa (Shaba)[12], thus proving that Gombe is not an isolated case.

The most evident result of this redistribution process is a mixing up of originally superposed occupation layers and in most cases the inability to decide if one or more industries are present. The post-Acheulian industries that have been defined in Central Africa probably represent nothing more than heterogeneous assemblages of stone artefacts, without any stratigraphical, typological, chronological or ethnographical significance. The radiocarbon dates give only the age of various charcoal and wood samples but have no direct relation with the archaeological material.

The redistribution process also presents an interest for Quaternary stratigraphical interpretations in the area considered here. Part of the basal concentration of artefacts at Gombe cannot be interpreted as a residual pavement. The contemporaneity of several pieces of this concentration and of some artefacts scattered in the overlying sand mantle can only be explained by a differential descending velocity: artefacts with higher movement indices have already got down to the bed-rock, while others are still descending. The distribution of coarse elements in many stone-line profiles in Central Africa resembles that of the artefacts at Gombe. Many of these stone-lines could perhaps be considered as the result of descent through the overlying mantle[10-11], instead of a residuum, concentrated during an erosion phase. This has implications for the palaeoclimatological interpretation.

Defective interfering particles with covalently linked [±]RNA induce interferon

Philip I. Marcus & Margaret J. Sekellick

Microbiology Section, U-44, University of Connecticut, Storrs, Connecticut 06268

Defective interfering (DI) particles of vesicular stomatitis virus which contain covalently linked complementary [+]message and [−]anti-message RNA as a single-stranded ribonucleoprotein complex within the particle, are extremely efficient inducers of interferon. A single particle can induce a quantum yield of interferon. A single molecule of double-stranded RNA presumed to form, at least in part, on entry into the cell is thought to induce interferon synthesis. Conventional [−]RNA DI particles with the same polypeptide composition as [±]RNA DI particles fail to induce interferon.

LAZZARINI *et al.*[1] have described a defective interfering (DI) particle of vesicular stomatitis virus (VSV), DI-011, which contains covalently linked complementary [+] message and [−] anti-message (genomic) RNA. The [±] RNA exists within the particle as a single strand of 8×10^5 daltons in a ribonucleoprotein complex 0.85 μm long, and on deproteinisation 80–90% of the RNA self-anneals into a double-stranded (hairpin) structure 0.33 μm long[1].

The availability of pure populations of these defective interfering particles which contain RNA capable of assuming a double-stranded configuration and which can specifically bind to and enter cells, provides a unique system for delivering a

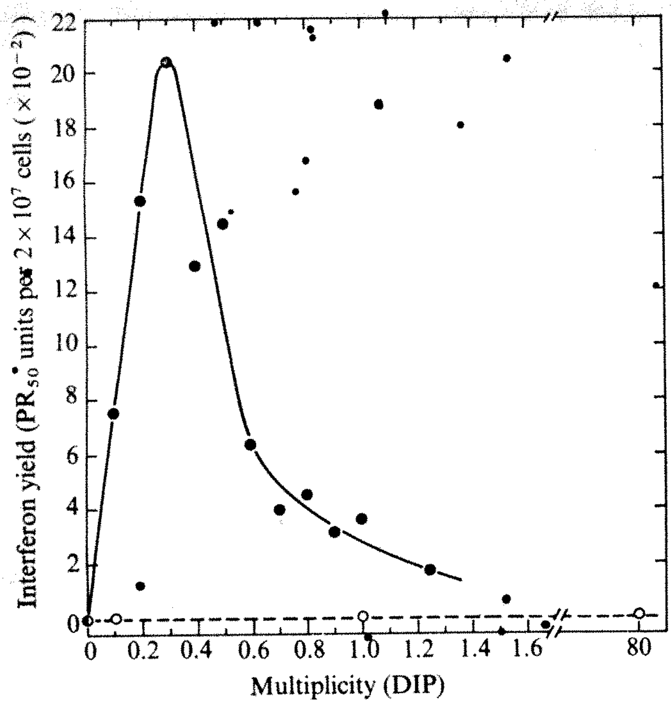

Fig. 1 Interferon inducing capacity of [±]RNA DI-011 (●) and [−]RNA DI-HR (○) particles. Primary chick embryo cells aged *in vitro* for 6 d (ref. 6) were infected with varying multiplicities of DI particles obtained as thrice gradient-purified stocks. DEAE-dextran at 10 μg ml^{-1} was present during virus attachment. Following virus attachment at 37.5 °C for 30 min cell monolayers were washed three times with warm medium and incubated at 40.5 °C with 3 ml of attachment solution[28] per 60-mm dish. After 24 h the supernatant fluid was collected and assayed for interferon as described previously[15]. Activity was recorded as a 50% VSV plaque reduction unit (PR$_{50}$ unit ml^{-1})[15]. Interferon yield is reported as the total amount of interferon released into the medium from a monolayer of 2×10^7 cells in 24 h. This period sufficed to produce maximal yields of interferon over the entire range of multiplicities tested. DI particle titres were determined by measuring the reduction in yield of thrice gradient-purified homologous VSV-HR B particles[8,9].

single molecule of [±] stranded RNA to the cell in conditions which preclude RNA replication[2]. We have used this system to determine whether the [±] RNA of DI-011 particles might assume in the cell a configuration of biological significance beyond that of its role as a DI particle. We examined the function of DI-011 as a defective cell-killing particle[3,4] in conditions where conventional [−] strand RNA particles do not kill cells[3], and tested their capacity to induce interferon production[5,6]. We present evidence here that DI-011 particles do not kill cells, even at multiplicities of infection up to 50, but that a single particle, presumably because of its potential to form double-stranded (ds) RNA and the capacity of dsRNAs to induce interferon[5,7], suffices to induce a quantum yield of interferon, making it the most efficient inducer of interferon discovered so far.

Interferon induction by DI-011

Primary chick embryo cell monolayers aged *in vitro* for 6 d (ref. 6) were challenged with various multiplicities of DI-011 particles (m_{DIP}), on the basis of interfering particle activity[8,9]. Our basic observation is illustrated in Fig. 1 as a dose (m_{DIP})–response (interferon yield) curve and demonstrates that preparations of DI-011 particles contain highly efficient interferon inducers. These data, typical of seven experiments, reveal that initially, increasing the multiplicity of DI-011 particles produced a sharp increase in the yield of interferon, with peak titres (at 24 h) obtained at about $m_{DIP} = 0.3$. (This value ranged from $m_{DIP} = 0.1$ to 1 in seven experiments.) Further increases in m_{DIP} resulted in a marked reduction in interferon yield. The magnitude of the changes in interferon yield observed on increasing the dose of DI-011 particles in the low multiplicity range seemed characteristic of dose–response curves where one particle elicits a quantal response but two or more do not. Consequently, we compared experimentally derived dose–response curves with those expected from a Poissonian distribution of DI particles for cases where quantal yields of interferon would derive from classes (subpopulations) of cells attaching r particles at different multiplicities, m, and values of r (ref. 10). In Fig. 2 we compare the expected curve from the Poisson distribution for the class of cells infected by only one particle ($r = 1$) with the observed data from two experiments. The multiplicity of DI-011 particles which produced the maximum yield of interferon was determined by the least squares method for a best fit curve, with the logarithm of the interferon yield used to minimise the percentage error in the assays for high and low values of interferon. Curves representing other values of r ($r = 2$, $r > 1$, $r > 2$) are not shown, but revealed marked deviation from the observed results. From the goodness of fit of the observed dose–response curve to that expected from the class of cells infected with only one particle of DI-011 ($r = 1$), we conclude that infection with a single particle of DI-011 suffices to induce a quantum yield of interferon—in effect, defining an 'interferon-inducing (IF) particle'. An equivalency between interferon-inducing particles and physical particles is implicit in Lazzarini's observation that

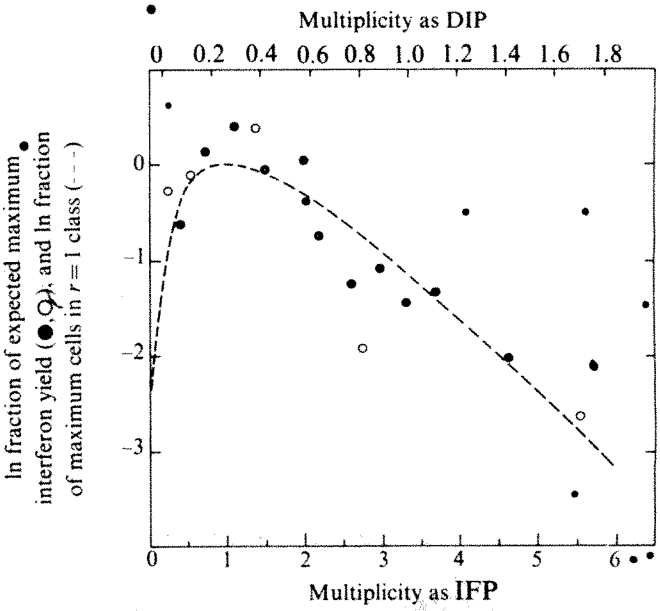

Fig. 2 Comparison of the observed dose (multiplicity)–response (interferon yield) data with those expected if only cells which received one particle were full yielders of interferon—representing the $r = 1$ class of the Poisson distribution where

$$P_{(r)} = (e^{-m}\,m^r)/r!$$

In this case, m is the multiplicity of DI-011 particles, and $P_{(r)}$ the fraction of cells infected by r particles of DI-011. The class of cells which is infected by a single particle (that is, the case where $r = 1$) is $P_{(1)} = me^{-m}$ (ref. 10). ●, ○, Data from Fig. 1 and one additional experiment. - - - -, Curve derived from the $r = 1$ class of the Poisson distribution. The upper abscissa shows the multiplicity of infection based on the DI particle titre whereas the lower abscissa defines the DI-011 stock in terms of the number of interferon-inducing (IF) particles. On the ordinate, the 'expected' maximum interferon yield was based on a maximum derived from a least squares fit of the experimental points. For these experiments, the ratio IFP:DIP ≃ 4, and indicates that more virions can function as interferon inducers than as DI particles. In this regard, Lazzarini consistently finds at least a threefold excess of physical particles, as assayed by electron microscopy, to DI particles, as measured by the interference test[8,9] (personal communication). Allowing for this factor of three, the multiplicity on the top and bottom abscissae become almost the same, indicating an equivalency of physical and IF particles.

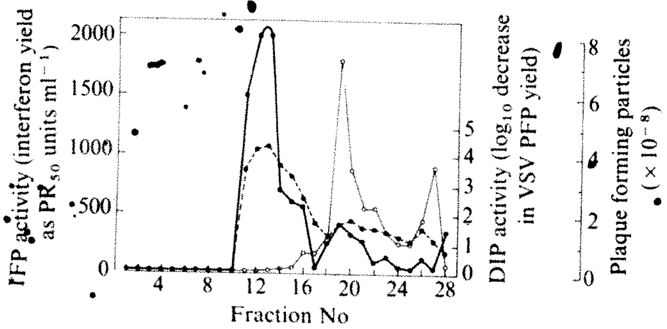

Fig. 3 VSV-MS(DI-011) profiles of plaque-forming particle (○—○), defective-interfering particle (● - - - ●) and interferon-inducing particle (●—●) activity following velocity sedimentation on a linear sucrose gradient. A partially purified preparation of VSV-MS(DI-011) labelled with ^{3}H-uridine and containing roughly equivalent amounts of B and T particles (kindly supplied by R. A. Lazzarini) was applied to a 17 ml 5–40% linear sucrose gradient and centrifuged at 75,000*g* for 120 min at 4 °C. Fractions were collected from the top of the gradient and analysed for TCA-precipitable radioactivity (data not shown), plaque-forming particle, defective-interfering particle and interferon-inducing particle activity as described elsewhere[3]. Assays of interferon inducing activity for each fraction were carried out at optimal multiplicities for interferon induction (Fig. 1).

there is about a threefold excess of physical particles to defective-interfering particles in purified preparations of DI-011 (R. A. Lazzarini, personal communication). The data also indicate that cells which attach two or more DI-011 particles yield little or no interferon. Factors affecting the production (synthesis and release) of interferon and an antiviral state in this multiplicity range will be reported elsewhere.

Conventional [—] RNA particles representing a common one-third length component from the Indiana HR strain of VSV did not induce interferon when tested similarly (Fig. 1).

Comparison of different types of particle

A stock containing DI-011 and standard infectious B particles was obtained from BHK-21 cells in conditions which produced roughly equivalent amounts of DI and B particles. These particles were concentrated by centrifugation, and profiles of interferon-inducing, defective-interfering and plaque-forming particle activity established by testing each fraction of the gradient for these respective activities as described previously[3] (Fig. 3). These results demonstrate that the interferon-inducing and defective-interfering particle activity profiles are essentially coincident throughout the gradient, with both activities peaking at fractions 12 and 13. Infectivity in the form of plaque-forming particles peaks at fraction 19. We conclude that the interferon-inducing particle activity of DI-011 particle preparations corresponds in sedimentation characteristics to those of defective-interfering particles.

Prevention of interferon induction

Inhibitors of cellular RNA and protein synthesis, such as actinomycin D and cycloheximide respectively, prevent interferon induction[5]. Table 1 demonstrates that when either of these drugs is present together with an optimal multiplicity of DI-011 interferon-inducing particles, little or no interferon is produced. Thus, it seems that new cellular mRNA and protein synthesis are required for the production of interferon which follows infection with DI-011 particles.

When preparations of DI-011 particles are exposed to antiserum specific for the Indiana serotype of VSV, there is a marked reduction in the capacity of that preparation to induce interferon (Table 1). We conclude that the molecule(s) responsible for interferon induction in populations of DI-011 particles gain entry into the cell through particles which can be specifically neutralised with VSV antiserum.

Effects of heat or ultraviolet radiation

Stocks of gradient-purified DI-011 particles were exposed to different doses of ultraviolet or heated for 20 min at 50 °C and tested for their capacity to induce interferon. Table 1 shows that heated DI-011 particles remained fully functional as interferon inducers. The same heat treatment when applied to complete virions reduced infectivity, cell-killing particle activity, and virion-derived transcription 100-fold[4]. Figure 4 shows that the interferon-inducing capacity of DI-011 particles is extremely resistant to inactivation by ultraviolet. A dose of ultraviolet (2,615 erg mm^{-2}) equivalent to 50 and 10 lethal hits to plaque-forming and cell-killing particle activity, respectively[4], had virtually no effect on interferon induction by DI-011 particles, but reduced the interfering capacity of DI-011 particles 10-fold or more (data not shown).

Induction of antiviral state in different cell types

Some cell systems seem to acquire an antiviral state on stimulation with interferon inducers even though little or no interferon may be detected[11,12]. Consequently, we tested for intracellular viral interference in cells in which the yield of interferon induced by DI-011 particles was abundant (primary chick embryo cells)[3], low (human FS-4 cells)[13] or nil (GMK-Vero cells)[14]. Monolayers of these three cell types were challenged with various multiplicities of DI-011 particles. After incubation for 20 h, the supernatant fluid was removed and assayed for its interferon content[15]. To establish the degree of intracellular viral interference, the cell monolayers were challenged with Sindbis virus ($m_{PFP} = 5$) in the presence of actinomycin D (1 μg ml^{-1}). The data in Table 2 reveal that DI-011 particles induce an heterologous antiviral state capable of reducing the yield of challenge Sindbis virus in chick embryo cells by 1,000-fold or more—even at the multiplicities of inducer particles which produce relatively low yields of interferon ($m_{IFP} > 2$). However, we note that the yield of interferon at these multiplicities, although low compared with the titres obtained at $m_{IFP} = 1$, is nonetheless significant ($\simeq$ 100 units ml^{-1}) and could itself account for development of an antiviral state during the 20-h test period. This consideration does not hold for human FS-4 cells, since little or no interferon was detected over the 100-fold range of multiplicities tested and illustrated in Table 2. Thus, DI-011 particles in human FS-4 cells produced an antiviral state in the apparent absence of released interferon. The heterologous antiviral effect (challenge with Sindbis virus) which develops in these human cells on infection with DI-011 particles indicates that the yield of interferon from cells is but one measure of DI-011 particle

Table 1 Factors affecting the induction of interferon by ±RNA DI-011 particles

Treatment of [±]RNA DI-011	Interferon yield (PR_{50} units per 2×10^7 cells)
Untreated (control)	37,000
Actinomycin D (1 μg ml^{-1})	25
Cycloheximide (50 μg ml^{-1})	< 20
VSV antiserum*	< 20
Heat (50 °C for 20 min)	33,000
Ultraviolet†	39,000

In all experiments an optimal multiplicity of DI-011 particles, that is, $m_{IFP} = 1$, was used to achieve maximal interferon yield as measured 24 h after infection. Actinomycin D or cycloheximide were added to the medium immediately after DI particle attachment and remained throughout the 24-h test period. The antiserum used during virus attachment could reduce the plaque-forming particle titre of a VSV Ind. stock by 99.9% in 30 min. The heat treatment reduced cell-killing, plaque-forming (and virion-transcription) activity each by 99% (ref. 4).

*Treatment with normal rabbit serum at a comparable dilution produced control (untreated) values of interferon.

†Figure 4 illustrates the exact relationship between ultraviolet dose and interferon induction by DI-011 particles, and compares it with the surviving activity for infectivity (plaque formation).

Table 2 Induction of intracellular interference against Sindbis virus by [±]RNA DI-011 particles in different cell types

Multiplicity (DI-011)	Sindbis virus yield (PFP ml^{-1}) Primary chick embryo cells	Human FS-4 cells	GMK-Vero cells
0	6.2×10^9	6.4×10^9	9.4×10^9
0.1	1.9×10^6	1.2×10^{10}	4.1×10^9
1	4.9×10^5	3.4×10^9	1.2×10^{10}
10	4.4×10^6	1.2×10^8	1.2×10^{10}
100	9.0×10^5	3.6×10^6	4.8×10^9

Monolayers of cells were infected with varying multiplicities of once gradient-purified [±]RNA DI-011 particles. Virus attachment was carried out for 30 min at 37.5 °C in attachment solution[28] containing 10 µg ml^{-1} DEAE–dextran. Monolayers were washed three times with warm medium and incubated at 40.5 °C (chick cells) or 37.5 °C (FS-4 or GMK-Vero cells) with 3 ml of medium per 60-mm dish. After 24 h, supernatant fluids were collected, processed, and assayed for interferon as described previously[15]. These monolayers were washed twice with attachment solution and infected with wild-type Sindbis virus at m_{PFP} = 5–10. Actinomycin D (1 µg ml^{-1} for chick cells and 10 µg ml^{-1} for FS-4 and GMK-Vero cells) was included during virus attachment to prevent any further induction of interferon[6]. Cells were washed four times to remove unattached virus and 3 ml of medium was added to each plate. Infected monolayers were incubated at 37.5 °C for 10 h and the supernatant fluid titred by plaque assay for the Sindbis virus yield.

action on the cell; another is development of an intracellular antiviral state[11].

However, we have not ruled out the possibility that very small amounts of interferon are being produced[12], nor have we determined whether the reduced efficiency of inducing an antiviral state reflects a lowered probability of attaining a double-stranded configuration of [±] DI-011 RNA in FS-4 cells. The results with GMK-Vero cells are clear—no interferon is produced, nor is an antiviral state achieved by DI-011 particles in this cell which seems genotypically incapable of responding to inducers of interferon[14].

Effect of [−]RNA defective interfering particles

Some standard preparations of DI particles might consist of both [−] and [±] (also [+]?) type particles, and although [−]DI particles do not induce interferon (Fig. 1), they might interfere with, or enhance, the interferon-inducing capacity of [±]RNA particles. We tested this possibility by simultaneously infecting primary chick embryo cells with a multiplicity of DI-011 optimal for interferon induction (m_{IFP} = 1) and a high multiplicity of a conventional [−]DI-HR particle (m_{DIP} = 50). These large numbers of [−]RNA DI particles reduced the interferon-inducing capacity of DI-011 more than 10-fold, even though this multiplicity of [−]DI-HR particles had no adverse effect on the cells as judged by examination under phase contrast optics, or by counting single cells by the window technique[16]—confirming earlier observations that these particles are not intrinsically toxic[3,8,9,17]. We are continuing to study this effect.

[±]RNA DI-011 particles are not intrinsically toxic

Because a single non-infectious particle of VSV—a defective cell-killing particle—suffices to kill a cell[3], it is important to use highly purified populations of DI particles to test for their intrinsic toxity[3,8,9,17]. Preparations of [±]RNA DI-011 particles gradient-purified three times did not affect the plating efficiency of single GMK-Vero or chick embryo cells as tested up to m_{DIP} = 50, and so behaved like conventional [−]RNA DI particles[3]. Multiplicities in excess of 50 [±]RNA DI particles resulted in a measurable decrease in plating efficiency and the appearance of a cytopathic effect in monolayer cultures. It is not clear whether these effects reflect a cumulative toxic effect of these particles or the presence of otherwise non-detectable levels of infectious cell-killing particles. We suspect the latter, since inclusion of VSV antiserum in the medium shortly after infection prevents the progressive cytopathic effect observed in monolayer cultures infected at m_{DIP} > 50.

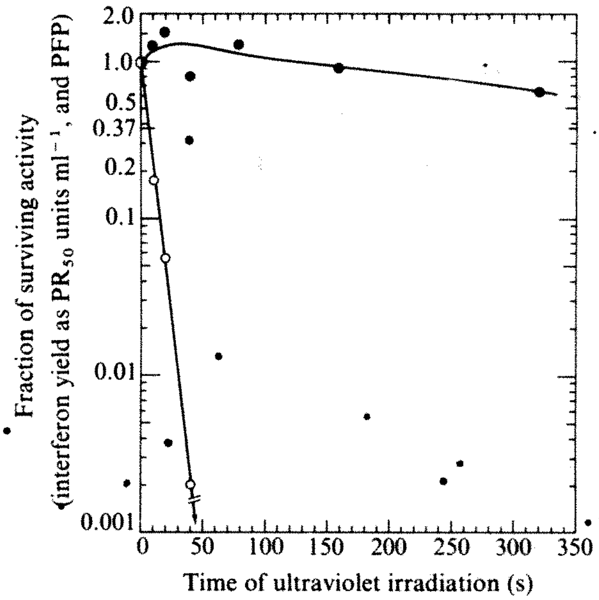
Single particle of [±]RNA DI-011 induces interferon

Our data indicate that a single [±]RNA DI-011 particle suffices to induce a quantum yield of interferon, and does not kill cells. The dose (multiplicity)–response (interferon yield) curve generated by DI-011 particles fits best a model where cells infected with a single particle (the $r = 1$ class of the Poisson distribution)[10] synthesise and release a full yield of interferon, thus identifying a new attribute of these subvirions—their capacity to act as discrete interferon-inducing (IF) particles. The dose–response curve also indicates that cells infected with two or more IF particles respond differently and yield little or no interferon.

Requirement for dsRNA

We infer that interferon induction results from the action of a helical structure formed from some, if not all, of the complementary bases which make up the covalently linked [+] message–[−]anti-message single-stranded RNA of the infecting DI-011 particle. In the same conditions, single DI-HR particles of conventional [−]RNA composition do not induce interferon. Thus, at an average of about 0.3 DI particle per cell, [±]DI-011 and [−]DI-HR induce the synthesis of approximately 25,000 and < 10 PR_{50} (VSV) units of interferon respectively per 2×10^7 aged chick embryo cells[6]. That a double-stranded RNA formed intracellularly is the putative inducer of interferon in cells infected with DI-011 can also be inferred from the fact that [±]DI-011 and [−]DI-HR particles both obtain polypeptides from viral transcripts synthesised by the coinfecting standard B particle of VSV[18]. R. Lazzarini has shown by double isotopic labelling and coelectrophoresis that the polypeptide composition of DI-011 is identical with that of the parental infectious type (personal communication). DI-011

Fig. 4 Interferon-inducing capacity of ultraviolet-irradiated DI-011 particles. Comparison with plaque-forming particle activity. One-half millilitre of thrice gradient-purified DI-011 particles and of wild-type VSV Ind. (strain MS) infectious B particles were added to separate 100-mm Petri dishes and exposed to a germicidal lamp (2,735 Å) which delivered 65.4 erg mm^{-2} per 10 s. Samples of irradiated particles were tested either for interferon-inducing capacity (IFP, ●) as in Fig. 1, or for plaque-forming activity (PFP, ○).



and DI-HR particles apparently share identical polypeptides therefore, differing only in their content of covalently linked [+]message–[−]anti-message, and [−]anti-message RNA, respectively. In addition, neutralisation of the interferon-inducing capacity of DI-011 preparations with specific antiserum to VSV (Indiana) demonstrates that the inducer molecule gains entry into the cell in a particle which possesses the specificity of the Indiana serotype, as do these DI-011 particles.

It will be difficult to prove directly the existence of a helical structure of [±]RNA at the level of the one molecule per cell presumed to form on interaction of a cell with a single particle of DI-011, particularly if once inside the cell, the number of base-pairs required for inducer function is as few as the six to twelve reported necessary for poly(rI)·poly(rC) to function similarly[19]. We do not know how the inducer molecule assumes a functional configuration in the cell, but it seems likely that in aged chick embryo cells (and perhaps to a lesser extent in human FS-4 cells) sufficient viral nucleoprotein is removed from the viral ribonucleoprotein core to permit a threshold amount of base pairing. Conceivably, only the [+] stranded moiety of the [±]RNA functions as inducer. The high yield of interferon produced on infection with only a single DI-011 particle, presumably one molecule of [±]RNA, makes it, on a molar basis, and in terms of a delivery system, the most efficient inducer of interferon so far discovered.

The fact that the interferon-inducing capacity of the DI-011 particle is not affected by heat and ultraviolet is consistent with the [±]RNA's being the molecule responsible for interferon induction[20]. We do not know yet whether a given molecule of [±]RNA from DI-011 can serve both as a template for replication, as in homotypic interference, and an inducer of interferon.

Possible role of [±]RNA particles in virus infection and disease

The remarkable efficiency of the [±]RNA DI-011 particle in inducing interferon and/or an antiviral state, coupled with the fact that interferon-mediated interference can prevent cell killing by VSV[15,21], suggests that the [±]RNA class of DI particle might play a part in persistent infection and viral disease beyond that presently postulated for its conventional [−]RNA counterpart[2]. Involvement of the interferon system in persistent infection would provide a mechanism whereby cells can survive in the presence of lethal virus—an aspect not satisfactorily accounted for by present models. Thus, although a single DI particle can prevent completely the replication of its standard infectious helper virus[3,8,9], it does not prevent cell killing by that coinfecting virus[3]. Furthermore, we have demonstrated that single cells infected with an otherwise lethal dose of VSV, survive and form normal-sized colonies if, before infection, they have acquired an interferon-mediated antiviral state[15]. Current experiments provide evidence of a role for [±]RNA DI particles in persistent infection. They demonstrate that pretreatment of mouse L cells with [±]RNA DI-011 particles renders them refractory to cell killing by wild-type VSV, a property not shown by [−]RNA DI-HR particles in the same conditions (M.J.S. and P.I.M., in preparation). We also note that the only DI particles of several types tested by Holland and Villarreal[17] which are found consistently to establish persistent infection in BHK cells coinfected with VSV, were those derived from stocks of *ts*-mutant G31(III). We have tested a preparation of long DI particles prepared from this mutant as supplied by E. Reichmann (obtained from J. Holland), and found that it acted as an excellent interferon inducer (data not shown). We also note that the presence, or generation of [±]RNA DI particles might account for the induction of interferon in mice by VSV[22], or rabies virus (refs 23, 24 and references contained therein). We are now examining different types of DI particle for their IF particle activity, and by implication, for the presence of [±]RNA containing particles.

Characterisation of a closely related [±]RNA DI particle of VSV corroborates the existence of this new class of defective interfering particle[25]. The ease with which single molecules of DI-011 [±]RNA can be delivered to the cell, and their efficiency at inducing interferon synthesis and/or an antiviral state makes them new and potent tools to define and understand the many effects of dsRNA on cells[7,26,27].

This research was aided partly by the Damon Runyon-Walter Winchell Cancer Fund, the National Science Foundation and National Cancer Institute, and benefited from the use of the Cell Culture Facility supported by the National Cancer Institute. We thank Drs L. Andrew Ball and Robert C. Warrington for their critical review of the manuscript.

Note added in proof: We have observed that the sparing of cells from the lethal action of VSV (and Newcastle disease or Sindbis virus) which develops upon pretreatment with DI–011 particles is obliterated completely when antiserum to interferon is present during the pretreatment. These results provide further evidence that the antiviral state induced by the DI–011 particle to heterologous viruses is interferon mediated.

letters to nature

Q0000−398 is a high-redshift quasar with a large angular size

REDSHIFTS of between 2.5 and 3.1 have been measured for nine optically-selected quasars as part of the Cerro Tololo survey of the Southern Hemisphere (M. G. Smith, see ref. 1). None of these quasars were known to be radio sources. We chose several accessible quasars from Smith's list as a starting point in our investigation to see if they might not be radio sources. We report that Q0000−398 is a quasar of high redshift and large angular size.

During October, 1976, we detected two of the quasars using the three-element interferometer of the National Radio Astronomy Observatory (NRAO), Green Bank, West Virginia,

Table 1 Data on quasars of considerable angular extent

*In Table 1 of Baldwin *et al.*[6] the optical and radio positions are reversed.

with a 300–1,200–1,500-m baseline configuration, operating at 2,695 MHz. The radio map for Q0000−398 (18 mag, z = 2.827) shows two weak components separated by 134±40 arc s. If these components are associated with the optical object, Q0000−398 is the quasar with the largest known angular size at its redshift value. (Inspection of the Whiteoak extension print of this area of sky shows no galaxies in this area, which may be emitting this radiation.)

The second quasar investigated, Q0049−393 (18 mag, z = 2.94) was also detected (S_{2695} = 26 mJy, where 1 mJy = 10^{-29} W m^{-2} Hz^{-1}), but was unresolved.

These two quasars were observed along with several other

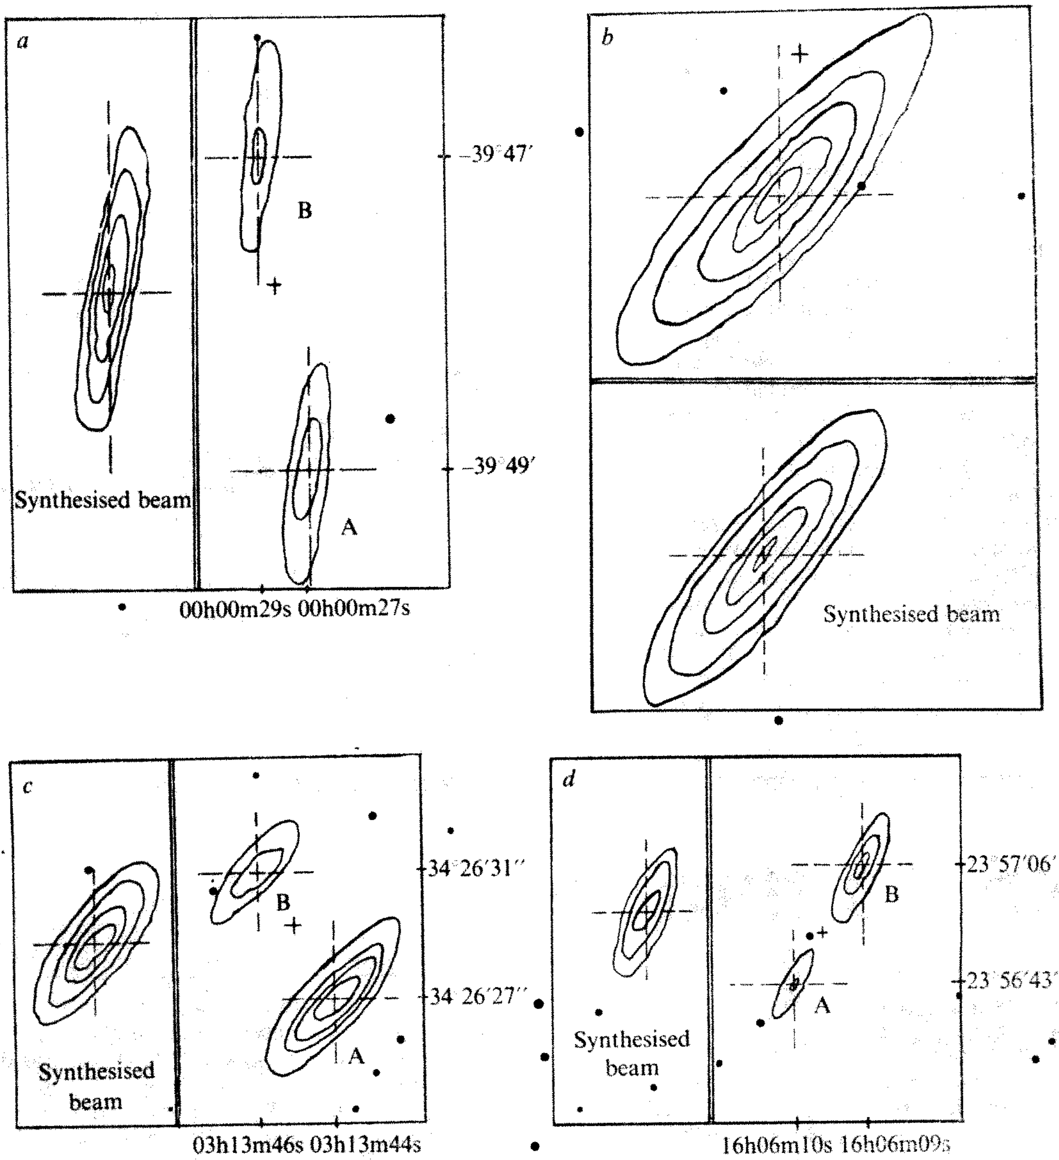

Fig. 1 Radio contour maps with synthesised beams at 2695 MHz for *a*, Q0000−398; *b*, M0758+120; *c*, OE323 and *d*, OS210. Crosses represent optical centroids. The angular separation of the radio and optical centroids for M0758+120 is about 14 arc s.

steep-spectrum quasars listed in Table 1. All of the sources were observed in ideal weather conditions with good hour angle coverage in the *u–v* plane (allowing for the constraints of the elevation angle limit at low declinations, roughly ±3h at −39°). Details regarding the operation and characteristics of the interferometer are given in ref. 2.

Results for the quasars found to have considerable angular extent are presented in Table 1. Figures 1 *a–d* present clean maps at 2,695 MHz of four of the sources studied: Q0000−398, OE323, M0758+120, and OS210. Synthesised beams accompany each map. The radio component associated with M0758+120 is shifted by about 14 arc s from the optical counterpart. Further studies are required to determine if a fainter, weaker radio component is present, or if the radio source is actually associated with the quasar.

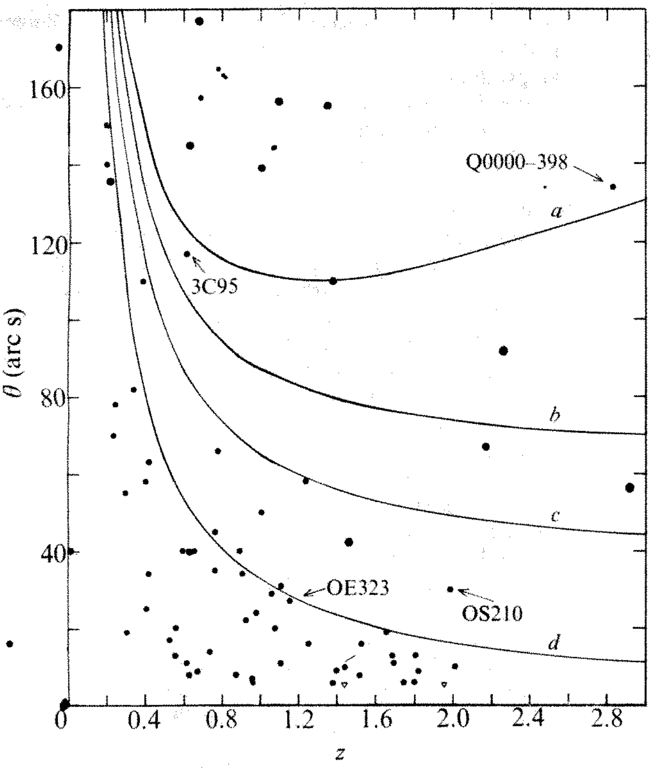

Fig. 2 Angular size–redshift diagram for 55 quasars with spectral indices $\alpha(408\text{–}1{,}415\,\mathrm{MHz}) \geq 0.80$ and $\alpha(1{,}415\text{–}5{,}000\,\mathrm{MHz}) > 0.60$. Curves *a–d* demonstrate the behaviour of a standard rod of 950 kpc in Einstein–de Sitter, Milne, de Sitter (steady state) and static Euclidean universes, respectively. Triangles represent upper limits. A Hubble constant of $H_0 = 50\,\mathrm{km\,s^{-1}\,Mpc^{-1}}$ is assumed.

Assuming that quasar redshifts are cosmological, Friedmann models predict that quasars with constant linear dimensions will exhibit a minimum angular size as a function of redshift. The Einstein–de Sitter model, for example, with deceleration parameter, $q_0 = 1/2$, predicts a minimum near $z = 1.2$. Wardle and Miley[3] have found that the maximum angular size of a sample of 166 quasars decreases with increasing redshift much faster than predicted by any conventional cosmological model. They conclude that evolutionary effects are responsible for the apparent Euclidean behaviour of the upper envelope to the angular size redshift diagram. The large angular extent of Q0000−398, however, tends to weaken this conclusion and suggests that a minimum may exist in the upper envelope function (see Fig. 2).

Additional evidence that the angular dimensions of quasars may exhibit a minimum is indicated by the results of Hewish *et al.*[4]. Their study of the angular sizes of compact components of strongly scintillating 3CR sources shows evidence of the mean angular sizes increasing with higher redshift, as one would expect in evolving cosmological models with q_0 in the range of 0.5 to 2.0. Readhead and Hewish[5] conclude that the apparent deficiency of small-diameter compact sources at large redshifts is real and significant.

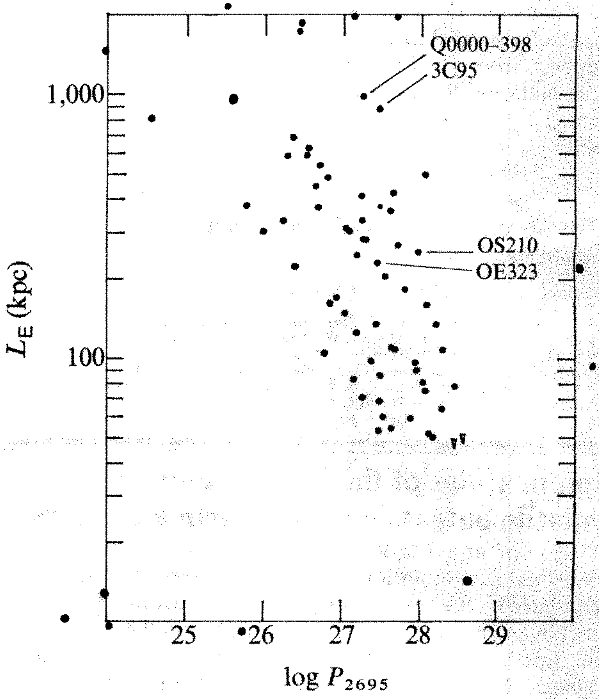

Fig. 3 Linear separation L_E (kpc) against 2,695 MHz spectral power (W Hz^{-1}) for Einstein–de Sitter model. Data are for the quasars in Fig. 2. Triangles represent upper limits.

Although Wardle and Miley[3] find no evidence for radio selection effects as a result of the sample being selected by flux density, since Q0000–398 was selected optically and has a much lower flux density than most of the quasars in their sample, this suggests that radio selection effects may be important. A radio selection effect can arise from samples being selected by flux density if the luminosity of quasars decreases with increasing separation of components.

The largest angular-size quasars tend to have much steeper spectra than found for small-diameter quasars. Using the spectral-index criteria that $\alpha(408\text{–}1{,}415\ \mathrm{MHz}) \geq 0.80$ and $\alpha(1{,}415\text{–}5{,}000\ \mathrm{MHz}) > 0.60$ (where $S \propto \nu^{-\alpha}$) eliminates most small-diameter quasars as well as those with low-frequency cutoffs from the Wardle–Miley diagram. The remaining subset of 52 quasars, along with the other new data presented in this paper, is shown in Fig. 2. Figure 3 shows the relation between radio luminosity at 2,695 MHz and linear size for the quasars in Fig. 2. An Einstein–de Sitter model and a Hubble constant of $50\,\mathrm{km\,s^{-1}\,Mpc^{-1}}$ has been assumed. The subset of 50 quasars shows an apparent inverse correlation (coefficient = −0.63, significant at the 0.01 level) between luminosity and linear size (2 quasars with upper limit angular sizes were not included). No correlation between luminosity and linear size has been found for quasars having either spectral index flatter than the criteria set above. These quasars are more likely to possess self-absorbed components, which may smear out any relation between luminosity and linear size.

The results reported here demonstrate the importance of considering radio selection effects in the angular diameter–redshift diagram. Since any radio selection effects are removed when quasars are selected optically, more extensive mapping programs should be undertaken, looking specifically for large-scale structure around optically-selected, high-*z*, quasars.

Implications of the Viking results for volatile outgassing from Earth and Mars

TUREKIAN and Clark[1] have recently discussed an inhomogeneous accumulation model for terrestrial planets, have compared the outgassing product from a veneer of carbonaceous chondrites with the abundances of volatiles on Earth and predicted the amounts of various gases for Venus. The recent measurements of rare gas abundances on Mars by Viking[2–4] have prompted us to test such a model for Mars. We find that not only the relative abundance of H, C, N, ^{20}Ne, ^{36}A, Kr and Xe but their total amounts can be best explained if the outer layers of Earth and Mars were made of material similar to ordinary chondrites (LL) as suggested by Anders[5], rather than carbonaceous chondrites as assumed by a number of authors in recent years.

In a non-homogeneous accretion model[1,5,6] the planet is supposed to have accumulated from at least two different types of material. The accretion starts in a relatively hot solar nebula and therefore the inner part of the planet contains mostly high temperature condensates such as metallic iron, magnesium silicates, Ca–Al–Ti and rich oxides. As the planet grows, it is heated by the release of gravitational energy and if it is large enough (compare Earth and Venus) the proto planet becomes completely molten and liquid iron and nickel sink to the centre. With the passage of time both the proto planet and the solar nebula cool and the growing planet can then acquire a layer of low temperature condensates containing relatively large amounts of volatiles such as carbon, water, nitrogen and the rare gases. If the upper layers could then get heated again either by the radioactive decay of ^{40}K, ^{238}U and ^{232}Th or by some other mechanism, the volatiles contained in the low temperature condensates can be released to the surface of the planet. The suggestion is that this process was responsible for the formation of the atmosphere and oceans of the Earth.

Table 1 Volatiles on Earth, CCl and ordinary chondrites (g cm^2) and atom ratios normalised to carbon

	H	C	N	^{20}Ne	^{36}A	^{84}Kr	^{132}Xe
Atmosphere, hydrosphere, crust, upper mantle (*a*)*	35,800	52,800	1955	1.3×10^{-2}	4.1×10^{-2}	2.0×10^{-3}	1.2×10^{-3}
Carbonaceous chondrites (Cl) (*b*)†	34,300	(52,800)	4990	3.5×10^{-4}	2×10^{-3}	5.9×10^{-5}	7.6×10^{-5}
Ordinary chondrites (LL) (*c*)‡	24,200	(52,800)	3010	5.3×10^{-3}	3.6×10^{-2}	5.2×10^{-4}	6.4×10^{-4}

‡Data from ref. 15.

Accepting this model in principle, we wish to discuss the nature of condensates which can most reasonably explain the volatile inventory on the surface of Earth and Mars.

Table 1 shows the total abundances of six volatile elements present in the Earth's atmosphere, hydrosphere, crust and upper mantle, adopted from Turekian and Clark[1]. The second line shows the abundances of these elements if they represent outgassing from carbonaceous chondrites (also from Turekian and Clark). Here we normalise the abundances for carbon. (Assuming 3.5% concentration by weight in the carbonaceous chondrites, complete outgassing from a 4-km layer of CCl would correspond to the abundance of carbon on Earth). Line 3 which represents the ratio of Earth to CCl shows that the agreement is far from satisfactory for the case of rare gases. Disparities of up to a factor of 37 exists for the case of ^{20}Ne.

A similar treatment using the volatile content of ordinary chondrites (LL) rather than CCl, produces a more satisfactory result. Line 4 is the total abundances of volatiles outgassed from a layer of ordinary chondrites, again normalised for carbon. Because of relatively low abundance of carbon (0.12%) in ordinary chondrites, line 4 represents outgassing products from a layer 116 km thick. The ratios shown in line 5 indicate a much better overall agreement for ordinary chondrites than for CCl (line 3).

Table 2 shows a similar treatment for Mars. Here of course there are more unknowns than on Earth, especially for C, N and H which may be in the surface layers rather than the atmosphere. We therefore follow a slightly different approach in constructing the table. Line 1 shows the abundances of rare gases, carbon and nitrogen measured in the atmosphere. Line 2 shows the amounts which would be expected if the outgassing is from the ordinary chondrite type material and normalised for ^{36}A. Line 3 then shows the amount of volatiles which may be in the surface layers of Mars or have escaped the planet.

The agreement for Kr and Xe is reasonably good. This leads us to presume that such an approach to the deduction of the total outgassing on Mars may be valid. If so, a number of inferences can be drawn from Table 2 as follows.

(1) The total volatile inventory on Mars corresponds to complete outgassing from an 0.5-km layer of ordinary chondrites or, if the layer is ~100 km thick (compare Earth), the outgassing has been only 0.5% effective.

(2) 145 g cm^{-2} of C corresponds to ~500 g cm^{-2} of CO_2. As only a very small amount of CO_2 is in the atmosphere, relatively large amounts (>90%) may be in the regolith, as proposed earlier by Huguenin[7].

(3) 8 g cm^{-2} of nitrogen either lies buried in the surface or has escaped the planet[8].

(4) 66 g cm^{-2} of H corresponds to ~600 g cm^{-2} of H_2O. Although the hydrogen content of the ordinary chondrite is the most poorly known piece of data in Table 2, it is interesting to note that the recent Viking results provide two interesting pieces of data which are relevant in this case. First, the surface layers of Mars seem to contain ~1% H_2O (ref. 9). If we assume that the regolith is ~100 m thick this would correspond to ~200 g cm^{-2} of H_2O in the Martian surface. The second Viking observation relevant here is that the residual polar cap in the nothern hemisphere is made of water ice[10]. Although there are large uncertainties in the estimates of ice thickness in the polar cap, our inventory of water outgassing on Mars would

Table 2 Martian volatile inventory derived by degassing from ordinary chondrites (g cm^{-2})

	H	C	N	^{20}Ne	^{36}A	^{84}Kr	^{132}Xe
Mars atmosphere observed	—	5.0	0.50	$< 10^{-4}$	1.0×10^{-4}	$\sim 6 \times 10^{-6}$	$\sim 1 \times 10^{-6}$
Ordinary chondrite (LL)	66	145	8.3	10^{-5}	1.0×10^{-4}	2×10^{-6}	$\sim 3 \times 10^{-6}$
Volatiles escaped or on surface	66	140	7.8	–	–	–	–

allow a thickness of up to 40 m, if escape of water from Mars can be ignored. If not[11], the polar cap thickness would be accordingly smaller.

(5) Major volatiles deduced from Table 2, H_2O, CO_2, N_2, add up to ~1,100 g cm^{-2}. It has been suggested[12] that Mars goes through major climatic fluctuations and at times all volatiles could be in the atmosphere. According to our inventory the total mass of the atmosphere in such a case would be ~1,100 g cm^{-2} which, for Martian gravity, corresponds to ~400 mbar; an atmosphere composed of ~50% CO_2 and ~50% H_2O with traces of nitrogen.

The ^{40}A degassing problem is a very different question than that of general outgassing of the planet (such as CO_2, H_2O, rare gases and N_2). ^{40}A is a radiogenic product of ^{40}K and was nearly completely absent in the earlier stage of planetary formation (its degassing should be a function of its production and could be continuing at the present time (compare the Moon))[13].

Viking measurements showed an ^{40}A/^{36}A ratio in the Martian atmosphere 10 times greater than the ratio in the Earth's atmosphere[2]. Soil sample analyses[14] give an upper limit for the potassium concentration at the surface of 0.25% (compared with the potassium concentration of 1.6% (ref. 1) in the Earth's crust).

We calculated the necessary thickness of a layer to account for the observed quantity of ^{40}Ar in the Martian atmosphere assuming two different values for the potassium concentration: 0.25% which is upper limit from Viking experiments and 0.08% which is the concentration in ordinary chondrites (LL). We find that layers of 2.5 km and 8 km respectively can account for the results of Viking measurements. These thicknesses are to be compared to the half-kilometre thickness calculated by us previously to account for the other volatiles (Table 2). This difference implies a different mechanism for outgassing of ^{40}A compared with the rest of Martian atmosphere.

The fact that the absolute amount of ^{40}A in the atmosphere of Mars could be explained by ~10 times less K in the upper layers of Mars than on the Earth, is interesting. It implies that the upper layers of Mars have not been substantially enriched in K and other radioactive elements perhaps because of the absence of extensive melting in the interior of Mars during its formation.

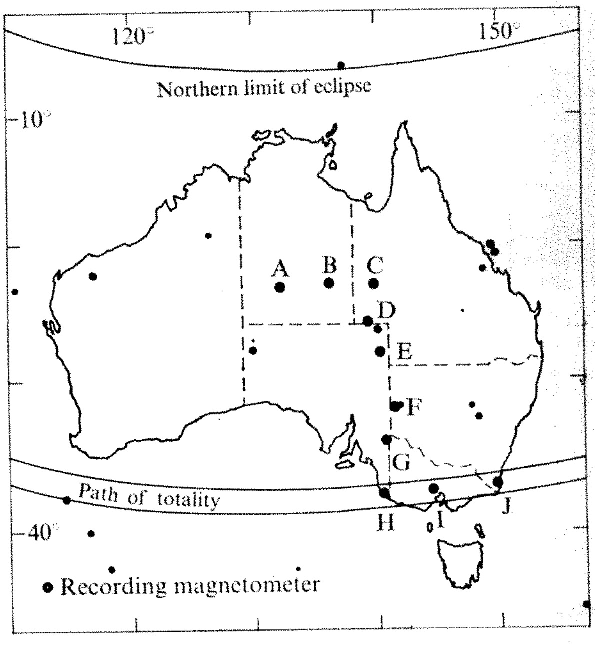
Magnetic observations of the solar eclipse of 23 October 1976 in Australia

SOLAR eclipses may cause geomagnetic effects by disturbing the flow of electric currents in the ionosphere[1,2], and a number of observations of this phenomenon have been made in recent years[3,4]. To monitor any magnetic effects of the eclipse of 23 October 1976, we operated recording magnetometers at 10 sites in central and eastern Australia (Fig. 1); these instruments were in addition to the regular observatories of the Bureau of Mineral Resources near Perth and Melbourne. We present here a preliminary analysis of the declination variations recorded in the path of totality at stations H (Millicent, S.A.) and J (Merimbula, N.S.W.).

The recording instruments were Gough-Reitzel variometers[5], set to take readings at intervals of 10 s. Because any eclipse effect was expected, on elementary grounds, to be mainly in the declination component, the declination sensors of the instruments were increased in sensitivity by a factor of four above their normal level. Timing of the 10-s readings (on film) was estimated to be accurate to within a few seconds.

The day of 23 October 1976 proved to be magnetically quiet in the declination component. Minor activity occurred at 0711 h Universal Time (UT), about 30 min after eclipse totality had passed. The declination records for stations H and J have been digitised at 10-s intervals for a 4-h period centred on the eclipse, normalised by calibration factors, and are shown plotted in Fig. 2.

Fig. 1 Sites of recording magnetometers operated to monitor the 23 October 1976 eclipse. Site H is Millicent Airfield (lat. 37°35′S, long. 140°22′E). Site J is Merimbula Airfield (lat. 36°55′S, long. 149°53′E).

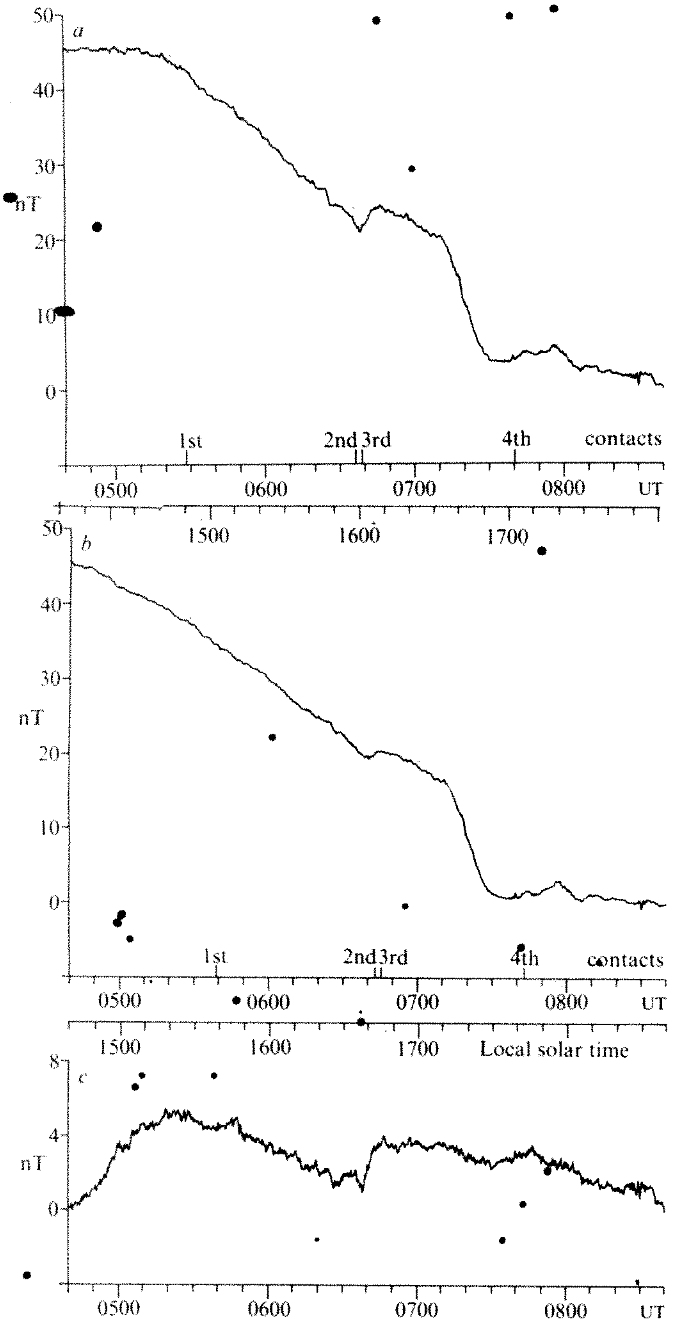


Also shown in Fig. 2 is the difference between them, subtracting trace J from trace H.

Natural electromagnetic induction in south-east Australia has been well studied by two previous magnetometer array experiments[6,7], which showed the coast effect to be strong in the vertical component of magnetic fluctuations, but to be negligible in the declination component. Thus, stations H and J were placed at opposite coastlines to achieve the greatest time difference between them for the passage of eclipse totality. The previous array studies have also shown that magnetic substorms and similar events occur near-simultaneously across the area, but that the quiet daily variation moves across with local solar time.

Thus, in Figs 2*a* and 2*b* one may expect to see: a background quiet daily variation, with station H lagging behind station J by 38 min; possibly some substorm activity occurring simultaneously at H and J; and an eclipse signal moving rapidly from H to J. In Fig. 2*c*, where the traces are subtracted, the effect of the substorm activity should disappear to first order, and one may expect to see the daily variation subtracted from itself 38 min out of phase to give a smooth curve of amplitude approximately 5 nT, and some interference effect between the eclipse signals at H and J. It is significant that the activity starting at 0711 UT has indeed largely cancelled itself out in Fig. 2*c*.

Fig. 2 *a*, The declination record for site H. *b*, The declination record for site J. *c*, H-record minus J-record. All records are plotted relative to arbitrary zeros. Amplitude conversion factors are 6.4 nT per minute of arc for station H, and 6.8 nT per minute of arc for station J.



The signal causing a depression in the declination traces at about 0638 UT is of interest as a possible eclipse effect, because: (1) it occurs at the time of the eclipse; (2) it does not cancel itself out in Fig. 2*c* as does the activity of 0711 UT; to be so strongly non-uniform it must be of local origin; and (3) it is of the correct sign, and order of magnitude, to be expected for the effect of an eclipse[2]. Several aspects inconsistent with a simple eclipse model should be pointed out, however: (1) the signal at 0638 UT is not of the same strength at stations H and J; (2) it has not moved from west to east at the known rate of the centre of eclipse totality on the ground; and (3) it starts gradually but ends abruptly.

Digitisation of the records obtained at the other stations will be undertaken and a more comprehensive report is planned.

We thank J. Styles for assistance with the field-work, and M. N. Sloane for assistance with the data reduction.

Magnetic superleaks

Two new natural materials which behave as superleaks to superfluid ^{4}He and also have magnetic properties are described here. In the search for magnetic superleaks the first choice was, obviously, a highly magnetic material such as a manufactured ferrite which has the advantage that its porosity is very uniform. We tested such a material but apparently not at a low enough temperature to be able to detect any onset point for the superfluid ^{4}He. The pores or gap distances must be extremely small[1]. Second, natural magnetic materials, among which the most obvious were different types of the so-called magnetites, were tested. Two magnetites of apparently quite different origin have been tested with superfluid ^{4}He. One from the south-east of Argentina, Province of Rio Negro about 41° S latitude and about 30 km from the Atlantic Ocean (sample A) and another of unknown origin taken at random from the Mining Department of the University of Delft (sample B). An X-ray diffraction analysis of these two samples gave the following components: For sample A, haematite (Fe_2O_3) (ferromagnetic), magnetite (Fe_3O_4) (ferrimagnetic), mica and garnet [$(Mg,Fe)_3Al_2(SiO_4)_3$] (paramagnetic) and for sample B, mainly magnetite (Fe_3O_4) (ferrimagnetic) and chlorite, a sheet silicate [$(Mg,Fe)_5AlSi_3O_{10}$]$(OH)_8$ (paramagnetic). Both samples are anisotropic aggregates and the magnetic characteristics are given at room temperature.

The method already described[2] to determine the onset temperatures of superleaks was used. A carbon sensor as a detector of the superfluid rests on the surface of a flat superleak inside a cell. When the superfluid through the superleak finally reaches the sensor, a noticeable jump in its resistance value is noted. This method has the advantage over the capillary method that no direct observations of the liquid helium level are necessary, difficulties inherent in an optical cryostat.

The obtained onset temperatures are: for sample A 1.57 K and for sample B 1.72 K. Applying the well-known expressions[3] of Ginzburg and Pitaevskii and of Mamaladze, the values for the gap width were obtained, respectively: for sample A, 36 Å and 24 Å and for sample B, 42 Å and 29 Å. Note that for superleaks made of natural materials the values of the onset temperatures are only approximate since they vary from different samples of the same material because of the non-uniformity of the diameters of the pores or gap widths. Also, with these measurements, there is a real doubt that the superleak is really a superleak. For instance, the way in which the superleak is fixed to the system, whether it is soldered to the glass of a cell or fixed with an indium wire gasket, might present microscopic leaks. Also it is impossible to apply any kind of reliable leak detection to a superleak. It is, however, possible to overcome that doubt with a reasonable number of observations and, as far as possible, mounting and dismounting the same sample to observe the reproducibility of the measurements.

The search for magnetic superleaks had its origin in the anisotropic magnetic superfluid phases of liquid ^{3}He recently found. The application of magnetic superleaks to the peculiar anisotropic magnetic superfluid phases of liquid ^{3}He at very low temperatures[4,5] might be relevant. However, to check magnetic superleaks in the anisotropic superfluid phases of ^{3}He will not be easy. In that physical situation those phases would be influenced by an adequately magnetised finite geometry medium, not necessarily those described here, which they filled, since below the transition temperatures the liquid has the properties of a superfluid and has magnetic properties, compared with those of nematic liquid crystals.

I thank Dr A. J. Leggett for valuable and encouraging remarks about the potential implications of a magnetic superleak in the superfluid phases of ^{3}He. Thanks are given to Dr R. A. Kühnel for the X-ray diffraction analysis and to Mr J. G. Krom for helping with the measurements.

Towards a theory of stochastic vorticity-augmentation

THE mechanism of genesis of atmospheric tornado-like vortices is not yet known, although the hydrodynamic mechanism of a mature tornado is reasonably well understood thanks to recent research efforts. This lack of understanding of the physics of tornado genesis has been a great handicap in attempts to avert tornado occurrences. I present here a new hypothesis to account for the formation of tornadoes.

The hypothesis is based on the observation that thunderstorm associated tornadoes almost invariably occur in the environment of an intensely (vertically) sheared horizontal wind, say $V_x(z)$ which is penetrated by a vertical columnar jet-draught along the z-axis. It is easily recognised that the vertically sheared wind field could serve as an abundant source of ambient vorticity; nonetheless a casual theoretical consideration[1] of such a wind-jet interaction does not lead to a net gain of axial vorticity (ω_z) for the vertical jet at the expense of the horizontal vorticity ($\omega_y = -\partial V_x/\partial z$) according to the Helmholtz vorticity transport equation:

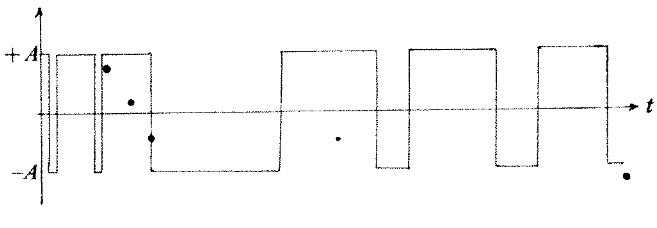
$$\frac{d\omega_z}{dt} = \omega_x \frac{\partial V_z}{\partial x} + \omega_y \frac{\partial V_z}{\partial y} + \omega_z \frac{\partial V_z}{\partial z} \simeq \omega_y \frac{\partial V_z}{\partial y} \qquad (1)$$

assuming $\partial/\partial z \ll \partial/\partial y$. A closer examination of the present wind-jet interaction, taking into account the resulting random lateral deflections of the jet caused by the alternating vortex sheddings in the wake of the cross-wind over the jet[2,3], shows that random sharp velocity gradients ($\partial V_z/\partial y$) are induced at the boundary of the random impulsively oscillating jet. This random input ($\omega_y \partial V_z/\partial y$) in equation (1) converts the latter into a stochastic differential equation having the axial vorticity (ω_z) as the output function. It is this stochastic vorticity transfer process that is considered herein as primarily responsible for starting a columnar vortex leading eventually to a mature tornado vortex after the pendant funnel extending down from the cloud base to the ground.

In this present study of the wind-jet interaction, I have constructed an extremely simplified model with only bare essential physics. For instance the entrainment which accounts for the incorporation of the ambient air into the jet is not taken into account. The hydrodynamic problem here is the determination of the probable increments of the jet axial vorticity due to the induced random input ($\omega_y \partial V_z/\partial y$) as a consequence of the random lateral displacement of the jet which can be viewed as a beam in Brownian motion[4]. Recognising the filamentary structure in a vortex jet[5] and even in the fine scales of turbulent flows[6], we envisage the jet as a bundle of vortex filaments along the jet axis (z) which faces a vertically sheared horizontal wind along the x-axis thus shedding alternating vortices on each side and, in so doing, inducing alternating hydrodynamic Magnus forces (along y-axis) on the jet. It can be shown that this many-filament system constitutes essentially a system of coupled nonlinear oscillators[3], under the influence of a high-frequency harmonic forces, which therefore oscillates as though a random force were acting on it[7,8]. The present many-body system is subdivided into a subsystem, namely a filament, and its environment. The influence of the environment on the subsystem is treated in a way similar that of a heat bath of statistical mechanics except that instead of a random force[9] we have random vorticity impulse with stochastic properties supposedly given. In this way the equation governing the growth of axial vorticity for the total system is reduced to that for the subsystem alone with the quantity ω_z in equation (1) representing an unnormalised axial vorticity at a sample point (o) of the test filament; the quantity $(\omega_y \partial V_z/\partial y)_o$ an effective random vorticity impulses at the point o. We have thus a one-dimensional model neglecting the feedback and damping of the vortex-jet disturbances.

Consider a surface velocity gradient $(\partial V_z/\partial y)_o$ depicted by the simplest plausible stationary function known as the random telegraphic signals with values $+A$ and $-A$ alternately as shown in Fig. 1 where $A\alpha(t) = \omega_y(\partial V_z/\partial y)_o$ and $|\alpha(t)| = 1$. The probability of switching over the signal from one value to its

Fig. 1 Sample function of the $(+A, -A)$ random telegraph signal $(A\alpha(t), t > 0)$



opposite is assumed to be governed by a Poisson distribution at a mean rate of $\mu\ s^{-1}$.

The incremental axial vorticity can be obtained from equation (1):

$$\Delta\omega_z(\tau) = \omega_z(\tau) - \omega_z(0) = A\int_0^\tau \alpha(t)\,dt \qquad (2)$$

The ensemble average of the squared incremental axial vorticity is given by[10]

$$\langle[\Delta\omega_z(\tau)]^2\rangle = A^2\tau \int_{-\infty}^{\infty}\langle\alpha(o)\alpha(s)\rangle\,ds \qquad (3)$$

the integrand $\langle\alpha(o)\alpha(s)\rangle$ denotes the correlation function of the stationary random function $\alpha(t)$ and is equal to $\exp(-2\mu|s|)$. Thus:

$$\langle[\Delta\omega_z(\tau)]^2\rangle = \omega_y{}^2(\partial V_z/\partial y)_0^2\tau\,\mu^{-1} \qquad (4)$$

which gives the important parameter depicting the stochastic growth rate of the columnar axial vorticity of a vortex filament of the jet.

The more detailed probabilistic information is given by the probability $P(\Delta\omega_z, t)d(\Delta\omega_z)$ that the increment $\Delta\omega_z$ at time t lies between $\Delta\omega_z$ and $\Delta\omega_z + d(\Delta\omega_z)$. Recognising the Markovian nature of the stochastic process herein, we can determine the probability density $P(\Delta\omega_z, t)$ by solving its governing equation in the form of a driftless Fokker-Planck equation for diffusion[9] and obtain the Gaussian distribution:

$$P(\Delta\omega_z, t) = (4\pi Dt)^{-1/2}\exp[-(\Delta\omega_z)^2/4Dt] \qquad (5)$$

where $D = \langle(\Delta\omega_z)^2\rangle/2\tau$. If a critical value for $\Delta\omega_z$ is prescribed, say $(\Delta\omega_z)^* = \beta\sqrt{\langle(\Delta\omega_z)^2\rangle}$, for large β,

$$P[\Delta\omega_z > (\Delta\omega_z)^*] \simeq (2\pi)^{-1/2}\beta^{-1}\exp(-\beta^2/2) \qquad (6)$$

In conclusion, a new cause of vorticity transfer between an ambient sheared-wind and a transverse-penetrating jet is proposed for which an elementary one-dimensional theory is formulated. It points out the relevant quantities to be determined, theoretically or experimentally, in describing the present stochastic mode of vorticity-augmentation.

Theoretical evidence for metastable cyclic ozone

OZONE is a vital component of the atmosphere. Knowledge of its properties is important to the understanding of its involvement in chemical and photo-induced reactions which can affect the stability of the ozone concentration in the upper atmosphere. The reactivity of ozone and its unusually low thermochemical stability with respect to partial dissociation are difficult to reconcile with an apparently multiply bonded symmetric bent structure. This has led to speculation[1,2] concerning alternative forms of ozone such as the equilateral triangular cyclic form (isoelectronic with cyclopropane) from which facile partial dissociation could be envisioned. To have an important role such a form would presumably need to be thermally accessible from the ground state and bound with respect to partial dissociation. The spectroscopic structure determination of the symmetric bent ground state[3–10] has been finalised[10] (r_e (O–O) 127.1 pm, angle 116.8°), and there was recently experimental confirmation[11,12] of excited states of this species[13–16,22] which are bound with respect to dissociation, including the predicted $^3B_2$ state[13–17,22]. Investigations of bound excited states which are stable to partial dissociation have been stimulated by the sequential observation during O_2 radiolysis experiments[12,18,19] of two short-lived 'ozone precursors' $O_3{}^\alpha$ and $O_3{}^\beta$ following recombination of ground state O_2 and O. $O_3{}^\beta$ may be vibrationally excited ground state ozone[20], whereas the $O_3{}^\alpha$ precursor which shows absorption[12] at ~ 315 nm in the ultraviolet (and possibly[21] the emission observed at $1500\ cm^{-1}$ in the infrared) has not yet been given an identity beyond an apparent lifetime of 5 µs. The species showing the single infrared emission[21] is interesting as D_{3h} cyclic ozone is expected to show one (degenerate) infrared active fundamental, fewer than any alternative structure. Theoretical evidence for the stability of cyclic ozone has been conflicting. In 1973 Wright[1] calculated it to be 26 kJ mol^{-1} more stable than the ground state; in 1972 and 1975 Hay *et al.*[13,[illegible]2] calculated it to be less stable by ~ 150 kJ mol^{-1} (that is, above partial dissociation energy $\Delta H^\circ = 101$ kJ mol^{-1}) and in 1974 Shih *et al.*[14] have concluded it is 63 kJ mol^{-1} above the ground state. Shih *et al.*[14] have recognised that considerable uncertainty still exists in their computation on total and relative energies, and their calculated ground state structural parameters differ significantly from experiment. We have reinvestigated the relative stability of cyclic ozone and symmetric bent ozone and have obtained a total energy for the ground state of −224.7710 hartree which is 471 kJ mol^{-1} lower than the previous best model wavefunction of Hay *et al.*[13] who predicted cyclic ozone to be above dissociation. In other words, the relative shortcoming in total energy in all previous computations on each conformer has been around five times the key energy difference between ground state ozone and the partial dissociation products, $\Delta H^\circ = 101$ kJ mol^{-1}. The computed optimum geometric parameters (bond length $r_e = 126.4$ pm and bond angle $\alpha_e = 117.3°$) are sufficiently close to the experimental values to lend some confidence to our model wavefunctions in regard to structural predictions. The corresponding wavefunction for cyclic ozone has an energy expectation of −224.7637 hartree at an optimum bond length of $r_e = 143.5$ pm (bond angle 60°). On this evidence the difference in the energy of the local minima on the ozone ground state conformation hypersurface is less than one fifth of the partial dissociation energy. We, therefore, confidently predict the existence of a bound species of ozone having an equilateral triangle conformation. We believe this species may be the $O_3{}^\alpha$ precursor, which in the experiments referred to[18,19] is presumably vibrationally excited.

Our disagreement with Hay *et al.*[13] regarding the stability of the cyclic conformer has a number of origins. Hay *et al.* seem not to have optimised molecular geometries using their best bases and their best correlated wavefunctions, and have apparently omitted polarisation basis functions in any study of the cyclic conformer. The basis sets we used are comparable to the best previously used at the Hartree Fock level E_{HF} (bent, SCF optimised geometry) −224.314 hartree, E_{HF} (bent, CEPA optimised geometry) −224.3058 hartree and E_{HF} (cyclic, CEPA optimised geometry) −224.3011 hartree. The significantly lower final conformational energies we have obtained despite the fact that our basis is not designed to obtain inner 'atomic' correlation effects is due to the use of a pair natural orbital (PNO) basis which is designed to optimise the configuration expansion convergence. We used ~ 750 PNO configurations in our final calculations on each conformer, which is equivalent to 1–2×10^4 canonical configurations based on HF orbitals.

Our computer modelling of the wavefunction of each ozone species was intended to reduce previous basis set and geometry-optimisation limitations, taking the following course:

(1) Initial optimised geometries for each species were obtained from a survey of the surface (1014 points)[23] using simple independent particle SCF wavefunctions based on atomic STO-3G basis augmented with sets of single component gaussian bond functions between each pair of oxygens (3 sets). The bond function sets comprised one *s* gaussian and three *p* gaussians all of which were single gaussian fits to corresponding Slater functions of exponent $\xi = 1.1$. These bond functions afforded some valence deformation and polarization.

(2) With these geometries, large and flexible atomic oxygen basis {(9*s*, 5*p*) → [5, 1, 1, 1, 1; 3,2] in standard notation; ref. 24} were situated at each nucleus, and three equivalent sets of mid-bond bond functions for each species were optimised at the SCF level by varying the characteristic Slater exponent for the sets (ξ_{opt} (ground state) = 1.87, ξ_{opt} (cyclic) = 1.95).

(3) With the partially optimised set of 45 expansion functions so obtained (data to be published, P.G.B.) for each species, the valence SCF molecular orbitals were subject to a localisation procedure and the many-body effects of electron correlation among the valence electrons was estimated by following the CEPA–PNO procedure of Meyer[25] and Ahlrichs *et al.*[26]. At this stage correlation interaction between pairs only belonging to the same atom as well as the intrapair correlation were taken into account (yielding 57 sets of pair natural orbitals).

(4) Using the incomplete CEPA–PNO wavefunctions, geometric parameters were reoptimised (small changes resulted) yielding the values quoted above.

(5) Full valence CEPA–PNO correlation energy corrections were obtained for each reoptimised geometry species (including 81 sets of pair natural orbitals) yielding the respective energies for the ground state and cyclic ozone quoted above. The CEPA–PNO energy difference of 19.2 kJ mol^{-1} favouring symmetric bent ozone is paralleled by the corresponding PNO–CI[25,26] difference calculated by us of 15.8 kJ mol^{-1}.

We believe that limitations in our model due to incomplete basis sets and neglect of core and core–valence correlation will affect our computations of relative energies by less than 20 kJ mol^{-1}, and that further refinement of the wavefunctions for each species will not affect our prediction of the existence and stability of cyclic ozone.

We expect cyclic ozone to be involved in ozone reaction kinetics and atmosphere chemistry where inclusion of its role may improve atmospheric modelling[27]. In interstellar gas clouds such a metastable species might be expected to be trapped by slow collisional deactivation. The absence of a permanent dipole moment, however, is against the usual methods of detection of pure rotational transitions which would provide the best confirmation of the identity of cyclic ozone.

We are working to calculate the spectroscopic and other properties of cyclic ozone.

High absorption efficiency for ingested plutonium in crabs

ALTHOUGH marine organisms have been strongly implicated in the biogeochemical cycle of plutonium, there is disagreement as to whether they can assimilate it efficiently[1–7]. We have examined the fate of plutonium in a single, worm-crab food chain after ingestion of the isotope which had been metabolically incorporated into the predator's food. Contrary to absorption efficiencies of tenths to hundredths of 1% derived from studies with vertebrates[8–10], our results show that relatively large fractions of plutonium are readily absorbed from ingested food and incorporated into the predator's tissues.

The radioisotope ^{237}Pu was used in all experiments. The advantages of using ^{237}Pu tracer to study environmental kinetics of ^{239,240}Pu have been discussed by others[5,11]. The relatively high specific activity of this isotope facilitates the use of amounts of plutonium similar to the levels found in the environment. Tracer solutions were prepared by adding sufficient ^{237}Pu in either the +4 or +6 oxidation state to 50 ml cotton-filtered seawater to give a concentration of approximately 8 nCi ml^{-1}. Polychaete worms (*Nereis diversicolor*) were exposed to labelled seawater for several days, thoroughly rinsed and whole-body counted for ^{237}Pu activity as described previously[5]. In the first series of experiments six individual shore crabs (*Carcinus maenas*) received two to three contaminated *Nereis* and were whole-body counted immediately, replaced in their individual aquaria with running seawater (≃18 °C) and given sufficient unlabelled worms to ingest throughout the experiment. The crabs were whole-body counted periodically to measure excretion of the radionuclide, and at the same time their faecal pellets were filtered from the water and monitored for ^{237}Pu to assess defaecation as a route of elimination. At prescribed times, individuals were dissected to show the distribution of residual ^{237}Pu. In a second series of experiments, two large edible crabs (*Cancer pagurus*) ingested four separate rations of labelled worms within 48 h and were subsequently maintained for 3 weeks in conditions similar to those already described. The size of *Cancer* prohibited whole-body counting and the elimination was estimated from the knowledge of ^{237}Pu ingested, lost by defaecation and retained in the various tissues.

Figure 1 shows the plutonium whole-body elimination patterns displayed by *Carcinus*. The initial rapid loss noted during the first 2–4 d represented gut clearance of unassimilated plutonium. This was verified by analysis of faecal pellets; during this period approximatety 90% of whole-body loss occurred through defaecation. The fraction of total loss due to defaecation then decreased markedly from 90 to 40%, suggesting the increasing importance of soluable excretion processes. This period corresponded to the phase during which whole-body elimination proceeded at a much slower, nearly exponential rate (solid lines in Fig. 1). This phase represents loss of that fraction of plutonium absorbed from the food; extrapolation of this component to day 0 facilitates estimation of absorption efficiency. The high values for the six individuals, from about 20–60%, were not expected in view of results from previously published vertebrate studies[8–10], and we are unaware of comparable data for invertebrates.

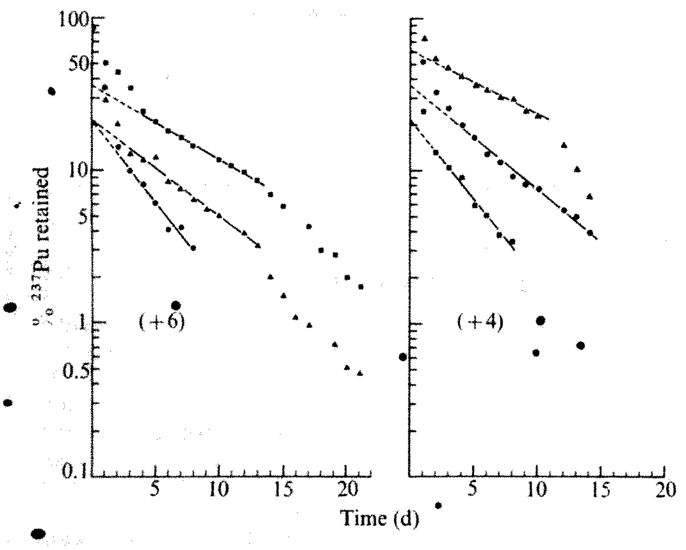

Fig. 1 Elimination of ^{237}Pu after single ingestion of labelled worms by six individual *Carcinus*. Assimilation coefficients for Pu were estimated by resolving the different components of the loss curves using standard mathematical methods routinely used in radioecological studies[12–15]. The loss curves are treated as a two component elimination system described by the expression $A_t = A_0(a_1 e^{-k_1 t} + a_2 e^{-k_2 t})$, where A_t is the whole-body radioactivity at time t, and A_0 is the initial whole-body radioactivity immediately following ingestion of labelled food. a_1 represents the fraction of unassimilated ^{237}Pu eliminated at a rate k_1; a_2 is that fraction of assimilated ^{237}Pu eliminated at rate k_2; a_2 (absorption efficiency in our study) is determined graphically by extrapolation of the linear part of the long component (solid line) to time zero. Enhanced elimination of the assimilated ^{237}Pu noted in three individuals after about 12–14 days is assumed to be a reflection of increased metabolic rate probably associated with a given stage of the intermoult cycle; therefore these data were not included when fitting the longer component by a least squares estimate.

Dissections indicated that the plutonium absorbed from the food had become distributed within the crabs. In most cases the largest fraction (43–85%) was in the hepatopancreas which serves as the digestive gland. Lesser amounts were in other tissues such as shell (8–43%), and in muscle and gill (5–10%). ^{237}Pu was at or below the detection limit in stomach, gut and haemolymph. In the second experiment a larger crab, *Cancer*, was given more ^{237}Pu to facilitate measurement. Because of the experimental design it was not possible to estimate absorption efficiency; however, it was undoubtedly high, for 12 and 41% of ingested +6 and +4 ^{237}Pu, respectively, was retained in the tissues at the time of dissection. The relative distribution of the radionuclide among the tissues of *Cancer* generally confirmed that noted with the shore crabs.

Concentrations (c.p.m. per g wet mass) of residual ^{237}Pu in both crabs were by far the highest in hepatopancreas, with less in gill, stomach, shell and muscle. Certain trace elements[16] and radionuclides[17] are absorbed from ingested food and can accumulate to high levels in crustacean hepatopancreas; similar mechanisms seem to operate in the initial absorption of the large fraction of plutonium removed from the crab's food during passage through the gut. The low concentration of Pu in muscle relative to the other tissues was similar to that found in crabs and lobsters which either had been contaminated in the environment[2,18] or had accumulated the radionuclide directly from water in laboratory studies[19].

Reports[1,7,20] have emphasised the need for more information on transuranic transfer coefficients between various links in marine food chains to predict total amounts potentially available to man. We have examined this aspect in a simple, two-step invertebrate food chain and have found that Pu naturally incorporated into food can be assimilated into the predator's tissues with efficiencies several orders of magnitude higher than those characteristic of mammalian systems. The difference in absorption efficiencies between mammals and marine crustaceans is most likely a result of differences in digestive physiology; it is, however, conceivable that the way the radionuclide was administered influenced the degree of assimilation. Although only data for crabs are reported here, similar experiments carried out in our laboratory suggest that high plutonium absorption efficiency is also common to other marine invertebrates. Thus, it is possible that data indicating extremely low gastrointestinal absorption of plutonium by vertebrates are not applicable to species comprising the bulk of the marine biomass.

When is sex environmentally determined?

THERE are several sex determining mechanisms which produce two sexes in a population (dioecy or gonochorism)[1–5]. In many of these, the offspring's sex is determined at or before conception, as in male or female heterogamety. In several organisms, however, the offspring's sex is determined later than conception, by some environmental influence upon the offspring. We consider here why these environmental mechanisms have been maintained; that is, why have they not been replaced with an alternative system that determines sex at conception? We propose that labile sex determination (not fixed at conception) is favoured by natural selection when an individual's fitness (as a male or female) is strongly influenced by environmental conditions and where the individual has little control over which environment it will experience. Our argument also applies to sex expression in hermaphrodites[6,7].

The basis of a theory of labile sex determination lies with two principles, first noted by Fisher[8], who applied them to sex ratio evolution: (1) both sexes contribute autosomal genes equally to the next generation, that is, everyone has a mother and a father, and (2) the fitness of an individual is measured relative to others of the same sex. Relative fitness is the ratio of an individual's actual fitness (survival × fertility) to the average fitness in that sex and must account for the relative abundances of both sexes. Selection thus favours the ability of a parent or offspring to manipulate the sex ratio to result in offspring with the highest fitness in each sex[9].

To illustrate, if an individual finds itself in an environment where it can become a below average female or an above average male, selection will favour its becoming male because it can pass on more of its genes than if it were female. Selection may therefore favour 'environmental sex determination' (ESD) because of the control it allows an individual. When sex is determined at conception, the individual no longer has this control but can begin 'developing into' its sex immediately. Early development of sex allows an individual to become a better male or female and is probably the major advantage of genotypic sex determination.

Selection should most strongly favour ESD when (1) the offspring enters an environment, away from the parent, which has a large effect on its lifetime fitness; this environment is patchy, some patches conferring more of an advantage to females than to males and vice versa; and (2) the offspring and parent have little control (or predictive ability) over which patch type the offspring enters. These conditions make it unfavourable to determine sex at conception because of the possibility that a male will enter a patch that is much more favourable for a female, or the reverse.

There are several ways in which an environment may be 'patchy' relative to the selective value of being a male or a female. (1) There is local competition for mates. If an area has a high concentration of females and a low concentration of males, then an individual enjoys the greatest success when it is a male. (2) Resources may have differential value to males or females, and they may be patchy in distribution. If an offspring must garnish most of its resources in a restricted environment, and if there is a sex difference in the advantage of the resource, then the offspring should become the sex which benefits the most under the circumstances. Resources which may have differential value to sex function include sunlight (in plants) and other nutrients for growth (a large size is often more advantageous to one sex than the other). (3) Predation (or other mortality sources) may be patchy and could be sex specific.

The inability of the parent or offspring to choose a patch type also has a major role in favouring ESD. If an offspring can choose its patch, sex can be determined at conception and the offspring enters the patch that will give its sex the highest fitness. Inability to choose patch type will often be correlated with immobility; however, parental mobility does not preclude ESD. If parents deposit offspring in (or offspring enter) environments from which they cannot escape during some crucial stage of development, selection may favour an environmental mechanism when the parent or offspring is unable to evaluate the patch type prior to entry. In contrast, if the parent can evaluate the patch (but the offspring cannot leave it), selection may favour parental ability to match the sex of the offspring to the appropriate patch. Such mechanisms occur among parasitic Hymenoptera[10,11].

Environmental sex determination is known in several plants and animals, and these seem to fulfil the expected characteristics.

Many species of nematodes which parasitise insects (family Mermithidae) and some which parasitise plants (genera *Meloidogyne* and *Heterodera*) are believed to have ESD[2,12–14]. The life histories are basically alike: young (eggs) are either deposited on a host or they locate a host and enter. The larvae attain almost adult size while in the host. Adults (at least males) leave and mate outside the host[12,15].

The sex of the nematode is determined after entering the host, and sex ratio varies with parasite density inside the host. High density results in an abundance of males, whereas low density results in mostly females[2,12–14]. Large size is apparently more important to female than to male fitness (females are universally the larger sex in nematodes). Thus a juvenile in a crowded host will not be able to attain a large size; it can become an average male or a below average female: selection should favour it becoming the male. In uncrowded hosts, an individual gains more as a female.

Among marine invertebrates, ESD is known in *Bonellia* (an echiurid), and several parasitic isopods (for example, *Stegophryxus* and *Ione*)[2,3,16]. These organisms usually have dwarf males which live on the female. Larvae are planktonic and adults are immobile (*Bonellia*) or are restricted to the host. Larvae that settle alone become females, those that attach to females become males. In these, the resource of strongest sex-dependent value is the female, because of the ability of the male to remain small, live upon her and fertilise her eggs. The example of parasitic males partially violates the condition that the organism be unable to choose patch type. A larva that encounters a female can probably choose to avoid settling on her. Despite this, the absence of choice still largely applies because all larvae presumably do not encounter females (or do not have the choice to). Therefore, a larva that differentiated into a male too early would not be guaranteed to encounter a female.

Sex may also be environmentally determined in monstrillid crustaceans[12]. These parasitic copepods have life cycles similar to the nematodes discussed above in that the adults are free and mobile, and most of the larval growth takes place inside the host. As in nematodes, crowding in the host results in a preponderance of males.

Among higher plants, there are numerous examples of dioecious species where some individuals change sex between seasons of reproductive activity[4,5,17]; this provides evidence for the widespread occurrence of ESD in a group where it was previously given very little attention[18,19]. Also, there are many cases where male and female plants occupy different habitats, suggesting ESD or perhaps differential mortality by sex[17].

Several well-documented examples of plants with ESD are orchids of the genera *Cycnoches* and *Catasetum*[20,21]. Sunlight seems to be the resource which is differentially beneficial. Plants grown in bright sunlight become female, those grown in shade become male. Also, larger plants tend to be female. It is not clear why sunlight is more important to femaleness than to maleness (why should it be more important to seed production than pollen production?), but the pattern is well documented.

The arguments have been thus far directed towards maleness against femaleness in dioecious species. Natural selection should also favour the ability of a hermaphrodite living in a patchy environment to alter its allocation of resources between male and female function[7].

A sequential hermaphrodite should exercise control over the time at which it changes sex in accord with the above idea. As fitness of the second sex is often size dependent, it should often change sex according to size rather than age. For example, if an individual is reduced in size just before the expected size of sex change, it should remain the first sex until recuperated from the perturbation. Examples of this are well documented: in a polychaete (*Ophryotrocha puerilis*)[2] and a plant (*Arisaema triphyllum*[4,5,22,23]. Other examples of labile sex change, related to male against female fitness, are also known in fish (the labrid, *Labroides dimidiatus*)[24] and some marine gastropods (for example, *Crepidula*)[2,25].

In a simultaneous hermaphrodite, selection should favour the ability to alter the ratio of sperm (pollen) to ova (seeds) produced in response to environmental conditions[7] (as simultaneous hermaphroditism is commonly associated with immobility in the adult stage)[6]. Examples seem to be scanty, but the reallocation in monoecious plants due to factors such as nutrition or sunlight is well documented[4,5,26,27] (C. Smith, personal communication), particularly in the Russian literature[28].

Interestingly, this suggests that one selective advantage of monoecy in plants is that it allows the use of hormonal systems to control male against female allocation. This alteration is as simple as changing the ratio of male to female flowers. Supporting this idea is the observation that populations consisting of males, females and monoecious individuals are among the most common of all types of mixed populations in plants[28]. We interpret the males or females as hermaphrodites who have reallocated resources to one or the other sex. Such lability would seem to be less possible in plants with hermaphroditic flowers.

As this paper was being written we became aware that similar ideas were being developed in four other labs: K. E. Hoagland with protandrous molluscs; C. Smith for monoecious trees; L. Gilbert and M. Condon for protandrous vines; and C. Freeman, K. Harper and L. Klikoff for dioecious plants. We acknowledge their independent thought. We thank G. C. Williams, R. Shine, J. Cranford, J. Werren, N. Negus, P. Berger, G. H. Orians, J. Maynard Smith and Thomas Gibson for cooperation. This work was supported by a grant from the PHS.

Monogamy and sex change by aggressive dominance in coral reef fish

In several sequentially hermaphroditic coral reef fish, of which individuals first function as females and then males (protogynous hermaphroditism), dominant males can control production of other males by aggressive dominance over females[1–4]. Robertson suggested that socially controlled protogynous sex changes might operate only in species with a well defined polygynous social system "based on individual relationships"[2,3]. Further exogenous and endogenous factors may control sex change in species which school anonymously and in which the individuals lack special individual relationships. We describe here socially controlled proteandric hermaphroditism (individuals functioning first as males and then as females) in the anemone fish *Amphiprion*, in which females control production of females by aggressive dominance over males.

Amphiprion is widely distributed in the tropical and subtropical Indopacific region and is symbiotic with several sea anemones[5]. A 38-month field study of the ecology and social behaviour of *A. bicinctus* in Eilat, Israel (Red Sea) and a 2-month study of *A. alkallopisos* at Aldabra indicated that the breeding population of both consisted of large functional females with smaller functional males (Table 1). Gonadal examinations of 170 *A. alkallopisos* and 41 *A. bicinctus* showed that both species are born as males and females, but during ontogeny undergo functional male then female phases. Immature oocytes are always present in the testes of functional males (Fig. 1*b*), while functional females show no sign of testicular tissue.

Table 1 Mean and standard deviation of body length and wet body weight of the 10 largest males and females of *A. akallopisos* and *A. bicinctus*

	A. akallopisos		*A. bicinctus*	
	Male	Female	Male	Female
Length (mm)	73±3	97±5	113±7	129±6
Weight (g)	7.1±1.1	19.5±2.9	28.0±3.9	46.1±7.6

The typical social unit is a large female, a single smaller male and a varying number of subadults and juveniles, none of which is offspring of the adult pair. Both species

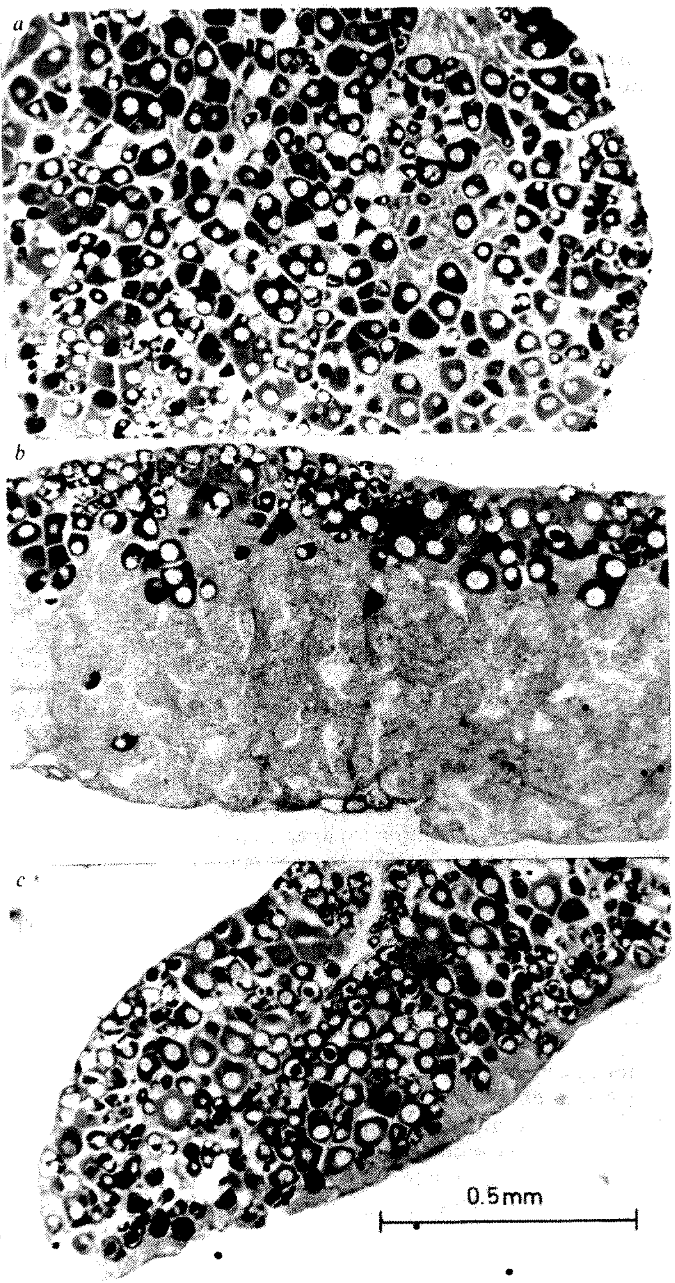

Fig. 1 Development of the testes of *A. akallopisos* according to the social status of the male. Males of approximately the same body length were selected. *a*, Previous beta-male (65 mm) 63 d after removal of the dominant female; *b*, β-male (70 mm) in functional state; *c*, γ-male (68 mm), development of mature testicular tissue suppressed.

live in closed monogamous groups based on individual recognition and individual pair bonding[6,7]. Several pairs of *A. bicinctus* remained on their home anemone for 3 yr without changing partners. Differences in group size result from differences in the ecology of occupied anemones (Table 2). Occasionally groups of up to 10 adult *A. akallopisos* are found on a single anemone colony. The average group size of *Amphiprion*, however, is restricted by the dimensions of the anemones to no more than two adults. "Monogamy by force" and permanent pair formation is favoured under these ecological limitations[7]. The largest and oldest individual of a group is always female and dominates the male, subadults and juveniles (Fig. 2). Subadult males are attacked by both sexes, the dominant alpha-female and high ranking males (Fig. 2). The beta-male particularly attacks the sexually competing gamma-male. In two groups of four *A. akallopisos* each, 53% of 861 and 64% of 559 observed, intragroup aggressive acts were performed by beta against gamma. The largest male prevents other males from spawning, thereby maintaining a monogamous social structure. The intragroup social pressure determines the gonadal development of the subdominants. Their testes are smaller and show little or no mature testicular tissue. Low ranking males are psychophysiologically castrated.

Sex reversal occurs in different social situations. After removal of a dominant female in an aquarium group of five mature *A. akallopisos*, the beta-male took the alpha-position and changed sex in less than 63 d (Fig. 1*a*). Sex change was also induced in field experiments by the removal of females from 24 pairs of *A. bicinctus*; six of the 24 males remained solitary while the remaining 18, joined by subadults of unknown origin, turned into females. The first of these females laid eggs after 26 d. To demonstrate the influence of dominance on sex change, different sized males were paired forcibly on empty anemones in the reef, and the gonads of six pairs were examined after 2 months and another 10 pairs after 6 months. The largest and dominant males always changed to females. Sex reversal also occurred in the absence of intragroup social pressure. Twelve functional males placed separately in the sea, six caged and six free, after 2 months showed various degrees of increased oocyte production. The uncaged males were more advanced towards becoming female in contrast to the caged males which were probably more stressed. Sex change was much slower in both experimental groups compared with dominant males which were paired forcibly with smaller males in the same conditions. The reversal of sex change from female to male could not be induced experimentally. Forcible pairing of functional females ($n=7$) resulted in death or severe injury to the subdominants. This study demonstrates socially controlled sex change by aggressive dominance. Females control the procreation of other females. They restrict the size of the breeding population and actively suppress males which are likely candidates for future females.

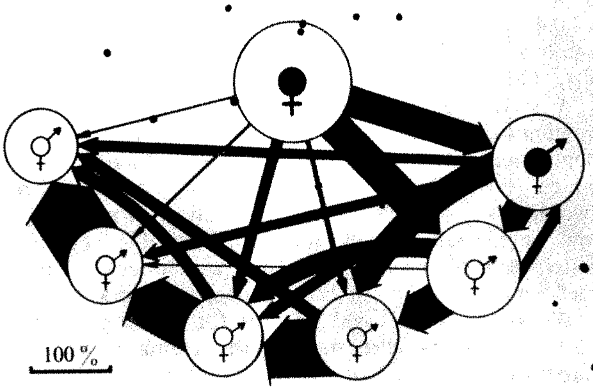

Fig. 2 Rank order by aggressive dominance in a group of seven *A. akallopisos*. An aggressive interaction is defined as a single chase, bite or frontal display. The relative body size of each individual is expressed as the square of the circle. The sex sign indicates the sex determination of the individual. A full circle denotes a functional, reproductive individual. The direction of the big arrows points to the receiver of the aggressive act. The distribution of aggressive acts of each individual is expressed as a percentage of total aggressive acts (= diameter of the arrow) which are performed by one individual against other group members. 752 intragroup aggressive acts were recorded.

If *Amphiprion* were gonochoristic (1 : 1 sex ratio), the chances for homosexual and heterosexual pairings resulting from randomly arriving larvae or juveniles or migrating adults would be equally distributed. Redistribution of sexually mismatched individuals would presumably result in migration of one of the individuals. Migration, however, increases the risk of predation. Furthermore, low population density and unpredictable distribution of the host reduces the chances of finding an anemone or an anemone with a partner of the opposite sex. These risks can be alleviated by socially controlled hermaphroditism where the largest and dominant animal controls the sex of the subdominants. In the case of death of a pair partner, this partner is easily replaced: the female through a fast sex change of the dominant male, the male from the stock of subadults or juveniles which arrive or live together with the adult pair. Juveniles are stunted but grow rapidly when an adult dies[5,7]. Furthermore, their ambisexual nature[8] allows formation of pairs by dominance when no adults are present. The young fish in the proximity of the breeding fish are always an insurance of potential males and females. Socially controlled sex change enables recruitment of breeding pairs independent of the sex of arriving young fish and without the necessity of leaving the host in search of a mate. Functional mates are produced whenever they are needed. It seems to be advantageous for a female to be larger than the male of the pair. A small *Amphiprion*-male can successfully fertilise and guard the eggs of a big female. Size increase of the male would not necessarily increase the reproductive success of the male. On the other hand, a larger female can produce more eggs than a smaller one (body weight and weight of ovaries are correlated in both species, *A. akallopisos* $r = 0.55$ ($P < 0.001$), *A. bicinctus*

Table 2 Comparison of both fish species and their host anemones

Species	Host anemones	Life style of host	No. of observed hosts	No. of adult fish per host	No. of juvenile fish per host	% Hosts occupied
A. akallopisos	*Radianthus ritteri*	Colonial	82 Colonies	2.6	0.6	100
A. bicinctus	*Gyrostoma helianthus*	Solitary	228	1.1	0.3	99.2
	G.quadricolor *R.koseirensis*	Solitary	122	—	0.9	69.7

The data for *A. akallopisos* were taken along transects in the lagoon channels of Pass Femme and Pass du Bois at Aldabra; for *A. bicinctus* in different reef zonations of the Nature Reserve in Eilat.

$r=0.45$ ($P<0.05$)). Therefore, the female of a monogamous pair benefits in reproduction by an increase in size. This could determine the direction of sex change.

A system of monogamy and sex change by aggressive dominance of females with them controlling the breeding population seems to be adaptive in ecological conditions which restrict group size to an average of not more than two adults. Probably the system evolved in response to the low population density and unpredictable, opportunistic distribution of the host anemones which occur in nearly all reef zonations from shallow to deeper waters.

We thank the Royal Society for making possible our visit to Aldabra; the staff of the Heinz Steinitz Marine Laboratory at Eilat for hospitality; Professor D. Schneider of the Max-Planck-Institute, Seewiesen for a histological laboratory; Professors E. Curio and R. Reinboth for critically reading the manuscript, and Professor W. Wickler and his students for useful discussions.

Behavioural divergences between mosquitoes with different inversion karyotypes in polymorphic populations of the *Anopheles gambiae* complex

STUDIES of the polytene chromosomes of the mosquitoes of the *Anopheles gambiae* complex have revealed fixed rearrangements based on paracentric inversions between all the six sibling species and inversion polymorphisms at the intraspecific level[1–5]. Inversion polymorphisms involve mainly chromosome arm 2R and are particularly frequent in the species formerly designated as A and B for which the names *An. gambiae* Giles, 1902 and *An. arabiensis* Patton, 1905 have been proposed[6]. These are the most ecologically adaptable members of the complex and the most important medically[7]. They are sympatric over the greater part of the African savannas. We report here on relationships between the behaviour of these mosquitoes and their inversion polymorphism.

Investigations were conducted in the Garki district (Kano State, Nigeria), a typical Sudan Savanna area located north-east of Kano where *An. arabiensis* generally outnumbers *An. gambiae* and breeding of both species is strictly seasonal, depending on rainfall. The main working hypothesis was that of a differential probability of contact with man and/or his domestic environment for the mosquitoes carriers of different inversion karyotypes. The availability of suitable polytene chromosomes in the adult ovarian nurse cells[8] enabled us to test this hypothesis directly by comparing inversion frequencies in female mosquitoes collected on the same day and in the same locality (a village in the Garki district) but in different situations (for example, indoors and outdoors). Preliminary evidence of non-random distribution of *An. arabiensis* with different 2R arrangements[9,10], obtained in 1972 and 1973, stimulated further comparative sampling in 1974 and 1975.

The 2R chromosome polymorphism of *An. arabiensis* from the Garki district involves six common paracentric inversions (Fig. 1). This complex system of overlapping and independent contiguous inversions permits no less than 15 different whole arm arrangements (2R, 2R*b*, 2R*bc*, 2R*d*, 2R*bd*, 2R*bcd*, 2R*a*, 2R*ab*, 2R*abc*, 2R*ad*, 2R*abd*, 2R*abcd*, 2R*be*, 2R*abe*, 2R*bf*), the frequencies of which cannot always be estimated because some of the 105 heterozygous combinations result in karyotypes which are very difficult to distinguish from one another (for example, 2R*a*/2R*bcd*, 2R*abc*/2R*d*, 2R*ad*/2R*bc*, 2R/2R*abcd*). Variation in 2R was therefore studied in terms of three sectional standards with the corresponding independent inversion systems $+^a \leftrightarrow a$, $+^b \leftrightarrow b \leftrightarrow bc$ and $+^d \leftrightarrow d$ and with two other overlapping inversions, *be* overlapping the last two systems and *bf* overlapping all three. As might be expected from close linkage existing between the independent inversions, obvious departures from random association were observed; these will be analysed separately.

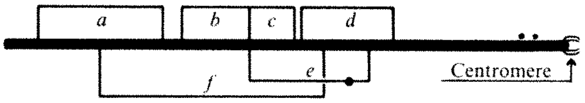

Fig. 1 Diagrammatic representation of 2R chromosome inversions in *An. arabiensis* from the Garki district. Inversion pairs *b-c* and *b-e* are interpreted as cases of extreme contiguity with one break point apparently coincident. The available evidence indicates that both *c* and *e* are based on 2R*b* as the inverted arrangements so far recorded are 2R*b*, 2R*bc* and 2R*be*, but not 2R*c* nor 2R*e*. Note that, in absence of 2R*b*, both arrangements 2R*bc* and 2R*be* could be interpreted as due to tandem inversions based on 2R. Inversion *f* is based on 2R*b* producing the 2R*bf* arrangement which overlaps with all other 2R inversions.

Table 1 compares the basic 2R chromosome variability in samples of *An. arabiensis* females collected in the village of Jirima during the 1973–1975 rainy seasons. The mosquitoes collected were: biting outdoors on donkeys (CD), biting outdoors on men (CM-OUT), biting indoors on men (CM-IN). resting indoors after blood meal (IR) and blood fed in exit trap (ET). Consistently significant differences were observed between these samples in the *a* and *b* inversion systems. The arrangements $+^a$ and *bc* were more frequent in CD, CM-OUT and ET samples than in the corresponding CM-IN and/or IR samples indicating that the mosquitoes with these chromosome types have a lower propensity to bite and rest indoors. In other words, these data point to a relationship between the 2R inversion polymorphism and differential endophily and endophagy. The substantial similarity of the chromosomal constitution of CD and CM-OUT samples indicates that differences in zoophily compared with anthropophily are not involved.

The 2R inversion polymorphism seems typically flexible (in the sense defined by Dobzhansky) as the alternative arrangements show wide seasonal and geographical changes in frequency with fairly obvious correlations with climatic and ecological conditions (Coluzzi *et al.*, unpublished). Thus those 2R arrangements which are more frequent in Jirima in outdoor samples of *An. arabiensis* ($+^a$ and *bc*) increase in frequency in southern more humid areas (Guinea Savanna), while those more frequent in Jirima in indoor samples (*a* and *b*) increase in frequency in northern more arid zones (Sahel Savanna). Data so far available for *An. gambiae* are strikingly similar. These findings suggest that the differential endophily is primarily an expression of differential climatic adaptations. Assuming a close integration of physiological and ethological responses to environmental heterogeneities, genetical variants adapted to an arid climate would be more prone to bite and rest indoors as the indoor environment generally shows a higher nocturnal saturation deficit than the outdoor environment.

Relationships between behavioural variations and inversion polymorphism have been demonstrated in the laboratory in *Drosophila* (see the review by Parsons[11]) and in *Anopheles*[12–15]. Our demonstration of such relationships in nature emphasises their evolutionary importance as well as their practical significance when dealing with a vector species. The practical implications are obvious when it is considered that a differential endophily and endophagy such as that recorded in *An. arabiensis*

Table 1 Frequencies (%) of 2R chromosome arrangements in samples of *Anopheles arabiensis* females obtained in the village of Jirima (Garki district, Kano State) during the 1973–75 rainy seasons

Sampling procedures used were: (1) Collection on donkeys outdoors (CD): mosquitoes were captured on 10–14 animals scattered in the village and exposed all the night. (2) Collection on men outdoors (CM-OUT): mosquitoes were captured on eight individuals from various parts of the village who had been exposed all the night. (3) Exit trap samples (ET): collections were made at 0600 h from 15 exit traps left on doors all the night. (4) Collection on men indoors (CM-IN): mosquitoes were captured on eight individuals exposed in closed huts (four per hut) all the night. (5) Indoor resting samples (IR): early morning (0600–0800 h) collections were made in 8–15 human habitations (huts) by pyrethrum spray capture or hand capture. The mosquitoes obtained from animal and human baits (mostly partly fed or unfed) were provided with a full blood meal on donkey during the same night. Blood fed specimens from all samples were kept in 200 ml paper cups (no more than 30 per cup) in favourable climatic conditions until 1400–1600 h and then processed for chromosomal examination either directly or after preservation in Carnoy fixative. No significant mortality was recorded during the maintenance period and more than 90% of the chromosome preparations were generally favourable for inversion reading.

*, †, ‡ Significant at the 0.05, 0.01 and 0.001 probability levels, respectively.

in the Garki district is expected to produce variations in vectorial efficiency and in the response to house spraying with insecticides. Some of the available data suggest that inversion polymorphism constitutes the basic genetical variability from which behavioural resistance to the insecticide may develop. Entomological investigations carried out by the WHO in the Garki district revealed important heterogeneities between *An. gambiae s.l.* from various villages, consistent with a positive association between exophily and residual density after insecticide (propoxur) spraying[16]. Such positive association clearly extends to the prespraying frequency of the 2R chromosome arrangements favouring exophily and exophagy in both *An. arabiensis* and *An. gambiae* (unpublished data).

With respect to evolutionary implications the non-random distribution of carriers of different arrangements implies some kind of ecotypic divergence among them, as suggested by Mayr[17] and supported by the work of Dobzhansky *et al.* in *Drosophila pseudoobscura*[18]. Thus the maintenance of inversion polymorphism could be based, at least in part, on annidation, in the sense defined by Ludwig[19]. A further consequence of non-random distribution of carriers of different arrangements might be their differential probability of shift to new or marginal ecological niches. This would mean a differential probability of forming isolates in which genetic reorganisation can be initiated, thus indicating the possibility of a causal involvement of inversions in speciation[20–22].

This work was supported by the WHO. We thank the Nigerian authorities and WHO staff in Kano and Kaduna for assistance, and Mr. G. Petrangeli for technical help.

Control of plant respiration through non-photosynthetic light action

THE effects of photosynthetically active light on carbon loss by plants are attracting much attention[1,2], but light action through mechanisms other than photosynthesis, though demonstrated as early as 1954 (ref. 3), is usually ignored in discussions of metabolic inefficiencies. Nevertheless, dim red light acting through phytochrome can clearly regulate the time course of CO_2 output in axenic cultures of *Lemna perpusilla*. The precise pattern of output under a given light schedule depends on the nitrogen source supplied; on nitrate or ammonium, the main daily peak seems to be timed in the same manner as some aspects of the photoperiodic control of flowering[4–6]. Essentially parallel results on O_2 uptake are reported here, indicating that the phenomena in question are respiratory in a reasonably strict sense.

Recording small changes in O_2 against the high background in air is essentially impossible over periods of days with methods currently available. Hence the intermittent-flow principle developed by Bruce and Street[7] for the detection of insects in stored grain was used. The change in gas concentration developed between periods of flow moves to the analyser as a 'bolus' when flow is resumed, producing a signal greater than that attainable otherwise. Comparing data so obtained with the earlier CO_2 results might be misleading, however, as intermittent flow might modify the patterns in some way. Thus all channels were also monitored with a CO_2 analyser. The first apparatus constructed had one sample channel and two blanks (without plants), and the second, two samples and three blanks. Most of the results considered are from the second version.

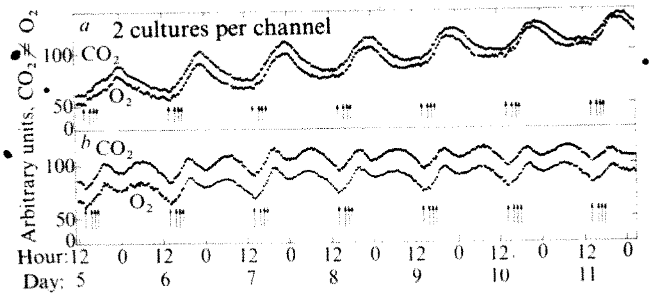

Fig. 1 Rates of O_2 uptake and CO_2 output by cultures on nitrate or aspartate as sole N sources and entrained to 4-h skeleton main light periods. Points are at 0.5-h intervals, each being assigned to the hour or half-hour immediately preceding its occurrence. The clone used was originally obtained from Dr Elias Landolt as *Lemna perpusilla* 6746, but it has also been described as *L. paucicostata*[23]. Stocks were maintained under continuous cool white fluorescent light (about 3,200 lx) at 25–27 °C, on a complete mineral medium supplemented with sucrose, yeast extract, tryptone and EDTA (refs 5, 6). Experimental cultures established by transferring batches of fronds from stock cultures to the media being tested were then capped for connection to the air streams, all substantially as in ref. 5 except that 125-ml Erlenmeyer flasks with 50 ml of medium were used instead of bottles. Nitrogen-free Z medium supplemented with either aspartic acid (*a*) or KNO_3 (*b*) at 15 mM was used, with the aspartate medium sterilised by filtration rather than autoclaving. As before, brief exposures to dim red light (cool white fluorescent screened with Rohm and Haas red 2444 Plexiglas to yield 10–35 $\mu W\ cm^{-2}$ at plant level) were used to simulate main light periods. In the results above, 15-min exposures starting at 1400, 1545, 1645 and 1745 h daily, local time (arrows), represent a 4-h main light period; exposures at 1400, 1715, 2030 and 2345 h would simulate a 10-h main light period[6]. Constant temperature in the experiment shown was about 27 °C. Cultures contained 0.2–1.4 g fresh weight of plant during the experiment, and were held in conditions being tested for 5 d before connection to the intermittent-flow gas analysis system. Each blank and sample channel received, in succession, 4 min of air flow at 50 ml min^{-1} followed by 26 min without flow. The recorded analyser outputs obtained show the samples as spikes separated by the blank values. The sample-blank differences plotted above thus represent the rates of change in O_2 or CO_2 in relative units. A cold trap (−18 °C) was interposed before the analysers to prevent water vapour from reaching them. Oxygen was determined by magnetic susceptibility using a Beckman G-2 oxygen analyser with a reversed range, nominally 21.0–20.5% (5,000 p.p.m. full scale). The infrared CO_2 analyser, a LIRA Model 303 (Mine Safety Appliances Co.) also had a full-scale range of 5,000 p.p.m. Given the intermittent-flow mode, the actual relationship between the arbitrary O_2 and CO_2 units plotted is uncertain, and will of course vary depending on the relative drifts of the two analysers. Rough calculations suggest that culture size would have to be increased 60- to 100-fold in order to obtain comparably useful data from, for example the automatic recording respirometer described by Dilley *et al*[24]: a detailed description of the present system and an assessment of its quantitative aspects will be presented elsewhere (Hillman and Tempel, in preparation). The timing of each peak can be estimated by inspection, or objectively, by summing the times of the eight or more highest values during the period in question and dividing by the total number of values, in accord with the following rules. The time of the highest value, or the times of the several highest (values of rank α) are taken first. To these are added the times of all values one unit less (rank β) and then of all of ranks γ and lower, as necessary, until at least eight values have been summed; but if one value of any given rank is included, then all others of that rank not separated from it by two or more unused lower values are also included. As an example, the peak time for the O_2 values on day 10 on nitrate, above, combines the values at 0600, 0630 and 0730 h (rank α), those at 0530, 0700 and 0800 h (rank β) and those at 0400, 0430, 0500, 0830 and 0900 h (rank γ) for a total of 11 values giving a peak time of 6.50 h after midnight, which is 16.5 h after the start of the light period, or 12.5 h after the start of the dark period.

Figure 1 summarises a typical experiment under 4-h skeleton light periods on aspartate and nitrate media. The courses of O_2 uptake and CO_2 output are essentially parallel throughout, while the patterns on the two media differ. On aspartate, there is one peak per day and on nitrate, two; earlier work with CO_2 output led to the designation of the second daily peak on nitrate as the main peak.

The time of each main peak was estimated in both the experiments shown in Fig. 1 and another performed the same way. The means and standard errors calculated from the combined experiments place the peaks in O_2 uptake on aspartate and nitrate at 7.9±0.32 and 16.1±0.18 h, respectively, after the start of each light period. The corresponding peaks in CO_2 output occur at 8.1±0.35 and 16.6±0.18 h, times not significantly different from those for O_2. All these values, as well as the patterns themselves, are essentially those obtained earlier for CO_2 output monitored by continuous flow[5,6].

In the CO_2 output data referred to, changing the length of the main light period shifts the main peak on nitrate medium. The line relating the time during the dark period at which that peak occurs to the length of the light period has a slope of −0.425±0.049 for skeleton main light periods from 4–10 h long[6]. That is, lengthening the light period by 1 h causes the peak to occur slightly less than 0.5 h earlier, as measured from the start of the dark period, which is a delay of slightly more than 0.5 h from the start of the light period. To determine whether the same relationship holds for O_2 uptake, time-course data were obtained on nitrate medium under schedules with 4- and 10-h skeleton light periods in the same experiment. For the 6 d recorded, the mean time of the main peaks under the 4-h skeleton was 16.4±0.08 h after the start of the light period, and under the 10-h skeleton, 19.5±0.18 h after the start of the light period. Subtracting the light-period lengths, this means that the 4- and 10-h main light periods place the peaks at hours 12.4 and 9.5, respectively, of the corresponding dark periods. The slope calculated from the 12 values of this experiment is −0.484±0.032. A similar calculation using values from two successive experiments carried out on the single channel version of the apparatus gave an estimated slope of −0.440±0.075. Neither of these slopes differ significantly from those derived from earlier data on CO_2 output and on flowering[6], but, like those, they do differ significantly ($P = 0.01$) from both 0 and −1.

The light effects reported earlier are probably exerted entirely through phytochrome[4,5]. Perhaps the most striking single phytochrome phenomenon is that of the 'red, far-red switch'. That is, on a nitrate medium, under a basic schedule of one 0.25-h light exposure every 24 h, cultures previously entrained to far-red respond to red by a near-doubling of CO_2 output in 6 h. Conversely, cultures previously entrained to red respond to far-red with a sharp drop in CO_2 output, even though the steady-state pattern elicited by daily far-red would give a peak shortly after the light exposure[5]. The experiment presented in Fig. 2, which may be compared to Fig. 4 in ref. 5, indicates that precisely the same effects are observed in O_2 uptake.

The fact that O_2 uptake by *L. perpusilla* is essentially parallel to CO_2 output in all conditions tested means that the use of this system to investigate photoperiodic timing[5,6] must proceed through an analysis of respiratory pathways rather than nonrespiratory decarboxylations. Beyond this rather specialised point, however, these data also lead to the conclusion that a substantial proportion of the respiration of at least one higher plant may be affected by aspects of the light regime unrelated to photosynthesis.

The applicability of this conclusion to plants in general is suggested by several considerations. Leopold and Guernsey[3] observed short-term phytochrome effects on O_2 uptake in tissues of several species. Few similar studies (for example refs 8–11) have appeared since, but there is abundant, if somewhat contradictory, recent evidence for phytochrome-mediated changes in the levels of various respiratory intermediates[12–15]. The nightly pattern of CO_2 output—presumably respiratory—by *Chenopodium polyspermum* changes within a few days of change in the length of the light period[16]. In addition, phytochrome clearly mediates light effects on rhythms in plant respiration, respiratory enzymes and intermediates[17]. Miyata and Yamamoto[18] suggested that rhythms in *Lemna gibba* respiration involve variations in the activity of the pentose phosphate pathway, while in *Chenopodium rubrum*, Deitzer *et al.*[19] found distinct rhythms in enzymes of that pathway on the one hand and of the tricarboxylic acid cycle on the other. Thus, modifications of the relative activities of these two metabolic systems might underly the present results.

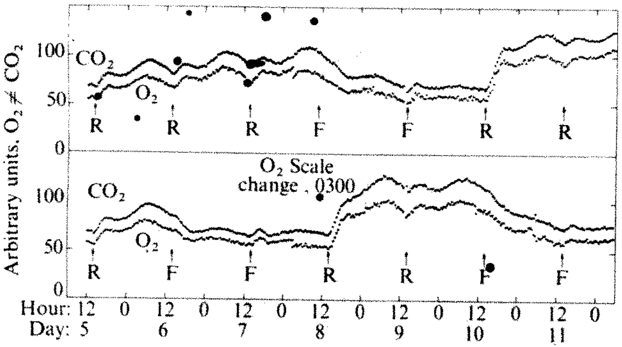

Fig. 2 Rates of O_2 uptake and CO_2 output by cultures on nitrate as sole N source and entrained originally to 0.25 h red light every 24 h, then given red (R) or far-red (F) as indicated. Light sources as in ref. 5. Other details as in Fig. 1. Gaps in the data represent recorder malfunction.

The fraction of total respiration under the control studied here has been estimated[5,6] at from 30% for daily entrainment patterns (Fig. 1) to 50% in a 'red, far-red switch' (Fig. 2). These may be minimal estimates. Unpublished data indicate that respiration in most of the cultures used is soon limited by crowding, which probably explains the apparent decrease in the proportion of control with time (Fig. 1 of ref. 5). While the parallelism between O_2 uptake and CO_2 output is extremely close in these data, it may not be perfect. The ratio of the arbitrary values, or apparent respiratory quotient, changes slightly in response to experimental variables. Further work will be required to establish that these observations do not result merely from differing gas solubilities or other nonbiological factors.

Finally, although the term photorespiration has become virtually synonymous with effects of bright light on the consumption of current or very recent photosynthate, a comprehensive view of metabolic regulation should no longer ignore the fact that overall respiratory rate can be massively, and on occasion rapidly, modified through other light actions. Since these actions may be exerted at times remote from those of actual illumination, and at low energies, the retention of quotation marks in the phrase (and concept) of 'dark' respiration[2] seems particularly wise. The fact that the respiratory rhythm in *Lemna gibba* seems to be correlated with changes in azide sensitivity[18] is of particular interest since inhibitor-resistant electron transport may be wasteful with respect to phosphorylation[20]. Thus, in the context of current concern with metabolic efficiency and plant productivity[1,2], this work directs renewed attention to light action on phytochrome and to its timing—the photoperiodic aspects of the daily light regime. And although the effects of blue light on *Lemna* respiration are probably mediated entirely by phytochrome[4], the situation in general could prove to be even more complex, in view of recent evidence for physiological photoreception by flavin-cytochrome b couples in both fungi[21] and higher plants[22].

I thank Neal Tempel for building the assay system and contributing to its design, Nancy Bernius for technical assistance, and D. T. Canvin, G. F. Deitzer, G. Hind, R. S. Loomis and I. Zelitch for comments on the manuscript. This work was carried out under the auspices of the US ERDA.

Viral contamination of bovine foetal serum and cell cultures

THE presence of adventitious viruses in cell cultures is well recognised[1], and when the cultures are of primate origin there are serious hazards for the production of human viral vaccines[2]. This is one reason for the increasing use of bovine cell cultures. These cultures, however, are not free from viral contamination[3]. We found that calf kidney (CK) and calf testis (CT) cells were often infected by non-cytopathic mucosal disease virus (MDV): the cells seemed morphologically healthy but nearly all showed fluorescence with MDV antiserum and rabbit-anti-bovine conjugate. We report here that both the cells and foetal calf serum, an essential growth factor of cell culture medium, are sources of the virus.

MDV (also known as bovine viral diarrhoea virus), a member of the family Togaviridae, is antigenically related to hog cholera virus[4] and morphologically similar to rubella virus[5]. The role of FCS, as a source of contamination by MDV, was examined by growing CT cells in medium supplemented with either unheated or heated FCS. Heated FCS had been held at 56 °C for 30 min because these condition inactivated MDV. The incidence of infection of each cell batch grown in unheated FCS was compared with the incidence of infection of the same cell batch grown in heated FCS (Table 1). Fourteen batches of CT cells grown in five batches of FCS were examined. All of the 14 batches of cells grown in the presence of unheated FCS became infected by MDV. In contrast, when grown in the presence of heated FCS, only one of the 14 batches became infected by the virus.

Each batch of CT cells was screened for infection by MDV at several different passage levels (Table 2). Viral infection was not usually detected until passage 6 when 70% of cell batches grown in unheated FCS showed MDV fluorescence. Only 25% of cell batches showed evidence of MDV infection at passage 3.

Table 1 Batches of bovine cell cultures showing MDV fluorescence and grown in the presence of unheated or heated FCS

Cell	FCS	No. positive	No. tested
CT	Unheated	14	14
	Heated	1	14
CK	Heated	10	63
MDBK*	Unheated	1	1‡
BT22†	Unheated	1	1‡

The indirect fluorescent antibody test was carried out using antiserum raised in a gnotobiotic calf against the NADL (National Animal Diseases Laboratory) strain of MDV, and a rabbit-anti-bovine serum conjugated with fluorescein (Nordic Immunology). Pre-inoculation serum was used as a control of fluorescence. CT and CK cell cultures were derived from 1–15 d-old calves, freshly slaughtered each week; trypsinised tissues were seeded into 20-oz bottles and cultured in Eagle's basal salts medium supplemented with 7.5% commercial FCS. Each batch of CT cells was subcultured for up to 15 passages, and CK cell cultures were subcultured until the secondary passage.

*Madin Darby bovine kidney.

†Bovine turbinate.

‡Continuous cell lines; therefore only one 'batch' could be examined.

The other possible source of non-cytopathic MDV, the cells themselves, was examined by fluorescent antibody staining of CK cells which were grown in the presence of heated FCS and subcultured only once. Ten of 63 cell batches examined showed MDV fluorescence. Two continuous cell lines, MDBK and BT22, were also found to be infected by non-cytopathic MDV (Table 1).

Specificity of the fluorescent antibody test was confirmed by neutralisation tests. The agent isolated from CT cells was able to infect uncontaminated CK cells. But when the agent was first treated with antisera to MDV (either a Weybridge reference serum or an antiserum raised at Compton by hyperimmunisation of a gnotobiotic calf with the NADL–MDV strain), CK cells did not become infected. Thus antisera to MDV neutralised the agent isolated from CT cells; no neutralisation occurred with pre-immune control serum.

The results of fluorescent antibody staining were also supported by tests for interference, which were carried out by a plaque technique. A standard inoculum of cytopathic MDV was titrated on Petri dishes of CT cells, which fluorescent antibody staining had shown to be infected by non-cytopathic MDV. The number of plaques produced by the cytopathic virus was compared with the number produced by the same viral inoculum titrated on known, uncontaminated CT cells (Table 3). No more than a twofold reduction in plaque number on the contaminated cells was found.

Table 2 CT cell cultures showing MDV fluorescence at various passage levels

FCS*	Results of FA†	Cell passage no. 1	3	6	9	12	15
Normal	No. positive	0	3	10	8	7	6
	No. tested	6	12	14	12	8	6
Heated	No. positive	1	0	1	1	1	0
	No. tested	11	12	14	12	8	6

*Half of each batch of CT cells was grown on medium supplemented with unheated FCS and half on medium supplemented with heated FCS.

†Indirect fluorescent antibody staining as in Table 1.

The conventional interference test, used for screening FCS and bovine cells, relies on detection of a visible inhibition of virus-induced cytopathic effect. This method is obviously not as sensitive as a quantitative plaque technique and probably would not detect the relatively low level of interference as noted in Table 3.

The results indicate two different sources of contamination by non-cytopathic MDV. First, MDV may be found in commercially produced FCS because heat treatment of serum reduces the incidence of infection of CT cells from 100% to 10%. Second, MDV may be indigenous to bovine cells; approximately 20% of batches of CK cells grown in heated FCS for only two passages, and on serum shown to be free of MDV by culture of CT cells, are infected by MDV. CT cells grown in normal FCS have to be subcultured several times before showing evidence of MDV infection, and so the viral inoculum in FCS is low.

Table 3 Comparison of number of plaques produced by cytopathic MDV on uninfected CT cells with number of plaques produced on CT cells infected by non-cytopathic MDV

Cell batch/ passage no.	Mean no. plaques per plate ± s.e. Uninfected	Infected	Student's t test
60/9	48±8	24±7	5.131
60/13	21±7	15±2	1.774*
63/6†	54±12	26±3	4.704
	29±8	17±4	2.998
	30−5	18−5	3.485

Standard inocula of cytopathic MDV (NADL) were titrated on Petri dishes of CT cells either contaminated or uncontaminated by non-cytopathic MDV. Mean numbers of plaques produced on five replicates of contaminated CT cells were compared with mean numbers of plaques produced on the same cells but which were uncontaminated. Student's t test, $P<0.05$, 4d.f.

*All comparisons except this one showed significant differences.

†Three different inocula of cytopathic MDV.

In the above experiments, CT cell cultures were exposed to five different batches of FCS obtained from one commercial supplier: all batches contained MDV. These results indicate a much higher incidence of contamination than reported previously[6,7], and illustrate the inadequacy of commercial screening methods. This inadequacy may be explained by the relative insensitivity of the interference test, often the only method used to detect non-cytopathic MDV, and by the fact that the amount of virus in FCS is probably small.

The presence of MDV in FCS is explained by the ability of the virus to infect the bovine foetus *in utero*[8]. A main supplier of FCS is Australia where infection by MDV is widespread: in 1964 it was shown that approximately 60% (374/625) serum samples taken from cattle throughout the country had neutralising antibodies to MDV[9]. The incidence of foetal infection is unknown, but because each batch of FCS represents a pool of serum taken from about 500 foetuses (for an average batch of 170 l), contamination of a batch requires only a 0.2% incidence of foetal infection by MDV.

Infection of bovine cell cultures by non-cytopathic MDV has particular significance for the production of viral vaccines. Tamoglia[10] tested live infectious bovine rhinotracheitis vaccines from all licensed producers in the United States and found that 8% were contaminated by MDV. Vaccination with such vaccines may give rise to abortions since transplacental infection by MDV can cause death and malformations of the foetus[11].

The importance of contamination by MDV with regard to human viral vaccines is unknown, but measles virus vaccine[12] and a potential respiratory syncytial virus vaccine[13] are produced on bovine kidney cells grown in the presence of unheated commercial FCS. Contamination of viral stocks also has important implications for experimental virology. For example, in a trial designed to assess the clinical responses of calves to infection by respiratory syncytial (RS) virus[14], the RS viral inoculum, grown in CK cells, was found to contain MDV. If MDV had not been detected, the clinical reactions of inoculated animals would have been attributed solely to RS virus.

Regular screening of bovine cell cultures is essential if viral stocks are to be kept free from MDV. We suggest that the fluorescent antibody test, using a monospecific antiserum, is the most reliable method available for detecting non-cytopathic MDV in cell cultures. Moreover, if FCS is heated before use, the incidence of contamination of cell cultures by MDV will be greatly reduced.

We thank Mrs N. J. Jebbett for assistance in fluorescent antibody staining. P.A.N. is supported by the Animal Health Trust.

Neonatally tolerant mice fail to react against virus-infected tolerated cells

IN mice, immune effector functions mediated by thymus-derived lymphocytes (T cells) are restricted by the major histocompatibility (*H–2*) gene complex (see ref. 1 for review). Thus, virus-stimulated cytotoxic T cells are specific for both viral antigen(s) and self-cell-surface structures coded in the *K* or *D* region of *H–2* (refs 2, 3). Two general hypotheses have been proposed to explain *H–2* restriction[2–5]. First, T cells possess two independently, clonally expressed, but linked receptors, one for the foreign antigenic determinant and one for the relevant self-marker (dual receptor model); second, T cells have a single clonally distributed receptor for a complex of foreign antigen plus self or for virally altered self-markers (altered self model). To date no conclusive proof exists for one hypothesis or the other. The altered self model is the simpler concept of the two; on the other hand, the fact that cytolytic interactions against minor histocompatiblity antigens are *H–2* restricted and that the idiotypic determinants of T cell-receptors are identical with those of immunoglobulins of the same specificity[6–8] are probably more compatible with a dual receptor.

In both models, but particularly in the dual receptor model, defining the relationship between tolerance against alloantigens and the capacity to recognise the same alloantigens as self or alternatively as altered self seems to be crucial for understanding of the mechanisms of T cell recognition. Experiments with $H\text{–}2^k/H\text{–}2^d$ radiation chimaeras, that were reconstituted with one parent's haemopoietic stem cells revealed that separate groups of T cells were specific for virus plus $H\text{–}2^k$ or virus plus $H\text{–}2^d$ (refs 9–11). The absence of alloreactivity (presence of tolerance) appeared to parallel presence of self-recognition (as proposed in the dual receptor model), or alternatively the presence of recognition of altered self. The present experiments were designed to evaluate whether tolerance to alloantigens and reactivity to tolerated self plus virus parallel each other when tolerance was maintained with minimal chimerism as in the classical Billingham–Brent–Medawar[12] neonatally tolerant mouse model. The results revealed no such correlation.

Neonatal A.AL ($H\text{–}2K^k$) mice were injected into the orbital vein with spleen and bone marrow cells of (A.AL × A.TL)F$_1$ ($H\text{–}2K^k/H\text{–}2K^s$) origin. (W. Streilein and J. Klein, in preparation). Eight weeks later, survivors were grafted with A.TL skin. Mice that did not reject the skin grafts were considered as tolerant ($H\text{–}2K^k$ tolerant to $H\text{–}2K^s$). Tolerant and conventional A.TL ($H\text{–}2K^s$), SJL ($H\text{–}2K^s$) and B10.BR ($H\text{–}2K^k$) mice were then infected with vaccinia virus, and their spleen cells were assayed for virus-specific cytotoxic activity on vaccinia virus infected and uninfected syngeneic or allogeneic target cells 6 d later (Table 1). The degree of chimaerism of the tolerant mice was determined by lysing of their lymphocytes in the cytotoxic test with antisera against *H–2K* haplotypes. Chimerism in the tolerant mice was below 5% since specific anti $H\text{–}2K^k$ (K-603) antiserum + C′ killed > 95% of lymphocytes from conventional A.TL mice, lysed less than 5% cells from tolerant mice[13,14].

Although vaccinia virus immune spleen cells from tolerant mice lysed infected $H\text{–}2K^k$ L cells to a high degree they failed to lyse any of the three infected $H\text{–}2K^s$ targets. The $H\text{–}2K^s$ targets were lysed very efficiently by A.TL or SJL immune lymphocytes. Therefore, the efficiency with which virus immune spleen cells from allogeneic or tolerant mice lysed the $H\text{–}2K^s$ targets must be at least 50 times lower than that for immune cells from A.TL or SJL.

This result could suggest the presence of some suppressor mechanism in the tolerant mice's immune spleen cells that prevent expression of virus-specific cytotoxic activity against the infected targets of the tolerated *H–2* type. Yet the cytolytic activity of virus specific T cells specific for K^s was not diminished significantly when they were mixed with excess numbers of cells from mice tolerant to K^s; any effects observed were comparable to interference caused by unrelated K^d spleen cells from B10.D2 mice that were not tolerant to K^s (Table 2). Thus suppression seems to be unlikely at least at the level of the effector cell. This experiment, however, cannot exclude the possibility that suppressive mechanisms act during induction of the cytotoxic lymphocytes.

The difference of the results obtained in mice that were rendered tolerant neonatally and the F1 radiation chimeras may reflect different mechanisms of tolerance induction and/or maintenance. Since these mechanisms are poorly understood this argument remains open. A possible difference may be presence or absence of suppression. Alternatively, the data may suggest that the generation of self plus virus-specific cytolytic T cells is, besides being virus-dose dependent, also dependent on the dose of the relevant self-markers. In P ($H\text{–}2^k$)→F$_1$ ($H\text{–}2^k/H\text{–}2^d$) radiation chimeras, when the syngeneic and the tolerated allogeneic haplotypes are both expressed in great amounts, virus-specific cytolytic activity is generated against virus in association with both

Mice were infected with about 10^7 plaque forming units (PFU) of vaccinia virus (WR strain). The mice were killed 6 d later and spleen cells assayed for cytotoxicity at the spleen cell to target cell ratios indicated. Since only the constitution of the K region of the H–2 complex is relevant to this experiment, the constitution of the other regions is not shown. Where no values are shown the values were not determined.

*L929 continuous line fibroblast cells, SJL secondary fibroblasts and SJL or A.SW peritoneal macrophages were labeled with ^{51}Cr, washed and infected with vaccinia virus at a multiplicity of about three for 3 h at 37 °C. The % of ^{51}Cr released was determined after 6 h incubation at 37 °C. The standard errors did not exceed 2.2 for all targets tested.

†Significantly greater than controls ($P < 0.01$).

‡Not significantly different from normal cell controls or medium.

haplotypes. In the neonatally tolerant mice studied here, the chimaerism is minimal, sufficient to maintain tolerance, but not to an extent where during infection appreciable amounts of cells would express virus plus alloantigen to trigger measurable quantities of cytotoxicity against these specificities.

Reassembled HVJ (Sendai virus) envelopes containing non-toxic mutant proteins of diphtheria toxin show toxicity to mouse L cell

PREVIOUS studies from this laboratory have described the preparation, from HVJ virions solubilised with a non-ionic detergent, of a reassembled envelope fraction free of nucleocapsids. Such reconstituted envelopes still retain neuraminidase, haemagglutinating, cell fusion and haemolytic activities[1-3]. Since intact virions release their nucleoproteins into the cytoplasm after fusion with mammalian cells, it seemed possible that any given macromolecule contained within such a reassembled viral envelope might be introduced into susceptible mammalian cells by this means. We report here the successful application of this method to the introduction of CRM45, a non-toxic mutant protein related to diphtheria toxin[4], into mouse L cells, a strain that is normally toxin resistant. Although CRM45 is a potent NAD : elongation factor 2-ADP ribosyl (NAD : EF2-ADPR) transferase[5,6] and thus blocks protein synthesis in eukaryotic cell extracts, it is non-toxic for animal cells because it lacks a C-terminal sequence of amino acids necessary to bind to susceptible cell membranes and thus cannot reach the cell interior[7]. If a few molecules of CRM45 could be introduced into the living cell cytoplasm, they should block protein synthesis and kill the cells. This has now been accomplished by fusion of CRM45-containing reassembled HVJ envelopes with cultured mouse L cells.

HVJ virions were collected by centrifugation, resuspended in buffer containing CRM45 and divided into two portions. Non-ionic detergent Nonidet P40 (NP40) was added to one portion to solubilise the virions; it was not added to the other which served as a control. After ultracentrifugation of the solubilised virions to remove nucleocapsids and other insoluble material, the envelopes were reassembled by dialysis against phosphate buffered saline (PBS) to remove the detergent and then applied to a Sephadex G200 column to separate reassembled envelopes or native virions from free CRM45 protein. The reassembled envelope fraction was eluted from the gel with the void volume as a single sharp peak (Fig. 1). NAD : EF2-ADPR transferase activity and haemagglutinating activity were both associated with this peak. A peak of free CRM45 was found in fraction 41 and thus was well separated from the reconstituted envelopes. The CRM45-containing reassembled envelopes were collected and resolubilised with NP40. Resolubilisation resulted in a 3.2-fold increase in enzymatic activity (Table 1). These observations suggest that about 70% of the CRM45 was inside the reassembled envelopes and about 30% was tightly bound to the membrane with its enzymatically active fragment A moiety[8,9] exposed to the outside. About 2% of the total added CRM45 was recovered with the envelope fraction. The control HVJ virions, suspended in CRM45 at the same concentration, were also filtered through Sephadex G200. The native virion fraction emerged with the void volume as expected, but contained very little ADP ribosylating activity. There was no further increase in enzymatic

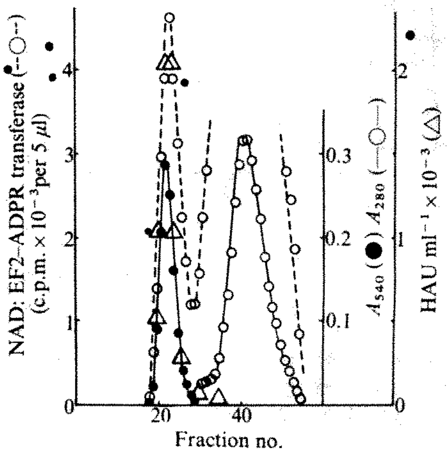

Fig. 1 Separation of reassembled CRM45-containing envelopes from free CRM45. Purified HVJ virions (about 7×10^4 HAU) were collected and resuspended in 1 ml 0.005 M Tris buffer at *p*H 7.4 containing 5 mg ml^{-1} CRM45 and divided into two equal portions. To the first was added NP40 at a final concentration of 0.25%; the other served as a control. After 15 min at room temperature, the solubilised virions were centrifuged at 40,000 r.p.m. for 60 min to remove nucleocapsids and other insoluble material. The resulting supernate was dialysed at 4 °C in a Neflex tube against PBS with the buffer changed each day for 3 d. The reassembled dialysed envelope preparation was then chromatographed through Sephadex G200. Ten drop fractions (0.73 ml) were collected and the absorbance of each fraction was measured at 280 nm and at 540 nm. The HVJ virions to which no NP40 had been added were suspended in 0.5% CRM45 solution and dialysed against PBS and chromatographed through Sephadex G200 in the same manner. NAD:EF2-ADPR transferase activity of each fraction was assayed using 2 μl, 5 μl and 10 μl samples by a slight modification of the method of Gill and Pappenheimer[8]. Haemagglutinating activity, determined using chicken erythrocytes, was expressed as HAU ml^{-1}.

Table 1 Enzymic activity of CMR45-containing reassembled envelopes before and after treatment with NP40

Pooled fractions	A_{540}	HAU ml^{-1}	NAD:EF2-ADPR transferase before NP40 c.p.m. per 5 µl	NAD:EF2-ADPR transferase after NP40 c.p.m. per 5 µl
Reassembled envelopes containing CRM45	0.225	1,500	4,115	12,963*
Intact virions, preincubated with CRM 45	1.5	16,000	187	150

*This activity increased about twofold as did that of free CRM45 after brief controlled treatment with trypsin (see ref. 4).

Fractions 21–24 of Fig. 1, both from gel filtration of CRM45-containing reassembled envelopes and from the intact HVJ virions, were pooled. The pooled volume was 2.9 ml in each case. Both suspensions were then solubilised with NP40. Assay for NAD:EF2-ADPR transferase activity was carried out on 2 µl and 5 µl samples after threefold dilution, both before and after treatment with NP40 as described in the legend to Fig. 1.

activity after solubilisation of the virions with detergent (Table 1). Thus CRM45 neither enters the intact virions nor binds non-specifically to their surface.

The enzymatic activity per ml of CRM45-containing envelope suspension was equivalent to about 20 μg ml^{-1} of diphtheria toxin. The toxicity of the suspension was tested using mouse L cells known to be at least 10,000 times as resistant to intact toxin as HeLa cells. Table 2 shows that 70% and 92% of L cells were killed after short exposure to the CRM45-containing HVJ envelope suspension diluted so as to contain respectively only 10 and 100 haemagglutinating units (HAU) per ml. The same amount (HAU) of either reassembled virion envelopes, or of ultraviolet-killed virus, whether added alone or mixed with free CRM45, showed no toxicity at all for L cells when tested under the same conditions. It is clear that CRM45-containing reassembled HVJ envelopes are toxic for a mammalian cell line. Further experiments suggest that the method is likely to prove of general use for introducing macromolecules into the cytoplasm of living mammalian cells. We experienced no difficulty in introducing ^{125}I-labelled IgG into mammalian cell lines (L cell, Ehrlich ascites tumour cell and KB cell). The yield of IgG trapped within the reconstituted viral envelopes was about the same as for CRM45.

Table 2 Toxicity of CRM45-containing reassembled HVJ envelopes for mouse L cells

Sample	Number of surviving colonies per dish 100 HAU ml^{-1}	Number of surviving colonies per dish 10 HAU ml^{-1}
Reassembled CRM45-containing envelopes	12	44
Intact HVJ virions plus CRM45 (1 µg ml^{-1})	132	129
Reassembled empty envelopes plus CRM45 (1 µg ml^{-1})	132	129
Reassembled envelopes	142	155

Two hundred L cells suspended in 2 ml of MEM medium containing 10% calf serum were added to 30 mm plastic Petri dishes and incubated for 7.5 h at 37 °C. The cells were then washed once with 2 ml chilled buffered salt solution (BSS, see ref. 15) before 0.5 ml of the chilled sample was added. After 20 min at 4 °C they were brought to 37 °C and incubated a further 20 min. Two ml culture medium was added and incubation continued for 3 h at 37 °C. The medium was then exchanged for fresh medium and the cells were cultured for 7 d. The cells were finally fixed with methanol and stained with Giemsa. Colony counts were averages of duplicate plates. Control dishes contained 130 and 132 colonies. To prepare samples for test, the pooled fractions of reassembled HVJ envelopes of Table 1 were diluted in BSS 15 and 150 times to final concentrations of 100 and 10 HAU ml^{-1} respectively. Both ultraviolet-killed HVJ virions and their envelopes reassembled in the absence of CRM45 were diluted to 100 and 10 HAU ml^{-1}. CRM45 was added to the diluted controls at a final concentration of 1 µg ml^{-1}.

There are many reports of introduction of substances into living mammalian cells, the most frequently used techniques being the liposome[10–12] and erythrocyte ghost–HVJ methods[13,14]. As the procedures for reassembling the envelopes are mild without any drastic mechanical steps and the reassembled HVJ envelopes have specific binding sites to susceptible cells, we believe that the method we have described is also effective for introducing proteins into the cytoplasm of living mammalian cells.

T lymphocyte responses to *Mls* locus antigens involve recognition of *H-2 I* region gene products

THE major histocompatibility complex (MHC) in the ninth linkage group of the mouse encodes antigens that stimulate strong alloreactions[1]. *In vitro* studies have focused on two such reactions, both mediated by T lymphocytes. Cytotoxic T cells can recognise products of the MHC *H-2K* and *D* regions (KD antigens), and can be distinguished by their Ly antigen phenotype from the non-cytotoxic T lymphocytes that give their strong proliferative responses in mixed leucocyte culture (ref. 2) (MLC). These latter cells respond primarily to *H-2 I* region gene products[1,2]. The products of a second genetic locus in the mouse also stimulate strong MLC responses. This *Mls* locus[3] behaves as a single autosomal dominant gene mapping in linkage group 13. It has been defined by studying MLC reactions between MHC identical strains of mice. Interestingly, it has not been possible to induce cytotoxic effector T cells against *Mls* locus antigens[4]. Recent interest in T cell responses to antigen has focused on the crucial role of MHC gene products in antigen recognition (reviewed in refs 5–8). These studies have shown that T cell responses to most conventional antigens involve recognition of both the foreign antigen and self MHC antigens. In parallel with allogeneic reactions, T cells cytotoxic to antigen-modified self cells see that antigen plus self KD molecules, while helper T cells, T cells mediating delayed type hypersensitivity and T cells proliferating *in vitro* to soluble antigens recognise the antigen in association with I region gene products. Thus,

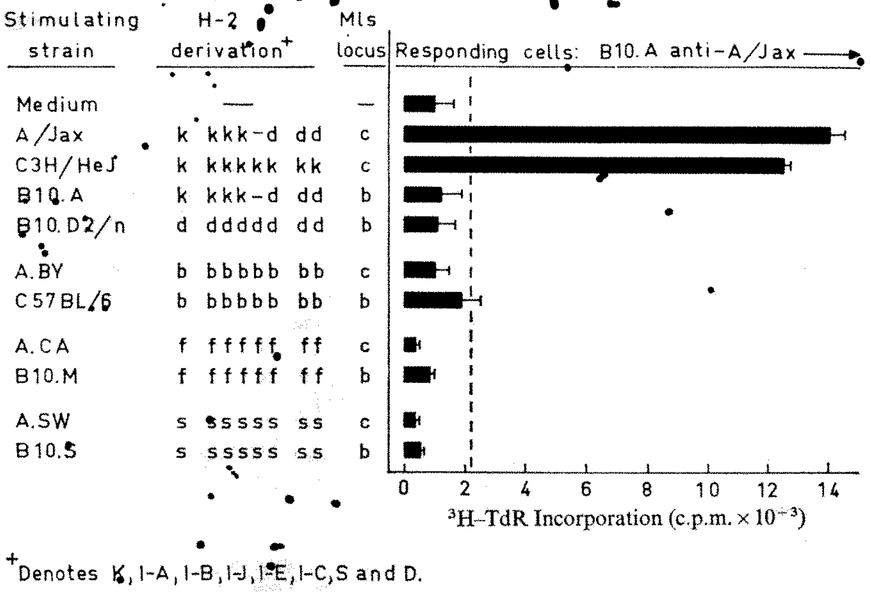

Fig. 1 Secondary stimulation of B10.A T lymphocytes primed *in vitro* with X-irradiated A/Jax spleen cells by a panel of spleen cells. The responding B10.A T cell population for primary MLC was prepared by the passage of whole spleen cell suspensions whose erythrocytes had been lysed with 0.84% NH_4Cl through Ig-anti-Ig glass bead columns, according to the protocol of Wigzell *et al.*[15]. Primary MLC were performed in tissue culture flasks (No. 3013, Falcon Plastics) and consisted of 30×10^6 responding T cells cultured with an equal number of X-irradiated (2000 R) stimulating cells in 12 ml of EHAA medium supplemented with 0.5% normal mouse serum[10,16]. The reacting T lymphocytes from the primary MLC were separated as T blast cells from the non-reacting cells using 1*g* velocity sedimentation gradients as described elsewhere[10]. 7.5×10^4 T cell blasts (> 95% blasts) were dispensed into microtitre plate wells, incubated 12 h, then restimulated with the indicated cell populations ('stimulating strain'). Secondary cultures were performed according to Peck *et al.*[10]. After 48 h of secondary MLC, the cultures were pulsed with 0.8 μCi tritiated thymidine (Radiochemical Centre, Amersham) in 20 μl for 4 h. Thymidine incorporation in harvested cells was determined by liquid scintillation counting. Data are expressed as mean c.p.m. of triplicate culture wells. Standard deviations are shown. Vertical dashed line is 2 standard deviations above the mean of incorporation in medium stimulated controls.

virtually all T cell responses involve recognition of MHC gene products, with the possible exception of responses to *Mls* locus antigens. Reactions to *Mls* locus antigens, however, are normally tested between MHC identical strains of mice, so responses to *Mls* locus antigens may also involve recognition of self MHC antigens, probably encoded in the I region[7]. Alternatively, the *Mls* locus might represent I region gene duplications translocated to another chromosome[3,9]. The present experiments were designed to test these ideas. We report that T cell responses to *Mls* locus antigens involve recognition of the products of two gene clusters. One gene cluster is clearly self *MHC* genes, probably within the I region, while the second is almost certainly the genes of the *Mls* locus. Thus, virtually all T cell responses to non-MHC antigens involve specific recognition of self-MHC antigens in association with another antigenic determinant.

We have isolated T cell blasts from primary MLC reactions between *H-2* identical, *Mls* locus differing strains, and measured their secondary *in vitro* proliferative response to fresh stimulating cells from strains sharing either MHC antigens, *Mls* locus antigens, or both with the original stimulating strain[10]. This technique facilitates study of reactions to *Mls* locus antigens in the presence of MHC antigen differences, since the selected blast cells lack reactivity to MHC antigens, at least during the time in which they are studied (48 h).

Two such experiments are presented. The first (Fig. 1) involved blast cells isolated from the reaction B10.A anti-A, and tested with a variety of strains congenic with A but differing in the MHC. It is clear that secondary reactions to *Mls* locus antigens require that the stimulating cell share *MHC* region genes with the original stimulating strain. Sharing of the rest of the genetic background is not sufficient to give a response. Since C3H/HeJ cells induced reactivation, sharing MHC genes to the left of the I-C sub-region seems to be sufficient. Sharing of *Mls* locus genes with the original stimulating strain is apparently also required for this response, but not sufficient.

A second experiment was designed to determine which portion of the MHC was involved in secondary T cell responses to *Mls* locus antigens (Fig. 2). In this instance, purified T cell blasts from the reaction of B10.BR to

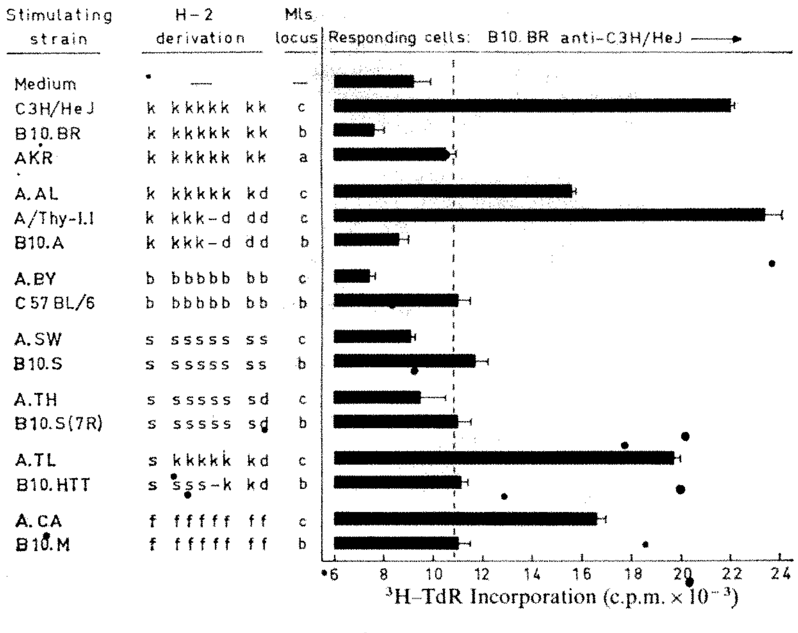

Fig. 2 *H-2* I region recognition in secondary MLC responses of B10.BR T lymphocytes primed *in vitro* with X-irradiated C3H/HeJ spleen cells towards a panel of test cells carrying various genetic differences. Primary and secondary MLC carried out as for Fig. 1.

C3H/HeJ were used. C3H/HeJ and all A congenic mice share an Mls locus antigen (Mls^C), allowing us to test the A congenic mice for secondary stimulatory activity. B10 congenic strains were used as *Mls* negative controls for any reaction to MHC differences. The results confirm the requirement for sharing MHC region genes with the original stimulating strain. Furthermore, the reactions against A.TL and A/Thy-1.1 cells demonstrate that genes mapping between K and I-C are sufficient for stimulation to occur. These experiments do not rule out the possibility of other MHC genes also being sufficient to give stimulation in this system, but both experiments demonstrate an absolute requirement for sharing of MHC genes, since the congenic mice differ only at the MHC region.

These data strongly support the notion that T cell recognition of non-MHC antigens always involves recognition of self MHC gene products. Other non-MHC cell surface antigens have been shown to behave in a similar manner. The male antigen[11] and non-H-2 transplantation antigens[12] both induce killer T cells which recognise both the antigen and KD determinants. The *Mls* locus antigens are unique, however, in being the only non-*H-2* antigens which induce a strong primary proliferative, non-cytotoxic T cell response; our data suggests they do so in association with I region gene products. Antigens with the characteristics of Mls antigens all map to a single locus, whereas there are a wide variety of non-*H-2* loci encoding antigens that give rise to cytotoxic effector cells[11,12], so this uniqueness may, in part, account for the apparently high frequency of *Mls* reactive cells.

These experiments render very unlikely the hypothesis that *Mls* locus products resemble I region gene products, since *Mls* locus antigens cannot, by themselves, induce T cell proliferation, but must be associated with an I region gene product to do so. Other differences between I region gene products and *Mls* locus antigens emerge from studies of T–B cell collaboration, where I region identity is required for effective cooperation[13] while *Mls* locus identity is not[14].

Finally, we believe that this system can be applied to the mapping of I region genes. A possible illustration of this is the finding that B10.A anti-A cells do not respond to A.CA, whereas B10.BR anti-C3H cells do respond to A.CA. This reaction pattern does not correspond to any known I region antigen, and thus may point to a new I region determinant. Further studies will be aimed at defining these unexpected cross-reactions.

Density-dependent phosphorylation of a specific protein in cultured cells

THE phosphorylation–dephosphorylation reactions that regulate the biological activities of many proteins are sensitive to changes in physiological conditions[1]. Hormones regulate the phosphorylation of both membrane-bound[2] and cytosolic proteins[3,4], while the phosphorylation of histone[5] and non-histone chromosomal proteins[6] changes during different phases of the cell cycle. The cellular density of mammalian cells grown in culture can affect biological properties such as cell growth[7], locomotion[8], transport[9] and enzyme activity[10,11]. We have examined the phosphorylation of endogenous proteins in cultured mammalian cells at different cellular densities as a means of determining whether cell–cell interactions might affect protein phosphorylation. We report here that the phosphorylability of a specific protein present in several diverse cell lines exhibits density-dependence.

Cell lines designated Balb 3T3 and SV3T3 originated from the Balb A_{31} and SVT_2 lines, respectively, established by George Todaro (NIH); T3 schwannoma originated from RN_2 lines established by S. E. Pfeiffer (University of Connecticut); AFH, an amelanotic variant of B16 melanoma lines, was obtained from J. J. Sauk Jr (University of Minnesota); the SF human diploid fibroblasts were secondary cultures derived in our laboratory.

AFH melanoma cells, T3 schwannoma and SV3T3 fibroblasts do not exhibit density-dependent inhibition of growth, and grow to high densities ($> 10^7$ cells per 100-mm plate). These cell lines were plated at both low and high densities and extracts were prepared 24–48 h after plating. The extracts were incubated with γ-^{32}P-ATP, and the ^{32}P-labelled proteins were separated by sodium dodecyl sulphate (SDS) polyacrylamide slab gel electrophoresis. A protein of molecular weight 110,000 (determined by comparison with molecular weight standards) was heavily phosphorylated in extracts from cells which had been plated at a high cell density, but was only slightly phosphorylated in extracts from low density cells (Fig. 1*a–c*). The *in vitro* phosphorylation of no other protein consistently changed as a function of increased cell density in the cell survey described here. One possible explanation for the increased phosphorylability of this protein in extracts from high density cells could be an increased concentration of this substrate protein. But when cell extracts are incubated with γ-^{32}P-ATP, only sites available for phosphorylation (that is, which have not been phosphorylated in the intact cell) incorporate ^{32}P. Thus, another explanation could be an altered regulation of the phosphorylation of the protein *in vivo*.

In addition to comparing the phosphorylation of extracts from cells which had been plated initially at high and low densities, we have also examined extracts from cells which were plated at low density and then grown to high density. Once again, the phosphorylation of this single protein was higher in the extracts from high density cells than from the low density cells (Fig. 1*d*). We conclude that the phosphorylability of this protein increases when the density of cells on a plate is high, and does not depend on the experimental manipulations used to achieve high cellular density. We have called this protein density-dependent phosphoprotein (DDP).

The effect of cellular density on DDP phosphorylation was also examined in two normal cell lines which exhibit density-dependent growth inhibition. SF, a line of human diploid fibroblasts which grows to a high density (10^7 cells per 100-mm plate) but then becomes quiescent, also showed a greater extent of DDP phosphorylation at high density than at low density (Fig. 1*e*). Balb 3T3 mouse fibroblasts normally grow to a low saturation density of about 10^6 cells per 100-mm plate. These 3T3 cells showed minimal DDP phosphorylation in extracts from both confluent cultures and sparsely populated cultures (Fig. 1*f*). Serum-stimulated (40 % serum) 3T3 cells,

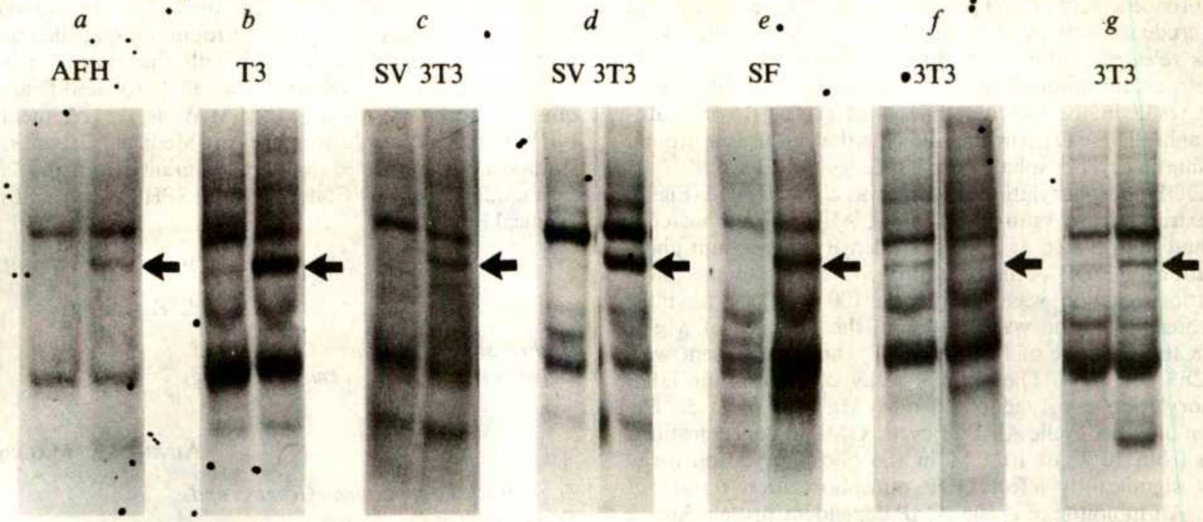

Fig. 1 Autoradiograph of ^{32}P-labelled proteins from mammalian cell lines at low and high density. Various mammalian cell types (*a–c*, *e*) were plated at either low density (10^4–10^5 cells per 100-mm plate) or high density (10^6–10^7 cells per plate) and grown for 24–48 h. The culture media for cells were: DMEM and 10% foetal calf serum for murine SV3T3, Balb 3T3 and human diploid fibroblasts; DMEM and 10% calf serum for rat T3 schwannoma; and RPMI 1640, 10% foetal calf serum and 10% tryptone for murine AFH melanoma. SV3T3 cells (*d*) were plated on 100-mm plates at low density (10^5 cells per plate) and grown to high density (10^6–10^7 cells per plate). Extracts from low density cells were prepared 8 h after plating and those from high density cells 72 h after plating. To obtain sufficient protein from sparse cultures, Balb 3T3 cells were grown in roller bottles. Extracts were prepared from low density cells (before cell contact) 4 d after seeding 100 ml of medium with 2×10^6 cells; high density cell extracts were prepared 8 d after seeding (*f*). In other experiments, Balb 3T3 cells were first grown to confluence (10^6 cells per plate) on 100-mm plates; medium was then removed and replaced with DMEM and 40% foetal calf serum, and growth continued for 48 h until a high density (4×10^6 cells per plate) was reached. Extracts were prepared from low density cells and from these high density cells (*g*). In all experiments, cells were grown at 37 °C and exposed to a humidified atmosphere of 5% CO_2. Samples were prepared by rinsing cells with 0.32 M sucrose, and disrupting the cells by sonication. Protein concentrations were determined by the method of Lowry *et al.*[12]. The crude sonicates were assayed for endogenous phosphorylation as described by Malkinson *et al.*[13]. The 100-μl reaction mixture contained 70–90 μg of protein, 50 mM (*N*-morpholino) ethanesulphonic acid (MES) *p*H 6.5, 10 mM $MgCl_2$, and 1.0–1.5 μM γ-^{32}P-ATP (5-20 Ci mmol^{-1}). After incubation for 3 min at 30 °C the reaction was terminated with an SDS-dithiothreitol 'stop solution', and the tubes were boiled for 2 min. ^{32}P-labelled proteins were separated by SDS–polyacrylamide slab gel electrophoresis[14] and autoradiographs of the dried gels were prepared. Each cell line is represented by a pair of autoradiographs. In each pair, the left autoradiograph was obtained from extracts of low density cells and the right autoradiograph from extracts of high density cells. The arrow indicates the position of DDP on each autoradiograph.

however, grew to densities of 4×10^6 cells per 100-mm plate, and more DDP phosphorylation occurred using extracts from these high density cells than with extracts from sparse plates (Fig. 1*g*). These experiments with growth-regulated human and mouse fibroblasts indicate that increased DDP phosphorylability also occurs in normal cells after growth to a sufficiently high cellular density.

The following experiment illustrates the reversibility of this density-dependent phosphorylation. SV3T3 cells were plated at a low density (10^5 cells per 100-mm plate). At various times during growth, the plates were scored for cell contact, the number of cells per plate was determined, and cell extracts containing equal amounts of protein were phosphorylated (Fig. 2). DDP phosphorylation was minimal when cells were sparse (before cell contact). When 100% of the cells had established cell contact (10^6 cells per plate), DDP phosphorylation began to increase. When the highest density was reached (10^7 cells per plate), DDP phosphorylation was 8–15 times higher than in sparsely populated plates. When these high density cells were diluted and replated at a low density, the absence of cell–cell contacts was associated with a decreased phosphorylability of DDP. When the cell number exceeded 10^6 cells per plate, DDP phosphorylation again increased.

When endogenously phosphorylated proteins from high density AFH or SV3T3 cells were incubated with pronase (30 μg ml^{-1}) at 30 °C for 15 min before the addition of SDS, DDP and all other phosphorylated bands were absent from the autoradiographs. Neither RNase nor phospholipase C had any effect on the phosphorylated bands. Boiling the homogenates before incubation with γ-^{32}P-ATP also abolished all bands from the autoradiographs. Incubation of endogenously phosphorylated proteins with a partially purified preparation of liver phosphoprotein phosphatase (supplied by J. S. Bishop)

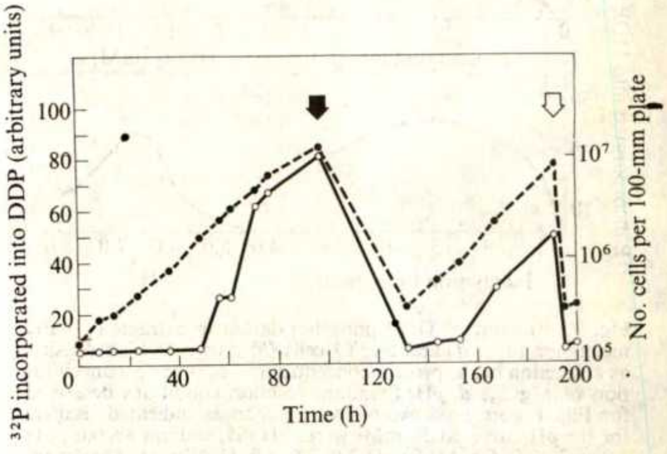

Fig. 2 Amount of DDP phosphorylation in extracts from SV3T3 cells grown to different cell densities. SV3T3 cells were plated at 10^5 cells per 100-mm plate and the medium was changed at 72 h. At the indicated times, cells were removed with 0.05% trypsin and counted. This treatment with trypsin did not affect DDP phosphorylation. Duplicate plates were prepared and assayed for endogenous phosphorylation as described, using 67 μg of protein per assay. When cells had grown to a density of 10^7 cells per plate (indicated by closed arrow), the cells were removed with trypsin, diluted in fresh medium, replated at 10^5 cells per plate and grown again to a high density. At 8×10^6 cells per plate (indicated by open arrow) cells were removed, diluted and replated at 3×10^5 cells per plate. At various intervals the cell number was determined, and extracts were phosphorylated. The amount of ^{32}P incorporated into DDP was determined by scanning the autoradiographs with an Ortec 4310 microdensitometer. The peak height of the optical density is expressed as arbitrary units of ^{32}P incorporated[15]. Cell number (●) and DDP phosphorylation (○) are shown.

reduced DDP phosphorylation on the autoradiograph. When a trichloroacetic acid (TCA) precipitate of ^{32}P-labelled proteins from a crude sonicate was incubated at 37 °C with dilute alkali, ^{32}P was released within 15 h and no phosphorylated bands were seen on an autoradiograph. Incubation with dilute acid did not result in the loss of ^{32}P-labelled proteins from autoradiographs. These experiments indicate that DDP is a protein containing an acyl phosphate ester bond.

The DDP phosphorylation reaction was characterised (Fig. 3) using extracts from both SV3T3 and AFH melanoma cells which had been plated at a high cell density. Maximum phosphorylation of DDP occurred within 3–5 min, and the phosphorylation reaction was linear from 100 to 1,000 μg ml^{-1} DDP phosphorylation was greatest in the presence of Mg^{2+}, slight in the presence of Mn^{2+} or Co^{2+}, and was absent with either Zn^{2+} or Ca^{2+}. The optimal assay conditions for DDP phosphorylation consisted of 10 mM Mg^{2+} at *p*H 6.5. The inclusion of either cyclic AMP or cyclic GMP at concentrations ranging from 10^{-11} to 10^{-4} M in the phosphorylation assay did not significantly affect DDP phosphorylation (data not shown). An inhibitor of cyclic AMP-dependent protein kinase enzymes, isolated from rabbit skeletal muscle[16], caused no inhibition of DDP phosphorylation. Thus, in our assay conditions, the kinase catalysing DDP phosphorylation is independent of cyclic nucleotides. Homogenates from high density cells were fractionated by differential centrifugation into soluble and particulate fractions and the endogenous phosphorylation assay was performed with each subcellular fraction. DDP phosphorylation was observed only with the 100,000*g* supernatant, suggesting that neither DDP nor the kinase enzyme which catalyses its phosphorylation are tightly membrane-bound.

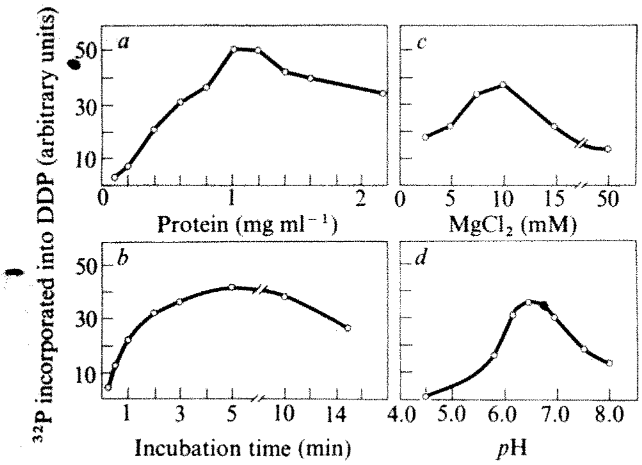

Fig. 3 Amount of DDP phosphorylation in extracts of AFH melanoma (*a*, *c*, *d*) and SV3T3 cells (*b*) grown to high density, as a function of: *a*, protein concentration; *b*, time; *c*, concentration of $MgCl_2$; *d*, *p*H. Standard reaction conditions described for Fig. 1 were used except for the changes indicated. Buffers for the *p*H curve, at 50 mM, were: *p*H 4.5, sodium acetate; *p*H 5.8, 6.2, 6.5, 6.8, MES; *p*H 7.0, 7.5, 8.0, HEPES (*N*-2-hydroxyethylpiperazine-*N*-2-ethane-sulphonic acid.

Differences in phosphate metabolism have been found between 3T3 and SV3T3 cells, and between high and low density suspensions of 3T3 cells[9,17]. It is unlikely that increased DDP phosphorylation at high density is related to these changes in phosphate metabolism, for DDP is the only protein whose phosphorylation is consistently affected by density. There are several enzymes[18] and contractile proteins[19] of a monomer molecular weight corresponding to DDP, but it is premature to speculate on the identity of this protein. It is interesting that a phosphorylated protein corresponding in molecular weight to DDP has been observed in foetal rat tissues, but not in adult tissues (A.M.M. and C. E. McSwigan, in preparation). In the cellular slime mould *Dictyostelium discoideum*, the number of freely phosphorylable sites per cell decreased at the onset of cell aggregation[20]. Because many membrane properties change as a function of cellular density[21], the biological activity of DDP may eventually be found among the contractile proteins or enzymes associated with the plasma membrane.

Connectivity of the monoamine-containing neurones in central nervous system of leech

THE functional properties of neurones which contain biogenic amines are usually proposed from the results of studies involving ablation or pharmacological intervention[1]. Monoamine (MA) neurones are seldom identifiable *in vivo*, which impedes direct investigations of their functions. The central nervous ganglia of leeches are comprised of about 350 neurones, nine of which contain amines as their putative neurotransmitters. These MA neurones are vitally and selectively stained by Neutral Red dye[2], a procedure potentially facilitating intracellular studies of this population of biochemically related cells. We report here the electrophysiological properties of the red-staining neurones within the central nervous system (CNS) of the leech.

Chains of five to eight segmental ganglia were dissected from horse leeches, *Haemopis marmorata* (Say), and their MA cells were stained by 0.01% (w/v) Neutral Red in leech saline[3] for about 30 min. Nine widely scattered neurones stain within the three anterior-most ganglia, while seven stain within each of the 18 posterior ganglia (Fig. 1). These neurones included the two Retzius cells (RZ, 50–65 μm), two pairs of lateral cells, one pair ventral (VL), the other dorsal (DL), and a posterior, unpaired medial cell (M). An extra pair of MA cells (E) was seen within each of the three anterior ganglia. These seven small (15–20 μm) intraganglionic neurones shared histochemical properties with the RZ (refs 4, 5), which contain the indolealkylamine, serotonin (5-hydroxytryptamine, 5-HT)[6]. The interconnected 21 segmental ganglia innervate the body by means of paired lateral roots. A stainable neurosoma is situated in each anterior root, and this pair of anterior root cells (AR) probably contains the catecholamine, dopamine[2]. The large RZ send axons to the periphery[4,7], while the small MA cells appear to restrict their connections to the CNS.

Stained cells were impaled with glass micropipettes (4 M potassium acetate) with tip resistances of 20–50 MΩ. Membrane potentials and impulse activities were controlled with currents injected through the recording electrodes by means of balanced bridge circuits. Potentials were recorded on tape (FM, HP 3960) and permanent records were usually produced by playback at ¼ speed into an oscillographic recorder (HP 7404). Such speed reduction avoids attenuation by the oscillograph of the high frequency components of the action potentials.

Stained RZ cells have resting potentials (40–60 mV) and non-invading action potentials (30–55 mV) indistinguishable from those in unstained preparations[2]. Furthermore, the stained pair of RZ remain coupled by an efficacious electrotonic junction. The small MA cells have small action potentials (usually 5–15 mV) which do not actively invade their somata. We recorded simultaneously from a Retzius cell and each of the small ganglionic MA neurones, and representative results are shown in Figs 2 and 4. The impaled MA neurones usually have tonic impulse activities and post-synaptic potentials, and frequently produce bursts of impulses. These bursts usually occur with slowly rising depolarisations of 5–15 mV. As Fig. 2*a* shows, the bursts in the RZ and the small cell usually occur in temporal register, suggesting that they receive a common excitatory input[8]. Cross correlograms of the time intervals between the depolarisations of the MA cell pairs support the suggested pattern of a common excitor. We see this pattern of nearly synchronous depolarisations and impulse bursts between RZ and both DL and M (Fig. 2*a*) as well as VL and E (not shown here). To map more completely the responses of the MA cell population, we impaled and recorded simultaneously from three pairs of small, bilaterally homologous cells—VL–VL, DL–DL and E–E. As Fig. 2*b* (VL–VL) shows, these cell pairs also undergo nearly synchronous depolarisations which generate impulse bursts. We have recorded from pairs of non-homologous small cells and found a similar pattern of common excitatory bursts by the following pairs: VL–DL, VL–M, E–M and VL–E (Fig. 2*c*).

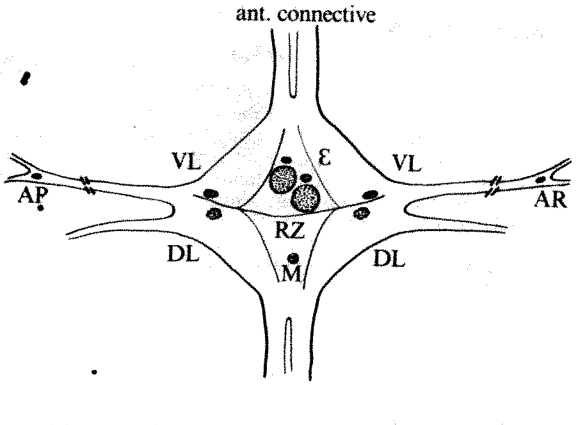

Fig. 1 Diagram of the ventral aspect of a leech segmental ganglion showing the positions of the MA-containing neurones which are stained by Neutral Red dye.

Thus the entire population of MA neurones shares an excitatory input and often fires synchronous bursts of impulses. The addition of 20 mM Mg^{2+}, which blocks chemical synaptic transmission in leeches[9], abolishes these depolarisations and bursts. In view of this finding, we initiated pharmacological experiments on the chemical synaptic nature of the excitatory depolarisations. Serotonin (10^{-5} M) neither enhances nor induces bursts by MA neurones; 5-HT (the putative transmitter of these cells) hyperpolarises RZ, abolishing all spontaneous impulse activity. Acetylcholine (ACh) is a candidate transmitter for it depolarises and excites RZ into impulse activity[10]. Atropine is a competitive inhibitor of ACh at muscarinic receptor sites and it effectively blocks the slow depolarisations and impulses bursts by RZ (Fig. 3). The depolarised bursts return after the atropine is washed from the preparation. Furthermore, the anticholinesterase eserine

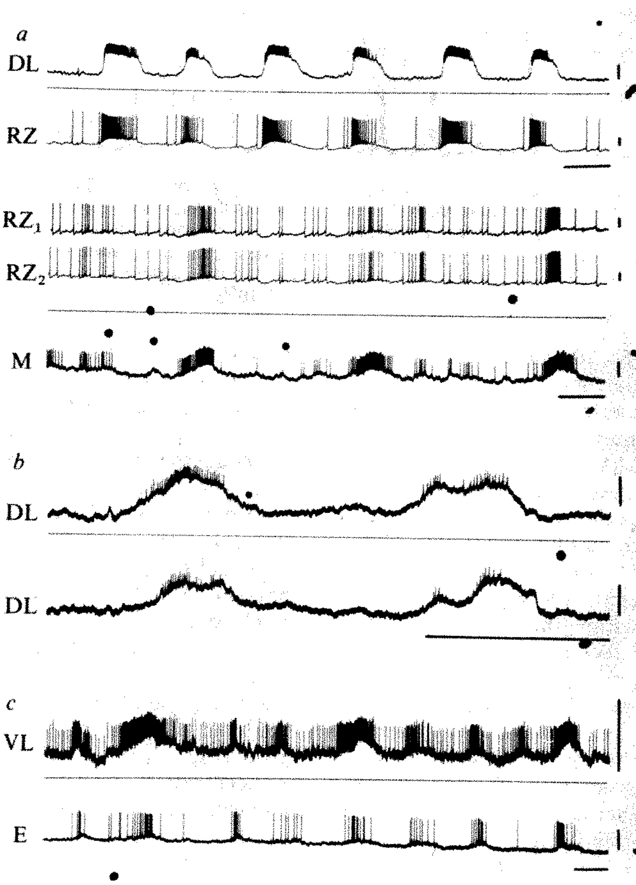

Fig. 2 Intracellular recordings of the spontaneous activity in the red-stained MA neurones of the leech *Haemopis*. Calibrations: 10 mV, 5 s. *a*, Top panel showing the slowly rising depolarisations and the resulting impulse bursts in DL (top trace) and RZ. The lower panel shows three simultaneous recordings from the pair of RZ and an M cell. The RZ maintain perfect impulse synchrony during burst and interburst periods. M depolarises, generating bursts at similar times to the RZ; however, M impulses do not match those of RZ in a 1 : 1 fashion. *b*, Slow depolarisations of both DL cells generate impulse bursts. The membranes of both cells show similar slow potential changes, but the action potentials are not 1 : 1. *c*, Recordings of the depolarisations and action potential bursts in VL (top trace) and E. In this record the impulse frequency of VL is higher than that of E. The magnitudes of the depolarisations appear to differ because of the different gains of each trace.

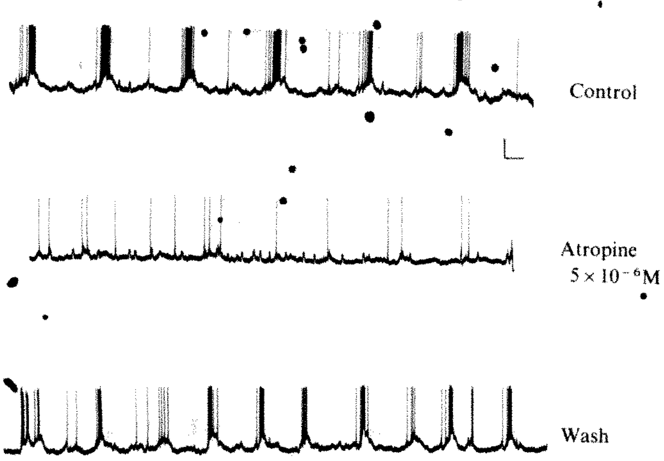

Fig. 3 RZ activity in a stained, bursting preparation. The top panel is a control with depolarisations and bursts at a period of 20–25 s. Atropine blocks the slow depolarisations, but not other unitary excitatory postsynaptic potentials (middle). After washing (bottom), depolarising bursts return but at a period of about 12 s. Calibrations: 10 mV, 5 s.

(5×10^{-4} M) increases both the amplitude and duration of the spontaneous depolarisations seen in the RZ. These eserine-enhanced depolarisations can also be blocked by addition of atropine. We always saw bursts in the small MA cells whenever depolarisations occurred in RZ, and as these depolarisations seem to be mediated by a common excitor, most pharmacological experiments were done with the larger, more accessible RZ. We have verified the effects of atropine on both VL and M cells. Therefore, the central synaptic input which depolarises the MA neurones within the leech ganglion is probably cholinergic.

We passed currents into RZ while monitoring the effects on small MA cells in order to determine the nature of any interconnections among the aminergic population. Inward current directly hyperpolarises RZ and also hyperpolarises the small cells to a lesser degree (Fig. 4*a*). These d.c. potential shifts persist in a high concentration of Mg^{2+}, and increase monotonically with increasing currents. In one case each nA into an RZ produced a potential change of 0.38 mV in DL. Thus the RZ is coupled to each of these small cells by an ohmic junction: M and E (Fig. 4) and VL and DL (not shown). In addition, hyperpolarisation of each of these small cells will also produce a d.c. hyperpolarisation of the RZ. The RZ are coupled to one another by a low resistance pathway such that an impulse in one cell produces an electrotonic potential in the other which exceeds impulse threshold, and therefore the RZ maintain impulse synchrony (Fig. 2*a*). The small MA cells are coupled to the RZ by a higher resistance junction. Each RZ impulse can be detected within the small cell somata as an electrotonic potential of about 0.5 mV. These potentials are resistant to Mg^{2+} and have a latency of less than 1 ms. In high Mg^{2+}, a current-induced burst of RZ impulses will electrotonically depolarise a small MA cell to impulse threshold. Experiments on the homologous, small cell pairs show electrotonic coupling between E–E, DL–DL and VL–VL (Fig. 4*b*). Similarly electrotonic coupling is seen between the following pairs of small, non-homologous cells: VL–DL, VL–M and E–M (Fig. 4*c*). Hyperpolarisations are usually more effective than are depolarisations for all these MA cell junctions.

Thus all nine monoamine-containing neurones within the leech ganglion seem to be electrotonically intercoupled. Electrotonic interconnections provide a route by which positive feedback can generate bursts of impulses[11]. Such bursts are produced by the injection of currents into these MA neurones; however, anodal break stimulation (cessation of hyperpolarisation) is more effective in generating a self-sustaining burst than is depolarisation (Fig. 4*a* and *c*). These anodal break bursts can be induced both in preparations showing no spontaneous bursts, and out-of-phase with the timing of the excitor in those showing spontaneous synchronous bursting. Occasionally we can generate an anodal break burst by the MA neurones in high Mg^{2+} saline. Thus the electrotonic coupling among the MA cells is at least in part responsible for burst formation.

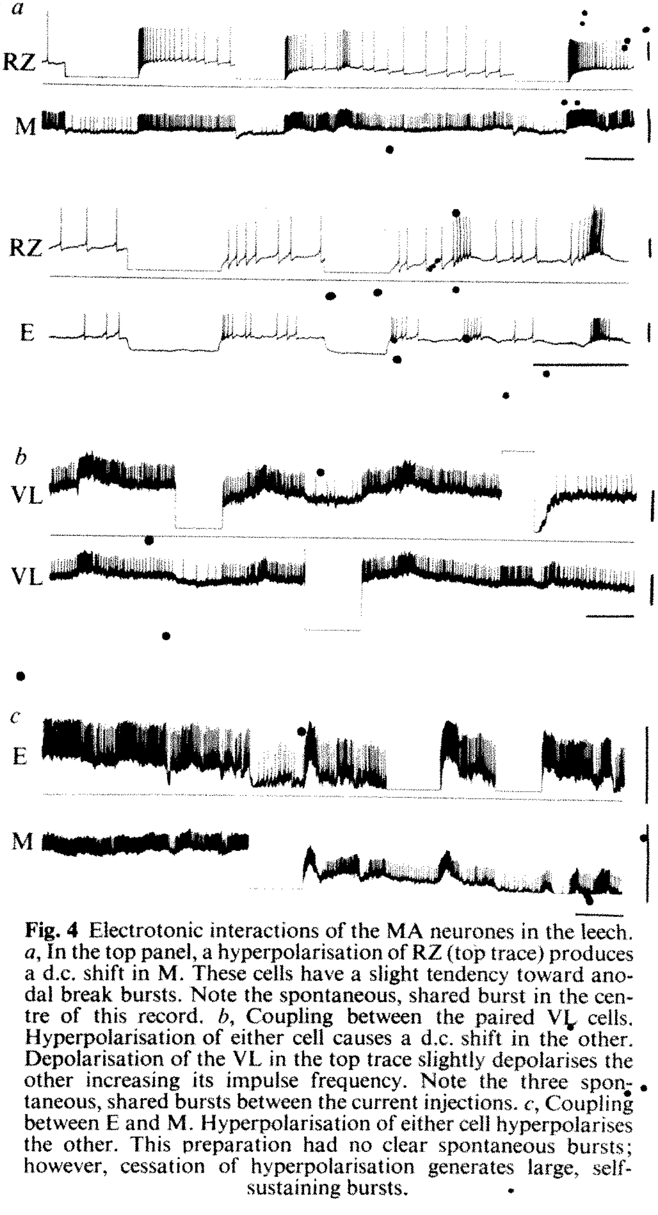

Fig. 4 Electrotonic interactions of the MA neurones in the leech. *a*, In the top panel, a hyperpolarisation of RZ (top trace) produces a d.c. shift in M. These cells have a slight tendency toward anodal break bursts. Note the spontaneous, shared burst in the centre of this record. *b*, Coupling between the paired VL cells. Hyperpolarisation of either cell causes a d.c. shift in the other. Depolarisation of the VL in the top trace slightly depolarises the other increasing its impulse frequency. Note the three spontaneous, shared bursts between the current injections. *c*, Coupling between E and M. Hyperpolarisation of either cell hyperpolarises the other. This preparation had no clear spontaneous bursts; however, cessation of hyperpolarisation generates large, self-sustaining bursts.

The intraganglionic MA cells share a common cholinergic input, and are electrotonically intercoupled. Either of these patterns of connectivity can produce bursts by the MA cells. Presumably the presence of both patterns assures a concerted impulse activity. We do not know why the monoamine-containing neurones burst in concert as their functional role is unknown, except for a peripheral function for RZ in controlling the secretion of mucus from the skin of the leech[12]. Thus, the functioning aminergic neurones in the leech are both identifiable and experimentally accessible.

Post-mortem changes implicate adenine nucleotides and pyridoxal-5′-phosphate in regulation of brain glutamate decarboxylase

GLUTAMATE decarboxylase (GAD) is the enzyme responsible for the synthesis of γ-aminobutyric acid (GABA), an important neurotransmitter in the CNS (ref. 1). Alterations in GAD activity have been implicated in epilepsy, drug-induced convulsions and neurological diseases such as Huntington's chorea and parkinsonism[2–5]. Although this enzyme has been under study for over 20 yr, little is known of the molecular mechanisms by which its activity is regulated. Recent results suggest that the degree of saturation of GAD by its cofactor, pyridoxal-5′-phosphate (pyridoxal-P), *in vivo* could be determined by a balance between the rate of dissociation of the cofactor from the enzyme brought about by glutamate and the rate of association of the cofactor with the apoenzyme, which is inhibited strongly by the nucleotides ATP and ADP (ref. 6). Thus, it seemed likely that degree of saturation of GAD by pyridoxal-P *in vivo* might be low and might increase as a consequence of post-mortem changes in the levels of ATP and ADP. Additional activation *in vitro* during preparative steps might also occur because nucleotide levels would be reduced during homogenisation. Data presented here confirm these expectations and implicate the adenine nucleotides and pyridoxal-P in the regulation of GABA synthesis.

The percentage saturation of GAD by pyridoxal-P is defined here as the activity of GAD measured in the absence of added pyridoxal-P as a percentage of the activity measured in the presence of saturating levels of the cofactor (100 μM). This approach is possible because the cofactor is tightly bound to the active site in the absence of glutamate and cannot be removed by either dialysis or Sephadex column chromatography[6,7]. As it has been shown that there is a time-dependent inactivation of the enzyme in the absence of pyridoxal-P and in the presence of high concentrations of glutamate, GAD was incubated for only 5 min with 1 mM glutamate. We estimate that the loss in activity is no more than about 5% in the absence of pyridoxal-P in these conditions. When ATP was added to the homogenate to prevent the association of pyridoxal-P with GAD, we used a concentration of ATP fivefold greater than the concentration of ATP required for maximal inhibition of activation by low levels of pyridoxal-P in order to overcome loss of ATP by hydrolysis[6].

If brain extracts were prepared in the conventional manner by decapitating the animal, dissecting the brain at room temperature and homogenising in the absence of ATP, we found that the enzyme was 84% saturated by pyridoxal-P (Table 1). If ATP was added to the homogenising medium, however, the degree of saturation fell significantly to 60% ($P < 0.001$). The difference between these values (25% saturation) represents the *in vitro* activation of the enzyme. Similar significant decreases in the percentage saturation were also observed when ATP was included during the homogenisation of brain samples obtained by freeze-blowing[8] or from heads decapitated into liquid nitrogen (Table 1). To determine whether this *in vitro* activation could be attributed to the binding of endogenous cofactor to the apoenzyme, the concentration of the endogenous pyridoxal-P was directly measured in $HClO_4$ homogenates using tyrosin apodecarboxylase[9]. The results confirmed that there was sufficient pyridoxal-P to account for this activation (0.5–1.0 μM). Further evidence of an *in vitro* activation of the enzyme was provided by the observation that the degree of saturation of the enzyme was significantly lower (65%, $P < 0.01$) when 2% rather than 10% homogenates (ratio of tissue weight to total volume) of conventionally dissected brains were prepared (without ATP). Thus, there seems to be a significant increase in the degree of saturation of the enzyme by pyridoxal-P during preparative procedures *in vitro*.

Table 1 Effects of methods of killing and conditions of homogenisation on the percentage saturation of brain GAD

Method	GAD activity (nmol per mg protein per 5 min) Homogenised without ATP No pyridoxal-P	100 µM pyridoxal-P	Saturation (%)	*n*	Homogenised with 5 mM ATP No pyridoxal-P	100 µM pyridoxal-P	Saturation (%)	*n*
a, Decapitated and dissected at room temperature	6.3±0.2	7.5±0.2	84±5	4	5.0±0.2‡	8.3±0.4	60±2	4
b, Decapitated into liquid nitrogen	6.1±0.4	7.9±0.2	77±3	4	3.2±0.4	7.3±0.5	43±3	5
c, Freeze-blown	4.0±0.3*	6.7±0.2†	59±2	3	2.6±0.1	7.5±0.3§	35±2	4

Saturation was determined by dividing activity obtained in the absence of added pyridoxal-P by total activity obtained in the presence of saturating pyridoxal-P (100 µM). Whole brain from male Sprague–Dawley rats (200–250 g) was removed by three different methods. In (*a*) rats were decapitated and the brains were dissected out at room temperature. Each was then cut along the midline and half was homogenised in about 9 volumes of 5 mM ATP (*p*H 6.5); the rest was homogenised in a similar volume of ice-cold deaerated distilled H_2O. Homogenisation was performed within 2 min of decapitation and samples were immediately centrifuged at 16,000*g* for 30 min at 4 °C. The supernatant was removed and diluted 1:1 with buffer to give 100 mM imidazole-acetate, *p*H 6.5, and 5 mM mercaptoethanol. Two ml of each diluted supernatant was then passed over a column of Sephadex G-25 (bed volume 70 ml) at a flow rate of approximately 2 ml per min to remove ATP, endogenous glutamate, pyridoxal-P, and other low molecular weight compounds. The column had been pre-equilibrated with buffer at the same concentration and kept in the cold. Five ml of column effluent was collected and used for analysis of GAD activity both in the presence and absence of pyridoxal-P (100 µM). The procedure used for the enzymatic assay was similar to that previously reported[17] except that the enzyme was incubated for only 5 min and with only 1 mM glutamate. We have previously shown a one-to-one correspondence in the production of CO_2 and GABA from U-^{14}C-glutamate[7]. In (*b*) rats were decapitated and the heads were frozen in liquid N_2. After dissection at 0–2 °C each brain was ground to a fine powder and divided into two equal fractions for homogenisation and further treatment as presented in method (*a*). In (*c*), brain samples were rapidly removed by freeze-blowing, each was ground to a fine powder and divided into two equal fractions for homogenisation and further treatment as for (*a*). In all cases samples with saturating pyridoxal-P (100 µM) were significantly different from paired samples without pyridoxal-P ($P < 0.02$). Comparing corresponding samples analysed in the absence of pyridoxal-P, significantly lower values were obtained in all cases when the samples were homogenised in 5 mM ATP ($P < 0.01$). A similar comparison of samples analysed with saturating pyridoxal-P showed a significant difference only in the freeze-blow method ($P < 0.05$). All values are mean ±s.e.m.

*Significantly different from similarly treated samples in (*a*) and (*b*), ($P < 0.02$).

§Significantly different from similarly treated samples in (*a*), ($P < 0.05$).

Post-mortem activation of GAD in the intact brain can be seen by comparing the results obtained with ATP-treated homogenates of brains collected by freeze-blowing and the results obtained with similar homogenates of brains dissected at room temperature (Table 1). The freeze-blowing technique removes brain samples and freezes them to liquid nitrogen temperatures within 1 s thereby preventing post-mortem changes in the levels of adenine nucleotides and other energy metabolites[8]. We found that the percentage saturation of the enzyme in homogenates of brain dissected at room temperature (60%) was significantly greater than the percentage saturation in homogenates of freeze-blown brains (34%, $P < 0.001$). The difference between these values (26%) is the post-mortem activation in the intact brain. The activation resulted in an almost twofold increase in the amount of holoenzyme present in the homogenates as indicated by the enzyme activity measured in the absence of pyridoxal-P. Decapitation into liquid nitrogen also reduces the post-mortem activation as shown by the finding that the percentage saturation in ATP-treated homogenates from animals in this group (43%) was significantly lower than the value obtained with similar homogenates from brains dissected at room temperature ($P < 0.001$). A significant post-mortem activation was also observed with samples homogenised in the absence of ATP. In this case, the degree of saturation of the enzyme in brains dissected at room temperature (84%) was significantly greater than the degree of saturation in samples from freeze-blown brains (59%, $P < 0.001$). Since freeze-blowing prevents the rapid post-mortem hydrolysis of ATP which accompanies anoxia[8], the relatively low degree of saturation in these freeze-blown samples could be attributed to the presence of sufficient endogenous ATP which reduces substantially the amount of binding of pyridoxal-P to the apoenzyme. A similar low degree of saturation was not observed in samples from animals decapitated into liquid nitrogen. It has been shown, however, that marked post-mortem changes in the levels of brain metabolites including a 40% reduction in the brain level of ATP occur during freezing by this method[8]. Thus, there is apparently an insufficient amount of endogenous nucleotides present in these homogenates to prevent the activation of GAD.

Our results demonstrate that brain GAD undergoes both a post-mortem activation by pyridoxal-P in the intact brain and a further activation *in vitro* during preparative procedures. The high degree of saturation (84%) observed in homogenates of brains dissected at room temperature are attributable to these effects. When both types of activation were minimised by homogenising freeze-blown brain samples in 5 mM ATP, the enzyme was only 35% saturated. Clearly, this represents an average for many brain regions and compartments and the actual degree of saturation in any particular compartment may differ significantly from this value. The results do indicate, however, that brain GAD is, in general, only partially saturated with pyridoxal-P. Because of the two types of activation reported here and the glutamate-promoted, time-dependent inactivation of the enzyme[17], previously reported estimations of the degree of saturation of the enzyme by pyridoxal-P *in vivo* may not reflect the actual values but instead may largely be the result of the experimental conditions. These same considerations also suggest that studies dealing with alterations in the relationship between pyridoxal-P and GAD in drug-induced or pathological states may need to be reconsidered.

It has been demonstrated repeatedly that brain GABA levels increase rapidly after death[10–13]. The post-mortem activation of GAD in the intact brain described here may be a factor contributing to the post-mortem change in GABA levels.

The post-mortem activation of GAD together with the known effects of adenine nucleotides and inorganic phosphate on the interaction between pyridoxal-P and GAD (refs 6, 14), support the idea that these compounds are involved in the mechanism controlling the rate of GABA synthesis. Although whole brain levels of ATP are quite constant under normal conditions, it is conceivable that fluctuations in ATP levels may occur in various compartments such as presynaptic endings during periods of altered physiological activity[15]. Kennedy *et al.*[16] provided strong evidence that changes in the functional state of nervous tissue result in changes in energy metabolism. Such changes might alter the degree of saturation of GAD by pyridoxal-P and thereby mediate changes in the rate of GABA synthesis. On the other hand, the interactions between GAD, pyridoxal-P, and the adenine or other nucleotides may merely set the general level of activity of the enzyme and regulation may be accomplished by other, as yet unknown, factors.

We thank Dr R. L. Veech for providing a freeze-blowing device and Mr R. Slovis for technical assistance.

Effects of dietary choline on nicotinic acetylcholine receptors in brain

THE administration of choline by injection[1] or diet[2] increases the concentration of acetylcholine (ACh) in the brain. Choline also increases the activity of tyrosine hydroxylase[3] (TOH) in dopaminergic neurones of the caudate nucleus that receive cholinergic inputs. This response can be blocked by atropine, indicating that it is due to the post-synaptic action of ACh. The post-synaptic alteration of TOH activity suggests that the level of ACh also regulates the concentration of ACh receptors (AChR). To produce large differences in brain ACh, we have studied two groups of rats, one deprived of choline and the other loaded with choline. We found high concentrations of ACh in the brain associated with increased amounts of nicotinic AChR.

Male, Sprague–Dawley rats, 60 d old (230–300 g) from five litters were assigned to either choline-deficient or choline groups using the split-litter technique. Choline-deficient animals were maintained *ad libitum* on a diet lacking choline (ICN Biochemicals) and were given distilled water to drink. The choline groups were maintained on the same diet but choline chloride 15 mg ml^{-1} (Sigma) was added to the distilled water in the drinking bottle. All animals were housed in groups of four to a cage. After 21 d, they were decapitated. The brain and hind leg muscles from each animal were processed individually to extract and quantify the receptors present. All procedures were carried out at 4 °C. Each individual tissue was homogenised in ten volumes of 0.32 M sucrose and 10 mM sodium phosphate, *p*H 7.4. The homogenate was centrifuged at 100,000*g* for 60 min. The pellet was resuspended (ten volumes of original weight) in 10 mM sodium phosphate, *p*H 7.4 and 1% Triton X-100 and shaken gently for 105 min. The homogenate was then centrifuged at 100,000*g* for 60 min. The resulting supernatants (S_2) of brain and muscle were assayed for AChR using ^{125}I-α-bungarotoxin which binds to these receptors with unparalleled affinity and specificity[4]. The nicotinic AChR from brain are similar to the AChR from muscle and electric fish in that they are located at the synapse and have similar toxin binding kinetics, solubility, isoelectric point and hydrodynamic properties[5–10]. Radioactive toxin was prepared by the solid phase lactoperoxidase method yielding a monoiodinated product (specific activity 1.2×10^4 Ci mol^{-1}) and the assay system was based on the use of small columns of CM-50 (Pharmacia) to retain excess ^{125}I-bungarotoxin while allowing receptor–toxin complexes to pass through[11]. This is the opposite principle to the DEAE filter disk assay[12]. All assays were carried out in duplicate and parallel samples were pre-incubated with a 100-fold excess of unlabelled toxin. Specific binding was taken to be the difference between the two assays with and without isotope dilution by unlabelled toxin. There was a 26% increase in the concentration of specifically bound ^{125}I-α-bungarotoxin in the brains of animals which were maintained on the choline diet when computed in proportion to protein extracted ($P < 0.001$) or wet weight ($P < 0.01$). The absolute amount of non-specific toxin binding was less than 25% in all cases and did not differ significantly between groups. No significant differences were observed in the case of AChR from muscle. The increase in brain AChR was not due to malnutrition or a non-specific effect on growth, for brain protein and brain weight were not significantly different between the two groups. The daily intake of choline by the choline group was approximately 250 mg per animal. The body weight gain throughout these experiments was not significantly different between the two groups. (See Tables 1 and 2).

Additional rats were maintained in the same conditions and the brains were sectioned into cerebral hemispheres (including olfactory bulbs), remaining forebrain, brain stem and cerebellum, to determine whether there were regional differences in the relationship of AChR to the dietary manipulation. Significant differences in the density of AChR were observed in the cerebral hemispheres (48% increase in the high choline group) and forebrain (43% increase) thus accounting for most of the whole brain differences. A slight but insignificant increase was found in the brain stem. In agreement with other reports, only minimal amounts of AChR were found in the cerebellum[13–15]. Brain weights and extracted protein did not differ between the groups for any brain section.

Thus, these studies suggest that the receptor concentration is positively related to ACh level. Because the range of choline consumption used in the two groups was within the range of variation that could occur in the human diet[2], we suggest that alteration in diet can alter brain function by controlling not only the amount of ACh released but also the density of receptors with which it may interact. This observed correlation between transmitter level and receptor density has significant implications for the relationship between cholinergic neurones and behaviour. Indeed it has been reported that a patient with tardive dyskinesia has been successfully treated with large doses of choline[16]. Although little is known about the development and functional implications of AChR in brain, ACh has long been implicated in the physiological basis of several forms of behaviour[17], including memory and learning. We are currently investigating the relationship between diet-induced changes in AChR and learning in the developing and adult rat. The possibility of altering such behaviour by dietary manipulation has profound implications.

Table 1 Effects of choline and choline-deficient diets on brain weight, body weight, whole brain protein and nicotinic AchR concentration in whole brain and muscle

Group	Brain weight (g)	Body weight (g)	Total brain protein mg (S_2 supernatant)	pmol toxin per g brain wet weight	pmol toxin per mg brain protein	pmol toxin per g muscle wet weight	pmol toxin per mg muscle protein
Choline	2.07±0.02	116±6.9	114±2.0	3.29±0.13*	0.056±0.001†	0.3549±0.04	0.0152±0.001
Deficient	2.06±0.02	128±4.7	120±5.1	2.61±0.12	0.042±0.001	0.3359±0.04	0.0138±0.002

Values are expressed as mean ±s.e.m. of 11 animals. Aliquots of supernatant were incubated with ^{125}I-α-bungarotoxin for 60 min at room temperature and then assayed. Radioactivity was determined with a Nucleus γ scintillation counter at an efficiency of 50%. Protein was determined by the method of Lowry *et al.*[18] using bovine serum albumin as a standard.

Electrophysiological distinctions between the taste and smell of amino acids in catfish

VERTEBRATES possess two principal systems, olfaction and taste, adapted to respond to peripheral chemical excitation. Olfaction in terrestrial vertebrates is the more acute chemosensory system, having lower thresholds to volatile stimuli than the gustatory thresholds to nonvolatile compounds[1,2]; thus, olfaction was termed the 'distance' sense and gustation the 'contact' sense. With fishes, however, chemical stimuli are present in the aqueous medium and it is difficult to distinguish between olfactory and gustatory stimuli or to explain the development of two chemical senses in the primitive aquatic vertebrates. Fishes exhibit important morphological distinctions between olfactory and gustatory systems both at the periphery and centrally[3], and yet, in catfish, amino acids are the most effective stimuli known for both systems[4,5]. This sensory overlap does not reflect a simple duplication of receptor function, however, as the olfactory and gustatory systems of catfish differ in amino acid sensitivity, specificity and response characteristics, which could allow for the functional separation of the chemical senses in an aquatic environment.

Channel catfish, *Ictalurus punctatus*, approximately 70–200 g, were immobilised with Flaxedil (gallamine triethiodide; 0.1 mg per 100 g body wt) and positioned in a Plexiglas container with aerated well-water containing MS 222 (tricainemethane sulphonate; 1:8,000 dilution) perfusing the gills throughout the experiments; this combination of Flaxedil and MS 222 provided for a more stable preparation than either agent alone. Stimuli dissolved in well-water, approximately *p*H 7.8, were introduced into a continuous flow of well-water directed to the maxillary barbel or olfactory capsule, and dilutions were determined by photodensitometry of dye solutions. Taste solutions were diluted at least to 60%, and olfactory stimuli at least to 25% of their applied concentrations. For the taste experiments, the eye was removed and a branch of cranial nerve VII (facial) to the maxillary barbel was exposed and placed on a Pt–Ir wire electrode and covered with mineral oil to prevent drying. To record olfactory receptor responses, a flap of tissue dorsal to the olfactory capsule was removed and a metal-filled glass capillary electrode tip plated with Pt-black[6] with a ball diameter between 15 and 25 μM was positioned between adjacent olfactory lamellae near the midline. Both gustatory and olfactory electrical activity were amplified by a conventional capacity-coupled preamplifier, passed through an averaging circuit (Sanborn Model 350–1400 amplifier operated on the a.c. linear mode) with a rise time of 1.0 s and displayed on a pen recorder. The underwater electro-olfactogram (EOG) (ref. 7), an olfactory mucosal slow potential[8], was recorded with calomel electrodes via Ringer-agar filled capillary pipettes, amplified by a direct-coupled amplifier and displayed on a pen recorder. An essential requirement for successful recording preparations was the use of freshly obtained fish. A rapid decline of olfactory and gustatory receptor sensitivity occurred with increased holding time in the laboratory[9].

Catfish olfactory and gustatory responses revealed many similarities, but were functionally distinguishable by four criteria: phasic–tonic response characteristics, amino acid thresholds, neural spike synchrony and ordering of effective amino acids. The asynchronous neural response of the maxillary

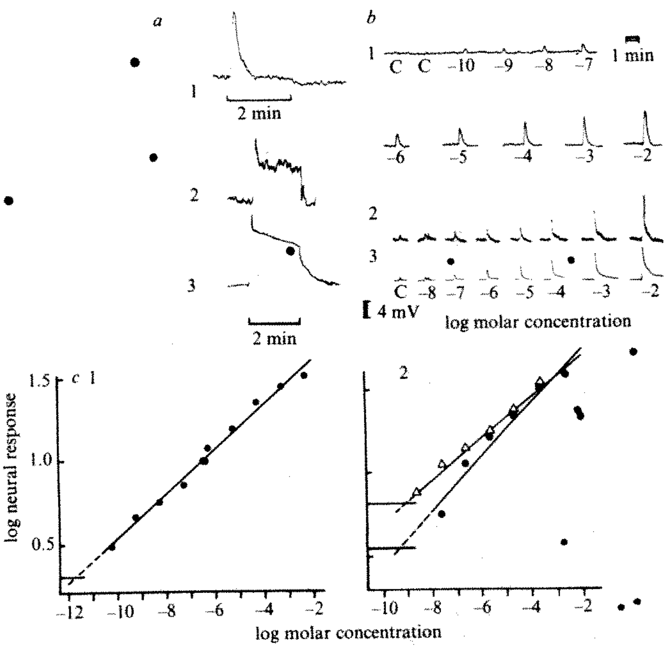

Fig. 1 *a*, Catfish taste and smell responses to a 2-min stimulation with 0.1 mM L-alanine; summated taste recording exhibits only a phasic response (1), while summated olfactory neural (2) and EOG (3) responses show both phasic and tonic components. *b*, Responses to applied concentrations of L-alanine (taste) and L-cysteine (smell); neural taste (1) and simultaneously recorded olfactory neural (2) and EOG (3) responses to applied stimulus concentrations are shown. Lack of olfactory tonic component due to short stimulus duration. *c*, Power relations[19] between chemoreceptor responses and amino acid stimulus concentrations. (1) Taste neural responses; $\log R = 0.132 \log c + 1.84$, $r = 0.99$. (2) Olfactory neural (▲) and EOG (●) responses; $\log NR = 0.125 \log c + 1.95$, $r = 0.99$; $\log \mathrm{EOG} = 0.163 \log c + 2.06$, $r = 0.98$. Taste and olfactory neural responses exhibit similar slopes (range 0.07–0.14); EOG slope is somewhat larger (range 0.14–0.29); dotted lines show interesection of linear regression lines with control responses yielding threshold values. Taste is more sensitive than smell in catfish for the compounds tested. All plotted values have been corrected for dilution and are estimates of the stimulus concentrations at the receptors; taste solutions were diluted by 0.2 log unit and olfactory solutions were diluted by 0.6 log unit as determined by photodensitometry of dye solutions. The olfactory neural response to 10^{-2} M L-cysh (b2) was omitted from the graph (*c*2) due to partial synchronisation of the neural spike activity[11,12]. The processing of this partially synchronous activity by the amplifier averaging circuit resulted in the larger than expected response amplitude, and was therefore not used in determining the olfactory neural threshold.

barbel taste nerve to an amino acid stimulus revealed a quickly adapting phasic response (Fig. 1, *a*1) with thresholds averaging $10^{-11\pm1.7}$ M (Fig. 1, *b*1, *c*1) for the more effective amino acids. The absence of the tonic component of the gustatory response was due possibly to adaptation occurring at the synapse between the taste bud cells and the innervating axon[10].

Neural and EOG recordings from olfactory neurons, neuroepithelial cells which do not form synaptic connections until the receptor cell axons reach the central nervous system in the olfactory bulb, exhibited a phasic component followed by a tonic response which remained throughout the stimulus duration (Figs 2, 3). Olfactory thresholds were less than those observed for the taste system and averaged $10^{-8.4\pm1.0}$ M (Fig. 1, *b*2, *c*2). Also, a partial synchronisation of the axonal spike activity[11] occurred with the more responsive preparations when long interstimulus intervals (> 5 min) and high concentrations ($\geqslant 10^{-4}$ M) of the more potent amino acids were utilised. Self stimulation of the olfactory organ by the EOG has been a suggested mechanism for the neural synchrony[12]. Gustatory neural activity, however, always remained asynchronous.

The difference in olfactory and gustatory thresholds is not simply a reflection of the differences in the neural recording techniques. The results with the Pt-black ball method (olfactory neural recording), which samples a smaller population of neurons than the Pt–Ir electrode (gustatory recording), are consistent with those obtained from the EOG recordings, which measure the voltage change due to the current flow through the extracellular resistance of the olfactory epithelium from all the receptors being stimulated[8].

Chemoreceptive specificity of both systems was determined with several amino acids and their derivatives. Both olfactory and gustatory responses were strongly influenced by the position of the amino group. Amino acids having an amino group in the α position (those derived from proteins) were the most effective. Olfactory and gustatory receptors were also able to discriminate enantiomeric pairs, indicating that the chemoreceptors involved possess a corresponding chirality. The L-isomer of an amino acid was always more effective than its D-form, although certain D-amino acids were more stimulatory than other L-forms. A major difference, however, between olfactory and gustatory responses to amino acids in the catfish involved the amino acid side chain. Although both chemosensory systems of catfish were able to detect extremely dilute concentrations of amino acids, each system was specific for particular side groups of the amino acids. The more effective amino acid stimuli based on the neural responses of both chemical systems are listed in Fig. 2; however, neither list correlates with the amino acids essential for growth in this species[13].

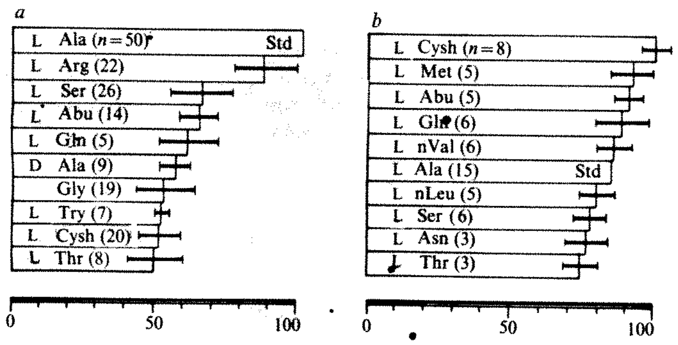

Fig. 2 Comparison of stimulatory effectiveness of the ten most potent amino acids tested on the maxillary barbel and olfactory mucosa at 0.1 mM applied concentrations; estimated concentrations at the receptors were 6×10^{-5} M for the taste (*a*) and 2.5×10^{-5} M for the olfactory (*b*) stimuli as determined by photodensitometry of dye solutions. Relative position of each chemical is represented as a percentage of the response to the standard (Std), 0.1 mM L-alanine. *n*, number of fish tested. Bars indicate s.d.

The taste system was highly responsive to the amino acids of low molecular weight having unbranched and uncharged side chains. A major exception was the response to L-arginine, the second most effective taste stimulus, which is a positively charged, higher molecular weight amino acid. The ability of an amino acid to initiate a large gustatory response fell off rapidly after arginine, and the tenth compound in Fig. 2, L-threonine, elicited a response only 50% of that of the most effective chemical, L-alanine, tested at equal stimulus concentrations.

The olfactory system was not as specific as the taste system and was responsive to a group of amino acids. The sulphur-containing amino acids, L-cysteine and L-methionine, were most effective, with less of a decrease in effectiveness as one proceeds down the order in comparison with taste. The tenth compound, L-threonine, produced a response of approximately 75% of that of the most effective olfactory stimulus tested at equal molar concentration. In general, EOG recordings reflected a similar listing of effective amino acid stimuli, but the order was not identical with that for the neural recordings.

Amino acids are likely to be important in various aspects of fish behaviour. Both cartilaginous and bony fishes orient towards an amino acid source[14–16]; however, the relative importance of olfaction and taste in the detection of the amino acids stimulus and in the initiation of specific behavioral responses is generally unknown. In catfish, conspecific chemical communication by pheromones is thought to be mediated entirely by the olfactory sense[17], and feeding behaviour primarily by the gustatory sense[18]. If certain amino acids or combinations of amino acids provide chemosensory information concerning social or feeding behaviour, then a difference between the olfactory and gustatory receptor responses could code for the appropriate behavioural responses. Although the olfactory and gustatory receptor mechanisms are not understood, each system may have more receptor sites for particular amino acids physiologically relevant to that system.

Whether amino acids such as alanine and arginine, the most effective taste stimuli tested, signal a natural food source in the animal's environment, or whether compounds such as cysteine and methionine, the most efficacious olfactory stimuli tested, are of pheromonal nature, is yet to be determined.

The present experiments indicate that although the olfactory and gustatory systems of the channel catfish are highly sensitive to the α-amino acids, each system responds differently to its chemical environment as determined by electrophysiological recordings.

Calcium utilisation during anaerobiosis induced by osmotic shock in a bivalve mollusc

DURING aerial exposure, some littoral marine bivalve molluscs, for example *Mytilus*[1] and *Mercenaria*[2,3], have been shown to close their valves and respire anaerobically. The major by-product of anaerobiosis in the clam *Mercenaria mercenaria* is succinic acid which is neutralised by the dissolution of calcium carbonate previously deposited in the shell[2,3]. The ability of bivalves to respire anaerobically has been well documented, an early review on this subject[4] records a variety of species which are able to survive long periods in the absence of oxygen. Most evidence for anaerobic metabolism in bivalves is based on observations that on return to aerobic conditions, oxygen consumption rapidly rises to levels above normal[5,6]. A similar 'over shoot' in heart rate has been reported[1,7,8]. These observations have been explained as representing an increase in circulatory and respiratory activity associated with the repayment of an 'oxygen debt' incurred during the period of anaerobiosis. The changeover from aerobic to anaerobic respiration in bivalves has been reported to occur when the oxygen tension of the surrounding water falls to very low levels or to low tide when the bivalves may close the valves[7,9,10]. We report here results which are part of an extensive study of osmotic and behavioural responses of *Scrobicularia plana* (Da Costa), a euryhaline estuarine species, to varying concentrations of seawater and demonstrate the use of calcium from the shell to buffer the products of anaerobiosis. The concentrations of sodium, potassium, magnesium and calcium were measured by atomic absorption spectrophotometry in the body fluids and medium under different conditions of osmotic stress at 10 °C.

When *Scrobicularia* were transferred from aerated 30‰ seawater to aerated 6‰ seawater, the concentrations of Na^+ and other ions, except Ca^{2+}, in mantle cavity fluid and blood fell gradually to the level of the external medium within 14 d (Fig. 1). At first the valves remained closed for long periods but after 7 d pumping activity took place for more than 50% of the time. In contrast to the other ions, the calcium concentration in the blood rose to a maximum value of about 30 mM (about three times the normal concentration in 30‰ seawater) within 5–7 d of the transfer, after which time the concentrations of calcium in all body fluids dropped towards that of the external medium (Fig. 2*a*). From day 18, a low stable level of calcium was maintained comparable with previously published values for other bivalves. Indeed the rise in calcium concentration has not been reported previously because former studies have determined calcium concentrations after a long acclimation period of 3–4 weeks (refs 11–13). The *p*H of the extra-pallial and mantle cavity fluids changes in a manner similar to calcium (Fig. 2*b*).

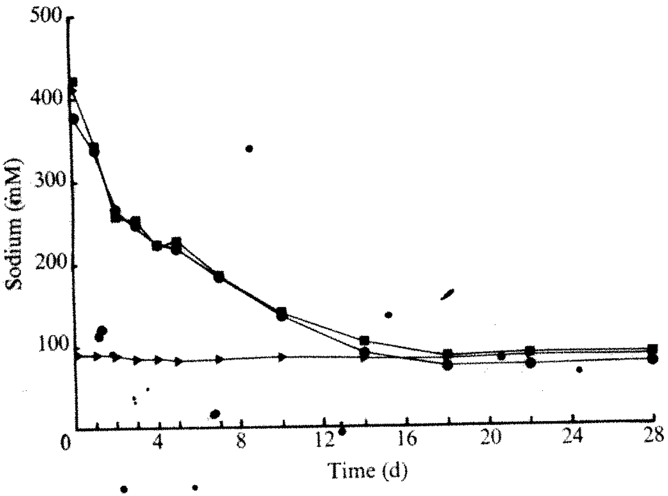

Fig. 1 Na^+ concentrations in *S. plana* transferred directly from 30‰ seawater (day 0) to 6‰ sea water in well aerated conditions (■), mantle cavity fluid; (●), blood from the ventricle; (▲), medium. Each point is the mean of four determinations made on samples pooled from 12–14 individual *S. plana* selected randomly. Throughout the experiment the animals were fed regularly on *Tetraselmis* and the medium was changed every 24 h. Ionic determinations throughout were also made on pericardial fluid and pedal haemolymph with similar results which have been omitted for clarity.

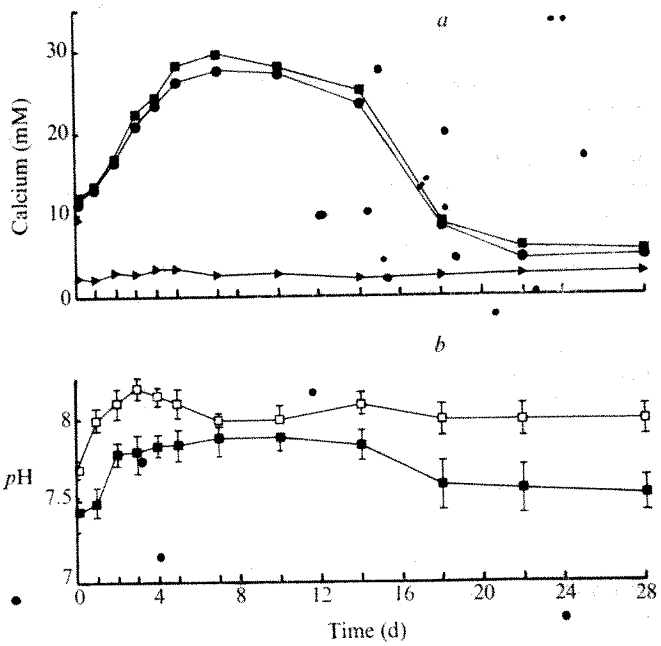

Fig. 2 *a*, Ca^{2+} concentrations of *S. plana* transferred directly from 30‰ seawater (day 0) to 6‰ seawater. Procedure and symbols as in Fig. 1. *b*, *p*H of mantle cavity fluid, medium (symbols as in Fig. 1) and extrapallial fluid (□) from same animals as (*a*). Extrapallial fluid obtained by drilling the right valve between the adductor muscles. Bars represent s.d. of 10 samples from each of 10 animals. Determinations by Ingold micro *p*H assembly with Radiometer, M63 *p*H meter.

The increase in calcium concentration over the first 7 d is correlated with our observations of the behaviour of *S. plana* under these extreme changes in osmotic concentration. Recordings of valve movements and gill pumping activity show that after reduction of the salinity of the medium, animals largely remain closed but gradually expose the mantle tissue and from the seventh day begin to interact more with the medium, the increase of valve movements and pumping activity coinciding with the fall in calcium concentration and *p*H. During the initial period when the valves of *Scrobicularia* are closed, we have shown by microdiffusion and thin layer chromatography that ammonia accumulates in the mantle cavity and that succinic acid is the major organic acid accumulated in the tissues. This has been confirmed by De Zwaan (personal communication).

To determine whether the rise in calcium is due to anaerobic metabolism during the acclimation period, *Scrobicularia* were placed in 30‰ oxygen-free seawater under nitrogen. The calcium levels in all body-fluids rose slightly to 14–16 mM and remained at that level over the 6-d period (Fig. 3*a*, A). During these 6 d the valves remained open. On the sixth day (Fig. 3a, B), the bivalves were osmotically stressed by changing the medium to 6‰ oxygen-free seawater, resulting in valve closure and inactivity. The concentration of calcium increased reaching a maximum of about 30 mM after which it fell towards that of the medium (Fig. 3a, C). The *p*H value of the mantle cavity fluid (over the first 6-d period) is lower than that of the medium, as in *Scrobicularia* respiring aerobically in normal seawater (Fig. 3b), but upon transfer to 6‰ oxygen-free seawater, the *p*H values correspond with those of Fig. 2b. On the 13th day some *S. plana* were closed forcibly by counteracting the hinge ligament with rubber bands and within 3 d the calcium concentrations in the body fluids of these animals increased by 50% (Fig. 3a, D). In *Scrobicularia* kept in 30‰ oxygen-free seawater with their valves forcibly closed, there is a rapid increase in the calcium concentration over a 2-d period to about the same level as those reached by animals in 7 d when subjected to an osmotic shock under aerobic conditions (Fig. 4). After the second day, the valves were allowed to gape normally and the calcium concentrations dropped to normal levels within 2 d. Unlike animals subjected to osmotic shock, those in oxygen-free normal seawater kept their valves open and continued pumping activity. We suggest that continuous water flow through the mantle cavity may explain the lack of a noticeable rise in calcium concentration, for in these conditions no anaerobic metabolites will accumulate and in consequence no buffering will be required.

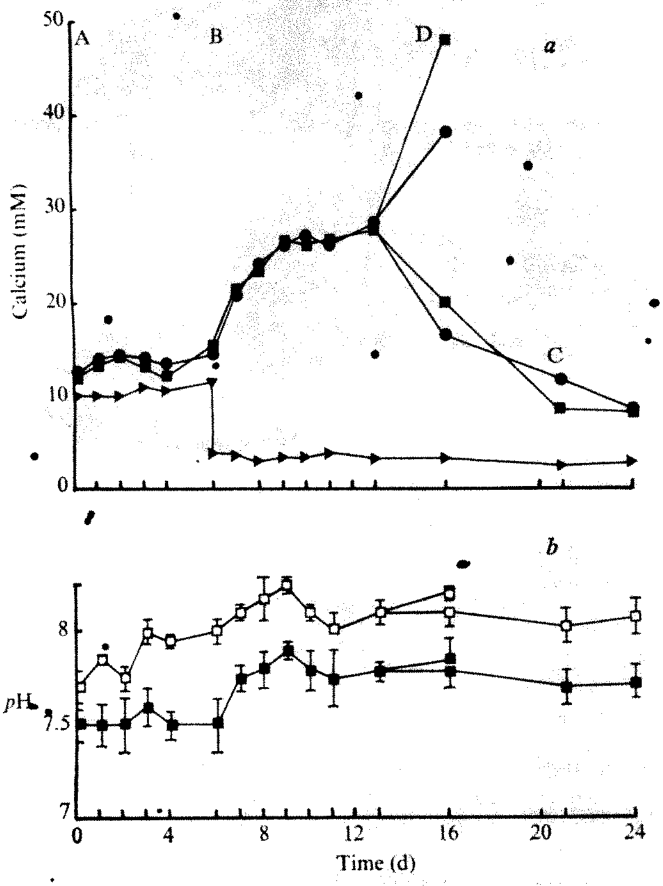

Fig. 3 *a*, Ca^{2+} concentrations of *S. plana* placed in oxygen-free 30‰ seawater on day 0 (A). (Symbols and procedure as in Fig. 1.) After 6 d the animals were additionally subjected to osmotic stress, by immersion in oxygen-free 6‰ seawater (B and C). After a further 7 d the valves of 20 animals were forcibly closed (D). *b*, The *p*H values in animals under the same conditions as Fig. 3 *a*, determined as in Fig. 2.

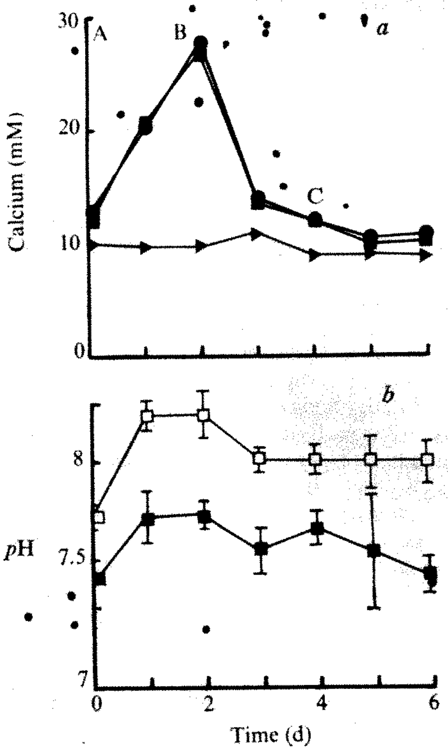

Fig. 4 *a*, Ca^{2+} concentrations and *b*, *p*H values of *S. plana* with valves forcibly closed transferred from aerated 30‰ seawater to oxygen-free seawater (A). After 2 d the bivalves were allowed to gape normally while remaining in the same medium (B). After a further 2 d the medium (30‰ seawater) was aerated (C). Samples and analytical procedure as in Figs 1 and 2.

Adverse environmental conditions, such as osmotic stress, may cause *S. plana* to close its valves for periods of up to 7 d. During prolonged valve closure respiration is anaerobic and, due to lack of ventilation of the mantle cavity, metabolites, for example succinic acid and ammonia, accumulate. A parallel increase in calcium ion concentration, probably by dissolution of the shell, is thought to act as a means of buffering these metabolites during an initial period of acclimatisation to the extreme salinity change.

We thank Mrs P. Yalden for technical assistance.

X-ray microanalysis of freeze-dried ultrathin frozen sections of a regulating epithelium from the snail *Otala*

MANY epithelial cells are known to regulate the flow of water and ions across the epithelium. This has been observed in various animals[1] and is probably an essential feature of all living organisms. Hibernating *Otala lactea* (Mollusca, Gastropoda, Pulmonata) can survive long periods of drought without access to water by regulating the evaporative water loss from the mantle epithelium[2]. Machin[2] has shown that these snails are as efficient as insects at controlling water loss when they are hibernating, yet when they are active and crawling they lose water at the same rate as does a free water surface. To achieve this the animals produce an osmotic gradient across the mantle epithelial cells of approximately 4.5 Osm kg^{-1} from the cell base to the apical plasma membrane[2]. X-ray microanalysis of freeze-dried frozen sections has shown that the levels of silicon, chlorine, potassium, iron and zinc are significantly greater in hibernating (regulating) mantle tissue than in tissues taken from normal actively crawling snails, and a gradient can be observed within these cells.

Hibernating snails were kept in a dry and undisturbed place in the laboratory[2] while others, which were active, were enclosed in a glass tank with lettuce leaves. Small samples (1 mm^3) of mantle tissue were excised from both hibernating and active snails within 20 s of their removal from their containers. The tissue was frozen on to brass specimen holders[5] by immersion into liquid nitrogen slush at −210 °C (ref. 6). Blocks of tissue were carefully trimmed so that the square blockface included a vertical section through the superficial layers of the mantle epithelium. Trimming and sectioning (130 nm) were done in a cryostat containing an ultramicrotome [5,6] at temperatures at which ribbons of ultrathin sections could just be obtained, that is control blocks at −72 °C; regulating at −76 °C. 'Dry' ribbons of sections were pressed into contact with Formvar-coated nickel grids[5–7], freeze dried at their cutting temperatures for 3 h in the cryostat and in the presence of dry nitrogen, warmed slowly to −15 °C overnight and brought to ambient temperature in the presence of dry nitrogen. They were then coated with 20–30 nm of carbon to prevent rehydration[7].

Sections were analysed either in EMMA 4 (analytical electron microscope) equipped with LINK system energy dispersive detector or in the AEICORA analytical microscope (courtesy of Kratos Ltd, AEI Scientific Apparatus). The specimens were held in graphite inserts to reduce the background readings. Analytical conditions were carefully controlled and matched between both instruments—accelerating voltage, 60 kV; beam current as measured by Faraday cage, 4.0 mA; spot size, 100 nm; overall c.p.s., 200–700; counting time 100 s.

Gupta *et al.*[3] have studied the distribution of three ions within an insect Malpighian tubule by analysing hydrated 'thick' frozen sections of 1–2 μm. In our experience there are considerable advantages in the use of freeze-dried ultrathin frozen sections. The morphology of the cells is sufficiently clear to relate the structures seen in ultrathin frozen sections to those seen in sections of conventionally fixed and embedded material. The good resolution in our micrographs is due to the initial thinness of the section and the removal of water by freeze drying. This also means that there is less lateral spread of electrons around the area of the probe and consequently leads to an improvement in analytical resolution with good peak to background ratios.

Analysis of tissue from ribbons of ultrathin sections of consistent thickness makes it possible to express the results by volume (that is $P-b$) rather than by mass (personal communication from H. Höhling). We felt that the results expressed in this way have greater biological significance than relative mass fractions, $((P-b))/W$, where $P-b$ is the integrated peak minus background for an element, and W is the continuum or measurement of mass), provided that sections are of uniform thickness and freeze drying causes no lateral redistribution of labile elements. The continuum measurements for the regulating and control cells showed that there was no significant difference in section thickness (means, where n = at least 30 measurements, regulating 3,382 ± 94; controls 3,387 ± 231). Previous work suggests that there is no significant redistribution of diffusible elements during sectioning or freeze drying, and Gupta *et al.*[3] have claimed that there were no 'parallel changes in either the characteristic counts or the distribution of elements' in their sections before and after drying.

The subcellular detail of the regulating epithelium is shown in the electron micrographs (Fig. 1*a*, *b*, and *c*)[9]. Figure 1*a* shows an ultrathin frozen section and Fig. 1*b* an enlargement of the apical region. The results of the X-ray microanalysis of this and other sections are summarised in diagrammatic form in Fig. 2, and show that in the apical region there is a marked increase in the relative concentrations of both chlorine and potassium, and that there is a significant concentration gradient within the cells of the regulating epithelium from the apical plasma membrane to the nuclear regions at the base of the cells. There is, however, a difference between the 'light' and 'dark' areas of the nuclei: it is not clear at this stage if the 'dark' areas of the nucleus represent the condensed chromatin. There is also a greater variance in the chlorine and potassium data than for the other elements shown in Fig. 2. It may be that this is an indication that these elements are predominantly unbound and that their concentrations are not constant. The lower variances for phosphorus and calcium may be due to the fact that they are at least partially 'bound'.

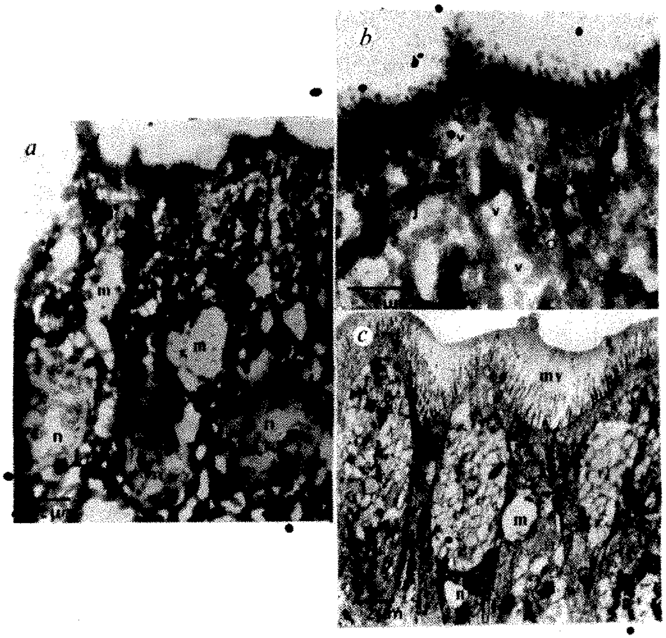

Fig. 1 *a*, Low power electron micrograph of freeze-dried ultrathin frozen section of the regulating epithelium *Otala lactea*. *b*, High power electron micrograph showing the detail in the apical region of the regulating epithelium (from *a*). *c*, Conventionally prepared section of regulating epithelium after fixation and embedding. mv, Microvilli in the apical region; m, mucocyte cells; n, nuclei; j, junctional complexes; v, vesicles (in *b*); lv, (in *c*) laminate vesicles; arrows (*b*) indicate mitochondria; circles (*b*) enclose ice-crystal artefacts.

The silicon levels in the apical region of the regulating epithelium are significantly higher than in the controls (1,011 ± 72 regulating; 685 ± 68 controls). A concentration gradient is established similar to that shown for chlorine and potassium. This cannot be an artefact due to silicon contamination from the glass knives because cutting with diamond knives does not reduce the levels of silicon observed. It cannot be due to contamination from silicon in the oils of the microscope vacuum system because this element is absent from the oils used in our instrument. X-ray microanalysis has also established that there is no silicon in the carbon used to evaporate

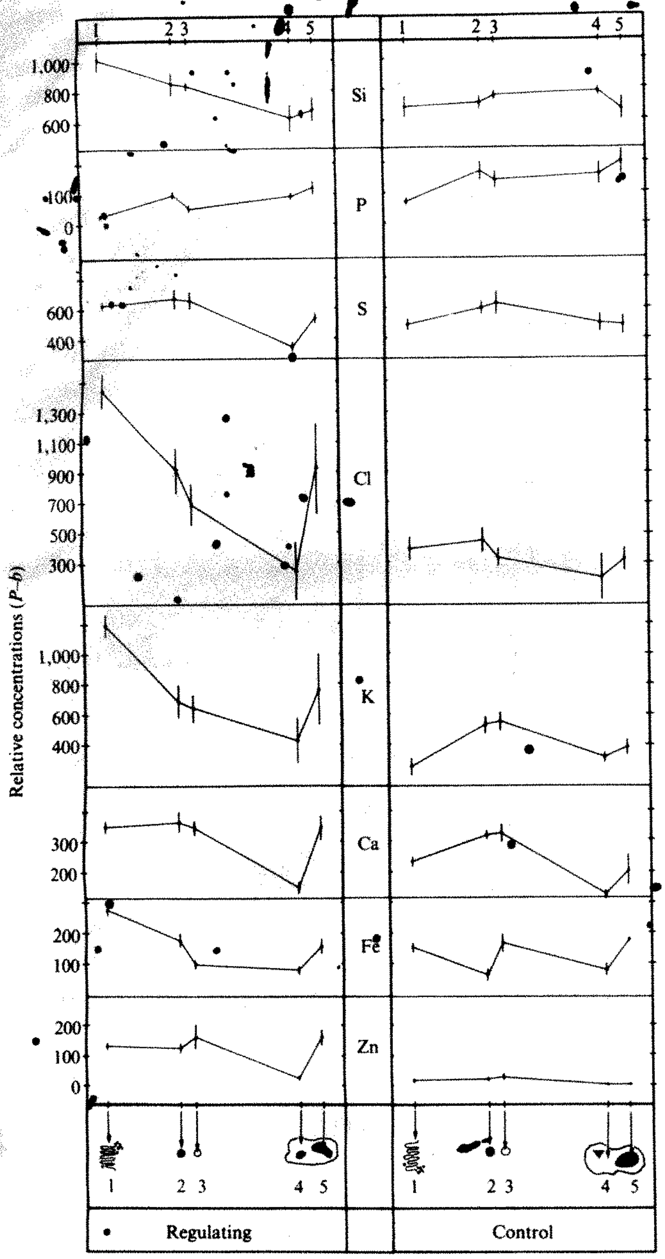

Fig. 2 Elemental composition (by volume) of various elements at four levels with the epithelial cells in regulating and control snails (*Otala lactea*). 1, Apical microvilli region; 2, mitochondria; 3, adjacent ground cytoplasm below each mitochrondria; 4, nucleus 'light areas'; 5, nucleus 'dark areas'. The variances shown are the standard errors of the means and reflect true biological variation rather than errors in acquiring the analytical data. No figures are given for sodium because the sodium levels in general were too low to reflect any significant trends. When potassium levels were high, however, the sodium levels were low. In a few examples the higher sodium levels were always accompanied by lower potassium.

the 20–30-nm layer of carbon over the sections. And it cannot be due to electrons being scattered by the denser organelles, thereby generating silicon X-rays within the lithium-drifted silicon detector, because the mitochondria show a greater electron density but not the highest level of silicon. We feel therefore that silicon may have a greater biological significance than has been assumed.

The changes in concentration of iron and zinc between regulating and control epithelium indicates that these elements are related to fundamental physiological processes within the cells. The increased concentration of zinc, for example, may be related to its role as an enzymatic cofactor associated with carbonic anhydrase, which is known to be present in mantle epithelial tissue[8].

These preliminary results have shown that X-ray microanalysis of freeze-dried ultrathin (130 nm) frozen sections is sufficiently sensitive to detect physiologically significant changes in the concentration of elements at the subcellular level. Further measurements on the elemental composition of structures within these cells are being made and these results will be published in the near future.

Right-left asymmetry of myelin development in epiretinal portion of rabbit optic nerve

DOMINANCE is the priority or preferential activity of one member of any bilateral pair of structures in the body. The phenomenon of dominant hand, foot and eye for example is well known in humans and this basic sidedness is thought to be cerebral in origin. Based on experiments on audiogenic seizures evidence has been produced for an asymmetry of cerebral function in certain inbred strains of mice[1]. In other animal species dogs are known to have preference of paw, and right–left eye dominance in the visual cortex of cats has been demonstrated[2]. Various theories have emerged to explain ocular dominance[3,4]. It is generally accepted that this is not associated with significant structural differences between the two halves of the brain[5]. Apart from morphological evidence for left–right asymmetrics in temporal lobes of speech regions[6], very little evidence for anatomical differences has been produced in humans or other animals. The rabbit retina is unique in having bundles of myelinated nerve fibres extending equatorially from the optic disk, which are unmyelinated at birth but in which myelination begins at 9–10 days of age[7]. I present here results which indicate that the sequence of myelination is asymmetrical between the right and left eyes, one being dominant.

Rabbits are born with closed eyes which open on the 10th day after birth. I noted that 19 out of 24 rabbits opened the right eye first followed by the left several hours later while the remaining 5 rabbits opened the left eye first.

The optic nerve enters the retina 3–4 mm above the midbrain from the optic head and extends nasally and temporally into two bands of 'medullary rays'. The epiretinal strips were dissected after whole body perfusion with 4% glutaraldehyde[7] and immersed in 1% osmic acid. The eye which opened first showed blackening of the fibres at a comparatively faster rate than the other eye (Fig. 1*a*, *b*). These empiretinal strips were embedded as previously described[7].

Serial 1 µm sections were cut from nasal to temporal side of the epiretinal strips of both right and left eye from 24 animals; 12 more rabbits were also included in this study. The sections from the 9-d-old rabbit showed only a few myelinated nerve fibres close to the disk of one eye, while no myelinated fibres were present in the other (Fig.

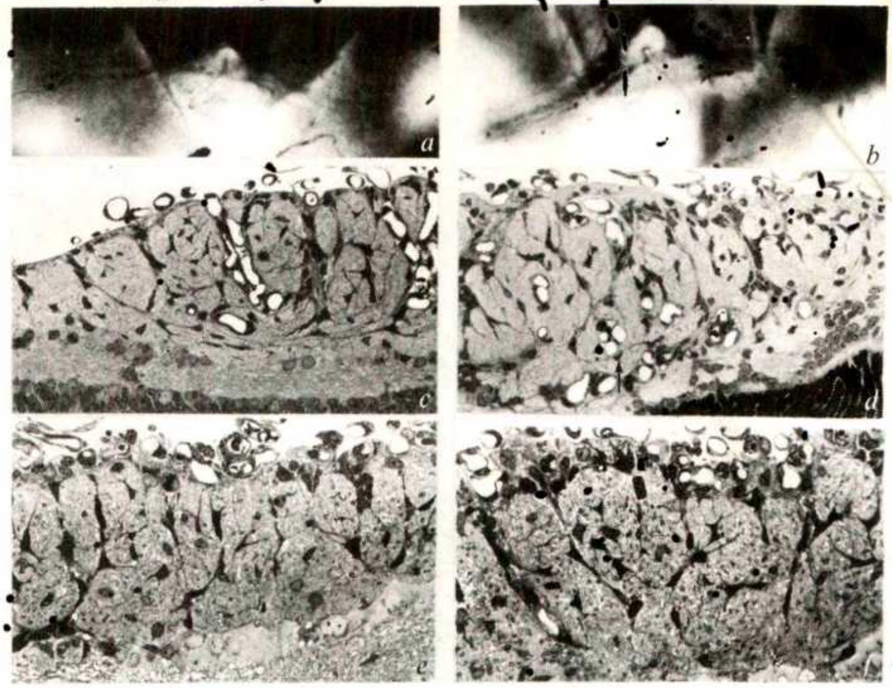

Fig. 1 *a*, *b*, Epiretinal portion dissected from 9-d-old rabbit. Left (*a*) and right (*b*) eye photographed 15 min after osmication. Note the intensity and size difference of the L–R strip. *c*, *d*, 1 μm section from 9-d-old rabbit of left (*c*) and right (*d*) eye epiretinal strip through the optic disk stained with toluidine blue showing a few myelinated fibres in the right strip (*d*) (arrow). ×160. *e*, *f*, Left (*e*) and right (*f*) eye epiretinal strip section through the optic disk of 10-d-old rabbit. Note the dominant myelinated fibres in right (*f*) eye. ×160.

1*c*, *d*). The right eye was usually more advanced than the left.

From the 10th day onward, both eyes show myelinated fibres, but where the right eye opened first, the number of myelinated fibres was much greater than in the left eye which opened several hours later (Fig. 1*e*, *f*). In cases where the left eye opened first the left eye was more advanced in the number of myelinated fibres. This anatomical feature of myelin dominance was difficult to see later than 22 d after birth. The nasal and temporal halves of the strip of each eye are also asymmetrical in both size and development of myelin sheaths, the latter side being dominant.

Examination of 1 μm sections from right and left optic nerves from 1–3-d-old rabbits also showed that earlier myelination of the nerve fibres in the right eye occurred in about 75% of the animals, and earlier myelination of the left was seen in 25%.

In the adult rabbit the anatomical asymmetry which exists during early development could not be observed morphologically. It was, however, demonstrated by light stimulation studies.

It is likely that the earlier onset of myelination in one eye is associated with the dominant brain hemisphere, which during development would most probably show morphological asymmetry, possibly one side (half of body) developing at a comparatively faster rate rather than the size difference betwen the two halves of the hemisphere. The ratio 3 : 1 between the right–left dominance suggests that the mechanism is genetically controlled.

It is tempting to draw a comparison between the asymmetry in rabbit and man in that the cortical dominance may be due to early maturation of one half of the hemisphere and nerve fibres arising from it rather than neurone size.

New type of representation for mapping chain-folding in protein molecules

Conformational details of small molecules can easily be visualised in the usual stereo diagrams used by crystallographers, but such details cannot be readily visualised for protein molecules made up of thousands of atoms. For such large molecules special types of representations become necessary for depicting their three-dimensional structure, in the form of two-dimensional diagrams. In view of this, many attempts to represent the conformational details in protein molecules, have been reported[1–7]. I present here a new method for mapping the folding of the backbone polypeptide chain of protein molecules. This representation brings out all the features of protein folding, with no degeneracy caused by depicting the conformational details, and is useful in readily recognising all the secondary structures, without ambiguity, as one progresses along the chain.

The backbone conformation of a protein chain can be completely specified by the twin dihedral angles (φ, ψ)[8] since the 'peptide unit' can be taken to be planar for all practical purposes. (There are some indications that the peptide unit is nonplanar[9,11], but the deviations from planarity can be considered to be very small when compared to the full range of variations for the dihedral angles φ around the single bond $N—C^\alpha$ and ψ around $C^\alpha—C$.) It has become customary to plot the (φ, ψ) values at each C^α-atom of a protein molecule in the Ramachandran map to show how the dipeptide conformations conform to the limits of the hard-sphere and soft-sphere models in the (φ, ψ) map[12]. But the details of the secondary structures as one progresses along the chain are not readily available in this representation. In order to achieve this, some single parameters have been developed to be used in chain plots[5,6], but there is an inevitable degeneracy in these chain plots, since many conformations will give rise to the same value for such a single parameter representing a particular residue.

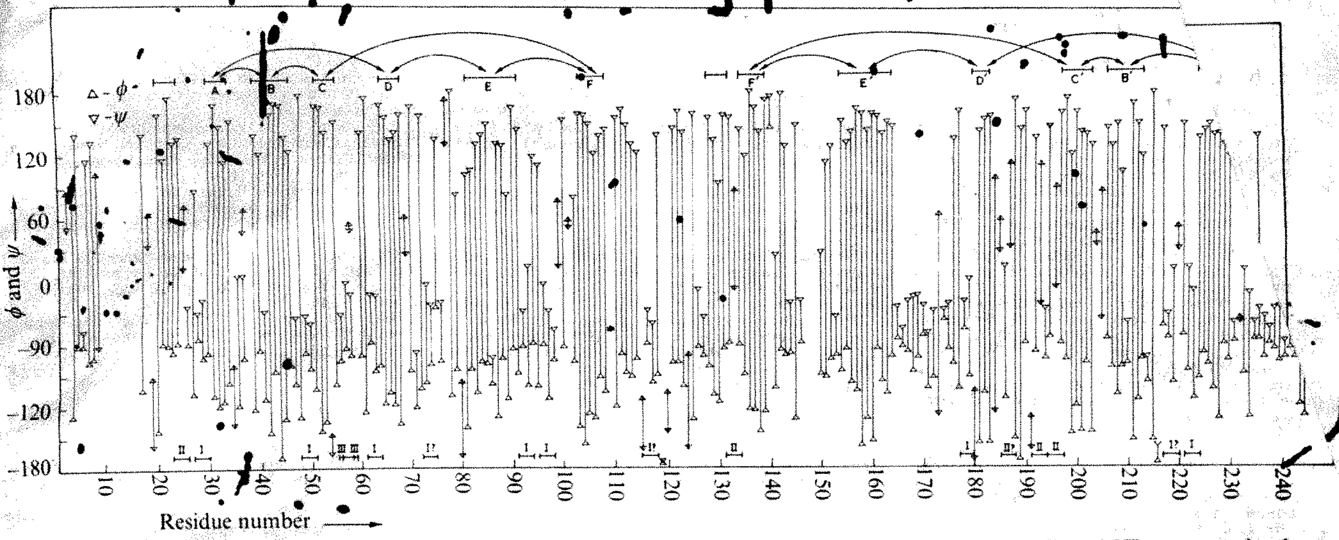

Fig. 1 The new type of mapping for the protein molecule α-chymotrypsin. △, φ values; ▽, ψ values. I, II and III represent the three types of bends. The arrow-headed bows indicate the bonding mates of the β-stretches A, B and so on. For further details see text.

The following chain representation overcomes the difficulties mentioned above, and seems to give a good overall picture of the folding of the protein molecule as one progresses along the chain.

The residue numbers are sequentially taken along the X-axis and the corresponding φ and ψ values are plotted along the ordinate with different symbols. Symbol Δ is chosen for φ and, ∇ for ψ. For proper visual effect these two symbols for a given residue are joined by a vertical line. This kind of chain representation for mapping of protein folding is shown in Fig. 1 for the case of α-chymotrypsin (ref. 13).

In this representation the α-helices are seen as stretches of short vertical lines around −55° on the ordinate (see, for example, residues around 240). The β-stretches are seen as stripes of long vertical lines encompassing almost the whole range of the ordinate (see for example, residues around 225).

The three types of bend conformations[13,14] or loops can be at once recognised and identified in this kind of map. The residues corresponding to the three types of loops are marked as I, II and III at the bottom of Fig. 1; characteristically, loop I has two short lines sandwiched between two long lines (see for example residues 27–30); loop II has a similar pattern, but the third residue has ψ value less than the φ value (see for example residues 23–26). Loop III is simply a part of 3.0_{10}-helix and an example is seen in the residues 55–59. It should be noted that changes from these characteristic patterns would give tell-tale evidence of distortion in the loops. In Fig. 1 such distorted loops have been marked with a question-mark and these agree well with the observations of Birktoft and Blow[13].

Important feature of the folding in α-chymotrypsin are the two approximately similar domains, each having a 'barrel' of anti-parallel β-sheets, termed cylinder I and II by Birktoft and Blow[13]. Each cylinder is made up of six anti-parallel β-stretches, each of which is hydrogen-bonded to two neighbouring β-stretches, and thus forming a barrel. The six β-stretches have been marked by horizontal lines just above the corresponding plots in Fig. 1. They have been labelled A, B, C, D, E, F in cylinder I and A′ B′ C′ D′ E′ F′ in cylinder II, following Balasubramanian[15]. The bonding mates of each of the β-stretches have also been indicated by arrow-head 'bows'. The broad similarity between the patterns in this mapping for cylinder I and II is obvious.

Shotton and Watson[16] found reverse internal homology in tosyl elastase and extended the idea to α-chymotrypsin which belongs to the same family of proteins—the serine proteases. Nishikawa and Ooi[17] also contend that the primary structures of the two similar domains correspond to each other in the opposite sense; that is, residues 29 to 112 correspond to residues 230 to 133 in an approximate way. Hence the β-stretches involved in the cylindrical domains have been appropriately labelled[15], and an approximate mirror symmetry can be seen in the map (Fig. 1), with the mirror situated near residue number 122. But a closer look may justify a translational symmetry too. It is readily seen that for the β-stretch of residues 20–24, there is a corresponding one of residues 128–132 (these sequences of residues can in a way be called β-stretches, though there are no regular hydrogen bonds with a neighbouring extended conformation); these stretches precede the stretches of residues forming the similar domains. However, in the distorted β-stretch B, there is a 'break' at residue 41 (a short vertical line) and correspondingly, there is one at 210 in the distorted β-stretch B′. The paradoxical existence of both the approximate mirror symmetry and translational symmetry in the map arises because there is already an approximate mirror symmetry in the stretches 29–112 corresponding to cylinder I and 133–230 corresponding to cylinder II (a mirror could be 'placed' near residue 60 and another near residue 190). Due to the distortions in the similar domains[13], one cannot resolve the question unequivocally. Nevertheless, this type of mapping is very useful for observing such intrinsic details of chain folding.

The method of mapping chain folding in protein molecules presented here seems to have many advantages over many other types of representations reported in the literature, and can be used as a uniform and stereotyped 'finger printing' for all protein molecules.

Philosophical Transactions of the Royal Society of London. A: Mathematical and Physical Sciences. Vol. 284., No. 1324: On Topographically Identifiable Sources of Cathodoluminescence in Natural Diamonds. By P. L. Hanley, I. Kiflawi and A. R. Lang, FRS. Pp. 329–368 + plates 1–8. (London: The Royal Society, 1977.) UK £4.70; Overseas £4.80. [93

Office of Population Censuses and Surveys. Mortality Statistics: Cause, 1974. (Review of the Registrar General on Deaths by Cause, Sex and Age, in England and Wales, 1974. Series DH2, No. 1.) Pp. iii + 82. (London: HMSO, 1977.) £2 net. [93

Brain Drain and Income Taxation: a UK Case Study. By Peter Balacs and Anne Gordon. (*World Development*, Vol. 3, No. 10, October, 1975.) Pp. 677–703. (Oxford and New York: Pergamon Press, 1976.) $9. [103

Department of Energy. Fuel Efficiency Booklet No. 9: How to Make the Best Use of Condensate. Pp. 16. (London: Department of Energy, Thames House South, Millbank, SW1, 1977). [103

Computerized Tomography, Vol. 1, No. 1, 1977. (The International Journal of Radiological Diagnosis Using CT Scanners.) Pp. 1–130. Annual subscription: 1 volume of 4 issues $65. (Oxford and New York: Pergamon Press, 1977). [103

Headquarters Library, Department of the Environment. Research and Surveys 1975. (Information Series Lib/Inf/23.) Pp. v + 197. Research and Surveys 1976. (Information Series Lib/Inf/24). Pp. v + 348. (London: Librarian (Research), Headquarters Library, Room P3/008D, Departments of the Environment and Transport, 2 Marsham Street, SW1, 1976 and 1977) *gratis* [113

Mentally Handicapped Children: a Plan for Action. (Pamphlet No. 2). Pp. iv + 45. (London: National Development Group for the Mentally Handicapped, Alexander Fleming House, London, SE1, 1977). [113

Wind Engineering, Vol. 1, No. 1, 1977. Edited by E. Mowforth Pp. 1–90 Published quarterly. Price: (multi-user organization) £20; (individuals whose organisation subscribes) £5. (London: Multi-Science Publishing Company, The Old Mill, Dorset Place, E15, 1977.) [153

National Physical Laboratory. Measurement of Force by Elastic Devices. By B. Swindells and R. C. Debnam. Pp. v + 34. (London: HMSO, 1977.) £1.40 net. [173

The Wellcome Trust. 1974–76. Eleventh Report. Pp. 148 (London: The Wellcome Trust, 1 Park Square West, NW1, 1977.) [173

The British Library. Research and Development Reports. Report No. 5325 HC: Review Committee on Education for Information Use—Final Report. P. 28. (London: The British Library, Research and Development, Sheraton House, Great Chapel Street, W1, 1977.) £2. [183

Grassland Research Institute. Technical Report No. 18: Enclosure Method for Measuring Photosynthesis, Respiration and Transpiration of Crops in the Field. By W. Stiles. Pp. 42. (Hurley, Maidenhead: Librarian, The Glassland Research Institute, 1977.) £2. [183

National Radiological Protection Board. NRPB-R48: Assessment of the Radiological Protection Aspects of Disposal of High Level Waste on the Ocean Floor. By P. D. Grimwood and G. A. M. Webb. Pp. iv + 117. (Harwell, Didcot, Oxon: National Radiological Protection Board, 1976.) [233

Memorandum of Evidence from the Association of the British Pharmaceutical Industry to the Royal Commission on the National Health Service. Pp. 13. (London: The Association of the British Pharmaceutical Industry, 162 Regent Street, W1, 1977.) [233

First Special Report from the Expenditure Committee, Session 1976–77, National Parks and the Countryside. (Observations by the Secretaries of State for the Environment, for Scotland and for Wales on the Sixth Report of the Committee in Session 1975–76). Pp. 14. (London: HMSO, 1977.) 35p net. [2

Philosophical Transactions of the Royal Society of London. B: Biological Sciences. Vol. 277, No. 954: The Nitrogen Cycle: Perturbations Due to Man and Their Impact on Atmospheric N_30 and 0_2. By M B. McElroy, S. C. Wofsy and Y. L. Yung. Pp. 159–181. UK £1.40; Overseas £1.45. Vol. 277, No. 955: A Discussion on the Meiotic Process. Organized by R. Riley, FRS, M. D. Bennett and R. B. Flavell. Pp. 183–376. UK £16.80; Overseas £17.30. (London: The Royal Society 1977.) [243

Displays for Man-Machine Systems. (International Conference, 4–7, April, 1977. Conference Publication No. 150.) Pp. vii + 141. (London: The Institution of Electrical Engineers, 1977.) [243

The Reorganised NHS. Pp. 34. (London: Office of Health Economics, 162 Regent Street, W1, 1977.) 70p. [243

Imperial Cancer Research Fund. Annual Report and Accounts, 1976. Pp. 43. Scientific Report to the Council by the Director of Research for the year 1976. Pp. iv + 156. (London: Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2, 1977.) [253

The Future Supply of Nature-Made Oil and Gas. (A Summary Report on the Conference Jointly Organized by the United Nations Institute for Training and Research and the International Institute for Applied Systems Analysis, held 5–16 July 1976 at Schloss Laxenburg, Laxenburg, Austria.) Pp. 29. (Oxford and New York: Pergamon Press, 1977.) [253

Public Health Risks of Exposure to Asbestos. (Report of a Working Group of Experts prepared for the Commission of the European Communities, Directorate-General for Social Affairs, Health and Safety Directorate.) Rapporteur: Professor R. L. Zielhuis. Pp. 149. (Oxford and New York: Pergamon Press, 1977.) £6.75; $12. [283

Histopathology, Vol. 1, No. 1, January 1977. Edited by R. Cotton. Pp. 1–86. Published bi-monthly. Annual subscription: UK £27; Overseas £32.50; USA and Canada $80. (Official journal of the British Division of the International Academy of Pathology.) (Oxford: Blackwell Scientific Publication, 1977.) [283

National Radiological Protection Board. The work of the NRPB 1974/76. Pp. 73. (Harwell, Didcot, Oxon: National Radiological Protection Board, 1977. Obtainable from HMSO, London.) £2. [283

Philosophical Transactions of the Royal Society of London. A: Mathematical and Physical Sciences. Vol. 284, No. 1325: Fast Magnetic Field Line Reco nection. By A. M. Soward and E. R. Priest. Pp. 369 417. (London: The Royal Society, 1977.) UK £2.9 Overseas £3.05. [28

Current Research in the University of Cambridge. Pp. 35. (Cambridge: Secretrry General of the Faculties, The University, 1977.) [28

A Guide to Hazard and Operability Studies. Pp. 42. (London: Chemical Industry Safety and Health Council of the Chemical Industries Association, 93 Albert Embankment, 1977.) £4.50. [30

London School of Hygiene and Tropical Medicine Report on the work of the School, 1975/1976. Pp. 141 (London: London School of Hygiene and Tropica Medicine, 1977.) [30

University of Cambridge: Department of Engineering. Report of the Head of the Department for the Academic Year 1975–76. Pp. 20. (Cambridge: The University, 1977.) [303

Tate and Lyle Group Research and Development Annual Report for 1976. Pp. 40. (Whiteknights, Reading: Philip Lyle Memorial Research Laboratory, 1977.) [303

Other countries

Australia: Commonwealth Scientific and Industrial Research Organization. Annual Report of the Division of Animal Health for 1975. Pp. 127. (East Melbourne: CSIRO, 1976.) [23

United States Department of the Interior: Geological Survey. Professional Paper 574–G: *Q*–Mode Factor Analysis of Geochemical and Petrologic Data Matrices with Constant Row-Sums. By A. T. Miesch. Pp. v + 47. Professional Paper 863: Smaller Foraminifera From Deep Wells on Puerto Rico and St. Croix. By Ruth Todd and Doris Low. Pp. iii + 32 + 12 plates. Professional Paper 987: Physical, Chemical, and Biological Aspects of Subsurface Organic Waste Injection near Wilmington, North Carolina. By J. A. Leenheer, R. L. Malcolm and W. R. White. Pp. iv + 51. (Washington, DC: US Government Printing Office, 1976.) [23

Fire Research, Vol. 1, No. 1, 1977. Edited by I. N. Einhorn, in association with S. C. Israel and J. H. Petajan. Published bimonthly. Pp. 1–66. Subscription price for 1977 (Vol. 1): Sfr. 155.00 (approx. US $59.50) including postage. (Lausanne, Switzerland: Elsevier Sequoia, S.A., P.O. Box 851, 1977.) [33

American Museum Novitates, No. 2612: Notes on the Characoid Subfamily Iguanodectinae, with a Description of a New Species. By Richard P. Vari. Pp. 1–6. (New York: American Museum of Natural History, 1977.) 70 cents. [33

INCO Limited 1976 Annual Report. Pp. 36. (Toronto and London: INCO Limited, 1977.) [43

Control Data Corporation. 1976 Annual Report. Pp. 36. (Minneapolis: Control Data Corporation, 1977.) [43

Legislative Action to Combat Smoking Around the World: a Survey of Existing Legislation. Pp. 27. (Geneva: WHO; London: HMSO, 1976.) Sw.fr.6; $2.40. [73

Environment Canada: Fisheries and Marine Service. Technical Report Np. 686: Physical, Chemical, and Biological Parameters of the Saint John River Estuary, New Brunswick, Canada. By C. D. Metcalfe, M. J. Dadswell, G. F. Gillis and M. L. H. Thomas. Pp. v + 42. (St. Andrews, N.B.: Research and Development Directorate, Biological Station, 1976.) [73

United States Departm3nt of the Interior: Geological Survey. Professional Paper 959: Geology and Resources of Titanium. By E. R. Force, *et al*. Pp. 76. Professional Paper 1013: Glass Reference Standards for the Trace-Element Analysis of Geological Materials—Compilation of Interlaboratory Data. By Alfred T. Myers, Raymond G. Havens, Jon J. Connor, Nancy M. Conklin and Harry J. Rose, Jr. Pp. iii + 29. (Washington, DC: US Government Printing Office, 1976. [73

United States Naval Observatory. Circular No. 154: The Determination of Universal Time at the U.S. Naval Observatory. By Dennis D. McCarthy. Pp. 11. Circular No. 155: Almanac for Computers, 1977. By George H. Kaplan, LeRoy E. Doggett and P. Kenneth Seidelmann. Circular No. 156: Solar Eclipses of 1977. Annular Solar Eclipse of 18 April 1977. Total Solar Eclipse of 12 October 1977. By Alan D. Fiala. Pp. 39. (Washington, DC: U.S. Naval Observatory, 1976.) [83

National Research Council Canada. Associate Committee on Scientific Criteria for Environmental Quality. Status Report, January 1977. Pp. 78. (Ottawa: National Research Council Canada, 1977.) [83

AB Atomenergi 1975/76. Pp. 41. (Nykoping 1: Studsvik, AB Atomenergi Sweden 1976.) [93

Smithsonian Contributions to Zoology. No. 226:5 Observations on the Myology of *Dugong dugon* (Müller). By Daryl P. Domning. Pp. iii + 57. (Washington, DC: Smithsonian Institution Press, 1977. For sale by US Government Printing Office.) [93

Energy, Mines and Resources Canada. Geological Survey of Canada. Bulletin 261: Geology of Lower Ordovician Fossiliferous Strata Between Virgin Arm and Squid Cove, New World Island, Newfoundland. By Gregory S. Horne. Early Ordovician (Late Arenig) Brachiopods from Virgin Arm, New World Island, Newfoundland. By Robert B. Neuman. Pp. 61 (8 plates). $2.40. Paper 75–35: Superficial Geology and Landslides of Thurso-Russell Map-Area, Ontario. By N. R. Gadd. Pp. 7. $3. Paper 75–42: Gravity and Magnetic Fields of the Gulf of St. Lawrence, Canada. By Richard T. Haworth and J. Brian MacIntyre. Pp. iii + 11. $3. Paper 76–8: The Geology of the Bonnet Plume Basin, Yukon Territory. By D. K. Noss Norris and W. S. Hopkins, Jr. Pp. 20. $3.60 Paper 76–24: Dinoflagellat Cyst Terminology. By W. R. Evitt, J. K. Lentin, M. E. Millioud, L. E. Stover and G. L. Williams. Pp. 11. $3 (Ottawa: Geological Survey of Canada, 1976 and 1977 [9
